Moreover, it is the good men we most want: for instance, men over military age who have filled or are filling good positions in the electrical profession, who have arrived at the stage when they might normally take things a little easier after the strenuous life which this profession always imposes on its devotees, but who are willing now to defer their rest a little longer in view of the national emergency.

Applications for enrolment, on the form published in our last issue (p. vii), should be sent to the Editor of ELECTRICAL ENGINEERING, 203 Temple Chambers, London, E.C., who will be pleased to reply to any inquiries for further information, and from whom also further application forms may be obtained.

THE DEVELOPMENT COMMITTEE OF THE I.M.E.A.

AT a meeting on Friday, April 16th, a report was received from the Publicity Sub-Committee on the work done with regard to a preparatory scheme for the production of printed matter on a co-operative basis. The Sub-Committee also reported that Mr. Dunlop, on behalf of the British Electrical and Allied Manufacturers' Association Council, had very kindly offered the use of offices and clerical assistance in connection with the routine work of purchase and distribution of such printed matter, at least during the early stages of the Sub-Committee's work. The Committee expressed their appreciation of this offer. It was resolved that Mr. Courtenay, of the General Electric Company, should act on the Publicity Sub-Committee in place of Mr. C. Palmer, at present on active service.

A report was also received from the Electrical Installations Sub-Committee, and considered. A report was also received from the Domestic Appliances Sub-Committee, outlining a preliminary scheme for certain technical investigations, which the Committee hope to put in hand at an early date. The Committee recommended the inclusion of Mr. Shaw, of Worcester, and Mr. Wilmshurst, of Derby, as members of this Sub-Committee. Also, that from time to time members of manufacturing firms should be co-opted for advice and assistance in regard to specific objects which might be considered helpful to the work of the Development Committee.

In general discussion arising out of the work of the Committee, the point was made that although depletion of staffs arising out of the war, and restrictions placed on borrowing money must, in the nature of things, considerably hamper development work, yet there remained with most undertakings a large amount of new business to be obtained with very little expenditure, and therefore there still existed room for selective canvassing and publicity work, which might be directed to helping manufacturers and traders under the present difficult conditions, if electricity supply were put forward, more particularly in regard to power, on the strength of its real time and labour-saving advantages, and not merely as an improvement on existing conditions. The Secretary reported the correspondence he had had with Mr. Wakeman, Society for Electrical Development, New York, and the Committee instructed him to thank Mr. Wakeman for material sent and offers of assistance and co-operation, which the Committee appreciated very much, and hope that under more favourable conditions in the near future further development in this direction might become possible. The next meeting of the Development Committee will take place on June 16th, 1915, at 2.30 p.m.

ELECTRICAL TRADE WITH BELGIUM AFTER THE WAR

WE have been favoured by a visit from Mr. R. Steylaers, a Belgian electrical engineer now in this country, who is already endeavouring to stimulate British manufacturers into taking an interest in Belgian electrical trade after the war. Mr. Steylaers explained to us the extremely strong position of Germany in Belgian electrical trade before the war; with the exception of a few Belgian manufacturers of electrical machinery, practically the whole of the Belgian trade was in the hands of German firms, principally the A.E.G. and the Siemens-Schuckert groups. The wholesale houses were in many cases, he informs us, more or less under German control, and the country had become accustomed to German methods and designs. There will, it is true, be an enormous amount of electrical work wanted during the re-building of Belgium. Much havoc has been done, and still more will be done before the Germans evacuate the country; Mr. Steylaers even believes that copper lines and cables have already been taken away from all but the more important towns, in view of the shortage of copper for ammunition. It is very early yet to form definite plans when the new conditions are absolutely unknown, and the important question of capitalisation has yet to be considered; but Mr. Steylaers thinks otherwise, and urges an immediate organisation of the means to oust German electrical enterprise from Germany, so as to be ready at the instant the critical moment arrives. Although he has, so far, not found British manufacturers eager to take up the matter at the present time, when their thoughts and activities are all concentrated on the present calls upon their resources, he has received the support of the British Chamber of Commerce, and is, on his own behalf, endeavouring to bring together a number of manufacturers of various electrical specialities to work in connection with a "Union of Belgian Electricians," which he proposes to form, and for which, we understand, he hopes to obtain the necessary capital without calling upon the manufacturers themselves either to provide this or to give inordinately long credit. A meeting, held under the auspices of the London Chamber of Commerce, on May 27th, met with practically no response from manufacturers, but it is proposed to issue invitations for another meeting in a few weeks' time.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 3rd, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

10,275/14. Petrol-Electric Transmission. P. BILES. Electric transmission gear for automobiles of the kind in which the engine drives one member (armature or field system) of a dynamo, while the other element is connected mechanically to the shaft driving the road wheels, as well as to one member of a motor, the other member of which is stationary. In this improvement the speed of the driving shaft is varied by shunting more or less of the field of the series motor. (One figure.)

11,436/14. Protection of Alternators. B.T.-H. Co. and F. H. CLOUGH. Method of protecting an alternator, in which the armature conductors of one phase are separated from those of another by an earthed shield connected to an automatic circuit-breaker. (Three figures.)

11,739/14. Third Rail Insulators. B.T.-H. Co. (*G.E. Co., U.S.A.*). A method of supporting under-running and other back conductors, in which the bracket carrying the conductor is clamped between two insulating blocks held by a bolt extending through them. (Four figures.)

11,794/14. Circuit Breakers. D. K. MORRIS and MORRIS and LISTER, LTD. Circuit breakers, in which a blow-out effect is produced by the action of the current itself, without electromagnets. The apparatus is arranged so that the conductors leading to the contact are close together and parallel, or at a very acute angle for a portion of their length. A movable shutter is also provided, which moves into position between the contact surfaces when the circuit is broken. (Four figures.)

18,143/14. Conduit Fittings. M. J. RAILING and J. T. TAYLOR. These fittings have plain side lugs drilled and tapped throughout their thickness, and provided with tangential binding screws, with or without plain or serrated washers. The screw-heads or the washers partially enter openings in the fittings above the lugs, and, when the screws are tightened to clamp the fitting and tube firmly together, scrape or cut the tube to ensure good electrical continuity. (Two figures.)

22,435/14. Electromagnetic Switches. T. E. BARNUM and W. E. DATE. Electromagnetic switches or contactors of the lock-out type controlled by separate and opposing electromagnets energised by a common current, which, if it does not exceed a predetermined value, operates to close the switch; but, if it does exceed that value, prevents the closing of the switch. (Three figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: ST. HELENS CABLE & RUBBER Co. and WHITE [Connection boxes] 11,889/14.

DYNAMOS, MOTORS AND TRANSFORMERS: ZIMMERMAN (Commutators) 5,848/15.

ELECTROMETALLURGY AND ELECTROCHEMISTRY: DETTIFOSS POWER Co. and LIDHOLM [Production of cyanamide] 3,545/14.

Heating and Cooking: BERRY [Heating apparatus] 12,551/14.

IGNITION: FORD [Magneton] 12,350/14.

INSTRUMENTS AND METERS: BRITISH INSULATED & HELSBY CABLES, LTD. and WILSON [Meters] 12,386/14; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Induction meters] 15,868/14.

Storage Batteries: COLES [Secondary batteries] 18,092/14.

SWITCHGEAR, FUSES AND FITTINGS: SIMPLEX CONDUITS, LTD. and WATERHOUSE [Conduit fittings] 12,599/14; WHARRAM [Locking and anti-vibrating lamp-holders] 12,906/14; HIGHFIELD and DUDDELL [Protective inductances] 15,356/14.

TELEPHONY AND TELEGRAPHY: LENZ [High-frequency rectifier] 13,374/14; PIERCE [Relays] 15,681/14; WESTERN ELECTRIC Co. (*Woodward* for *W.E. Co., U.S.A.*) [Automatic telephones] 17,004/14; THOMPSON [Telephone-call meters] 21,904/14.

Traction: WILSON [Car lighting] 11,841/14; GENDERS and GENDERS [Electrical locking of carriage doors] 11,987/14; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Self-propelled vehicles] 12,047/14; WRIGHT [Train control] 16,880/14.

MISCELLANEOUS: THEEDAM [Colliery signalling] 12,885/14; THOMAS and STOTT [Primary batteries] 13,095/14; SENCE [Electric hair-brushes] 16,612/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

DYNAMOS, MOTORS, &c.: SIEMENS SCHUCKERTWEBKE GES. [Dynamos] 6,997/15; KETTERING, JUNR. [Engine-starting motors] 7,013/15; MILTON [Generators] 7,374/15.

MISCELLANEOUS: DE CAPITANI [Manufacture of tapes containing parallel electric wires] 7,016/15.

Opposition to Grant of Patents

1,341/14. Combined Starting Motor and Lighting Dynamo. A. H. MIDGLEY and C. A. VANDERVELL. A grant has been allowed in this specification, in spite of opposition. The specification describes a machine with separate commutators and armature windings for use in its two functions. The field windings, which as a self-regulating dynamo leave half the poles unexcited, are re-grouped to give the full number of poles when working as a motor.

The following are the more important Patents that have become void through non-payment of renewal fees.

DISTRIBUTING SYSTEMS, CABLES AND WIRES, INSULATING MATERIALS, &c.: E. WITZENMANN [Flexible cable armouring] 3,917/09.

DYNAMOS, MOTORS AND TRANSFORMERS: B.T.-H. Co. (*G.E. Co., U.S.A.*) [Control of single-phase motors] 3,884/04; R. D. MERSHON [Dynamo, motor, and transformer windings] 4,175/07.

INCANDESCENT LAMPS: A.E.G. [Centrifugal mercury vacuum pumps] 4,180/07; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Carbon filaments treated with silicon] 4,364/07; H. KUZEL [Shaping metal filaments by loading with a weight when hot] 1,332/09.

INSTRUMENTS AND METERS: COMPAGNIE ANON. CONTINENTALE POUR LA FABRICATION DES COMPTEURS À GAZ ET AUTRES APPAREILS [Induction meters] 8,540/05.

SWITCHGEAR, FUSES AND FITTINGS: L. A. WILLIAMSON [Hand-lamp connections] 3,836/09; SIEMENS BROTHERS & CO., LTD., and B. C. PAYNE [Slow motion for starters, &c.] 4,317/09.

MISCELLANEOUS: M. ARNDT [Electrically-worked engine indicator] 4,252/10.

Procedure Regarding Enemy Applications

Some slight changes have been made in the procedure under the temporary rules issued by the Patent Office in August last. It was then laid down that during the continuance of the war no patent would be sealed and no registration of a trade-mark or design would be granted to subjects of any State at war with his Majesty. The procedure is now defined by the following amended section:—"As regards applications for patents, designs, or trade-marks, no distinction will in the first place be drawn between those made by such subjects and those made by other persons. All proceedings thereunder will be carried on as usual down to and including acceptance; but in the case of applications by such subjects all proceedings thereon subsequent to acceptance (except such proceedings and matters as are mentioned in Section 9 of the Patents and Designs Act, 1907) will be suspended until otherwise directed. The suspension of proceedings upon applications by such subjects will only be recalled or discharged upon proper terms, including, if thought fit, the release of the applicant of the privileges and rights which he would otherwise have under Section 10 of the Patents and Designs Act, 1907." (The Section 9 referred to requires that the acceptance be advertised and the specification open to public inspection. Section 10 provides that on acceptance the application shall have all the rights as if the patent had been sealed, except that he is not entitled to institute proceedings for infringement until the patent has actually been granted.) It is further laid down that opposition by subjects of an enemy State cannot be entertained, and that proceedings in opposition to enemy patents will be suspended until the end of the war. All applications communicated from enemy subjects will be treated as if made directly by the communicator.

ELECTRIC TRACTION NOTES

An agreement is to be entered into between the Marylebone Parish Council and Edison Accumulators, Ltd., whereby the latter will take over the lease of premises occupied by the Jackson Electric Stove Co., adjacent to the generating station. All electric-vehicle charging in the borough is to be carried out through Edison Accumulators, Ltd. (electric vehicles owned by the Council may be excepted), the charge being 1d. or 2d., according to circumstances.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The King has conferred, among the Birthday Honours, a Knighthood upon Mr. W. Slingo, Engineer-in-Chief to the General Post Office. Mr. Slingo, who has been in the Post Office service since 1870, took over the post of Engineer-in-Chief in succession to Major O'Meara in March, 1912. In the early days Mr. Slingo was closely identified with technical training in the Post Office service, and from 1876 to 1898 was identified with the Telegraphic School of Science. In 1898 he was transferred to the Engineering Department, and in 1910 took charge of the inventory work in connection with the transfer of the National Telephone Co.'s business to the Post Office, and subsequently took a leading part in the arbitration proceedings for determining the price to be paid for the Company's undertaking.

Another member of the telegraphic and telephonic profession is included in the Birthday Honours List, viz., Mr. William Maxwell, Director-General, Post and Telegraphs in India, who has been made K.C.I.E.

The Poulsen Wireless Telegraph Co. has been registered with a capital of £450,000. The objects, of course, are to work the Poulsen wireless telegraph system and to adopt an agreement with the British & Overseas Engineering Syndicate. The first directors are Sir Leigh Hoskyns, Bart., A. Davidson, S. F. St. J. Steadman, L. S. Robertson, V. Gandil, and C. Hage (Copenhagen). Registered office, 4 Suffolk Street, Pall Mall East, S.W.

Under the Merchant Shipping (Convention) Act of 1914 all British ships carrying fifty or more persons were to be fitted with a wireless telegraph installation by January 1st, 1916. Similarly, foreign ships entering British ports were required to be provided with wireless equipments, but presumably in view of the present conditions the Board of Trade has decided to take the necessary steps to postpone the coming into operation of these provisions.

ELECTRIC LIGHT SWITCHING COMPETITION

OUR readers will remember the particulars and examination papers of the Switching Competition published in ELECTRICAL ENGINEERING last November. They may also remember that overseas competitors, excepting, of course, those in Ireland, were given till June 1st last to send in their papers. The complete overseas results are as follows:—

Advanced Grade Certificate and Prize.—R. Drilhon, Pau (B.P.), France. (Previously announced.)

Intermediate Grade (Certificates).—H. Christall, London, Ontario, Canada; S. N. Ghosh, Calcutta.

Preliminary Grade (Certificates).—E. H. Asavaid, Bombay; P. N. Chinoy, Bombay; J. J. Irani, Poona; and J. Rustomji, Bombay.

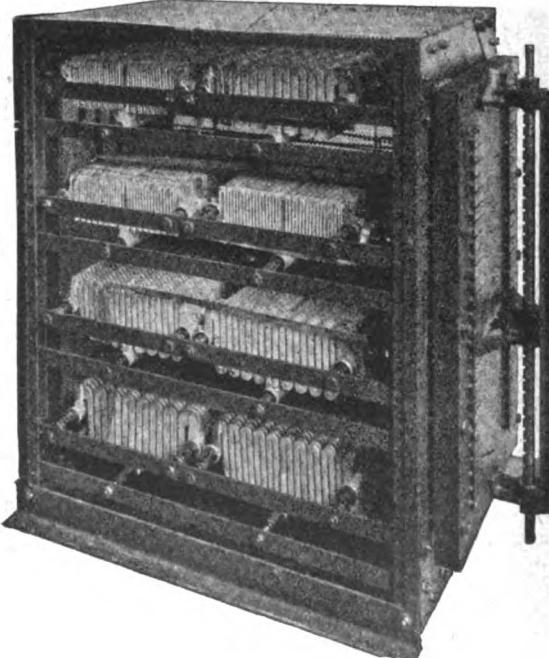

THE ADNIL ELECTRIC CO.'S POSITION

A N interesting case was heard by a Court of Appeal last week, in which the Adnil Electric Co., Ltd., sued the British Traders' Association for payment of monies collected by the latter on behalf of the Company. It appears that before the war the British Traders' Association was requested by the Adnil Electric Co. to collect certain sums of money due from various debtors. After the war broke out, however, the British Traders' Association refused to pay over the sums so collected, on the ground that the Adnil Electric Co., Ltd. (which, of course, is owned by the Bergmann Electrical Works, Berlin), was an alien enemy. The decision, however, in the case of the Continental Tyre Co.

set this point at rest, it being then decided that a company registered in Great Britain, although the share capital might be in the hands of alien enemies, had a right to sue in British courts. Whilst the decision in this case was pending, however, it came to the knowledge of the British Traders' Association that Messrs. Marples & Leach, who were managers of the Adnil Electric Co., were trading on their own account at the same address and with the same staff. This action on the part of Messrs. Marples & Leach, it is now argued, in effect breaks their contract with the Adnil Electric Co., and that consequently Messrs. Marples & Leach, as the representatives of the Adnil Electric Co., could no longer sue on behalf of that Company. The position as put by the British Traders' Association is that Messrs. Marples & Leach, having in effect dissociated themselves from the Adnil Electric Co., and the Adnil Electric Co.'s directors all being resident in Germany, that Company for the present is not in a position to sue, and that therefore the sums collected on behalf of it must remain in the hands of the Association until the end of the war. The argument against paying it over now to Messrs. Marples & Leach is that these gentlemen will use it for the purposes of their own independent business, and that the British Traders' Association might later on, when the Adnil Co. is in a position to sue, be compelled to pay the money again. The Court dismissed the appeal by a majority of two to one, and held that Messrs. Marples & Leach have no authority to sue on behalf of the Adnil Co. Lords Justices Swinfen Eady and Bankes agreed on this, Lord Justice Phillimore dissenting. Much turned upon a letter written in December to the Tyler Apparatus Co., in which Messrs. Marples & Leach stated that they intended to carry on business on their own account, and that no money received by them and in respect of that business would go to the enemy shareholders of the Adnil Co. Counsel for Marples & Leach, in order to establish his case that the agreement with the Adnil Co. had not been broken, said that letter was untrue, and that he could not justify it. The Court, however, held that this letter, in the peculiar circumstances, cancelled the agreement between the Adnil Co. and Marples & Leach, and that therefore the latter had no authority to sue on behalf of the Company. The action also involved other defendants in respect of goods supplied by the Adnil Co.

ALTERNATOR FIELD REGULATORS

FROM time to time we have illustrated several examples of alternator field regulators which are standardised by the General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, E.C.). These regulators have been of both the circular and the rectangular pattern, with wire, grid, or strip resistances. A further design is shown in the

RECTANGULAR TYPE ALTERNATOR FIELD REGULATOR, WITH GRID RESISTANCES.

accompanying illustration, and was constructed for a large firm of turbo-alternator manufacturers. The "Witton" standard rectangular face-plate construction is used, together with standard grid resistances mounted on a strong angle-iron framework. The strength and compactness of the unit can be readily appreciated.

"WITTON" MULTIPLE SWITCH STARTERS

THE face-plate type of starter serves well for starting small continuous-current motors, but for large motors they are not so suitable on account of the heavier starting currents to be controlled. For this class of work the multiple lever starter has been employed, but this type of starter also has the drawback that breaking the current on the contacts themselves may occur and result in damage through arcing and rapid deterioration of the contacts. The General

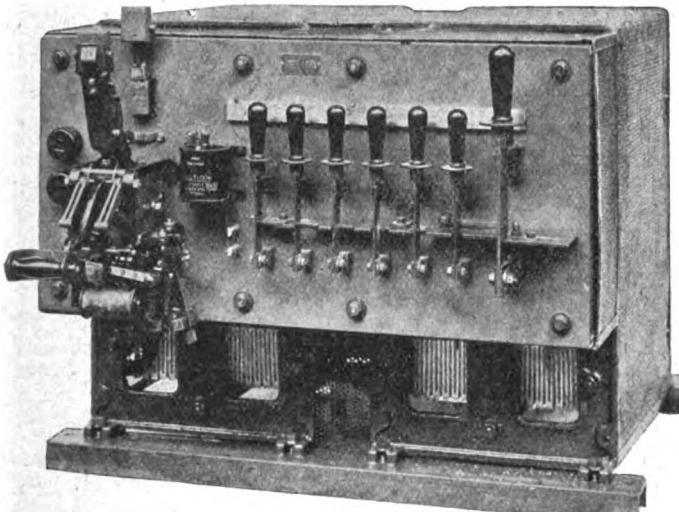

FIG. 1.—“WITTON” MULTIPLE SWITCH STARTER FOR CONTROLLING 100-H.P. C.C. MOTOR.

Electric Co., Ltd. (Witton, and 67 Queen Victoria Street, London, E.C.), has developed a type of starter which avoids this defect. The current is broken by a specially designed circuit-breaker, while the separate knife switch cut out the sections of the resistance in the ordinary way, and are interlocked electrically with the circuit-breaker. In starting up a motor controlled by a “Witton” multiple switch starter, the circuit-breaker is first closed, and the switch cutting out the first step in the resistance is then inserted. But should an attempt be made to insert either the switch that short circuits the resistance or an intermediate switch on the

mechanism and prevents the breaker being closed. Not only is the “Witton” multiple switch starter a mistake-proof device, with a special device for breaking the current, thus preserving the ordinary current carrying contacts from the effects of arcs, but it has been found to be cheaper to construct than other forms of multiple lever starter. Fig. 1 shows a “Witton” multiple switch starter for controlling a 100-h.p. motor, together with the necessary resistance and circuit-breaker, while a view of a similar device controlling a 300-h.p. “Witton” rolling mill motor is shown in Fig. 2. In the latter case it will be observed that the switches are provided with a suitable cover.

CATALOGUES, PAMPHLETS, &c., RECEIVED

LOCKING LAMP-HOLDERS.—A leaflet from Mr. C. H. Jeffcoat (18 Ranelagh Gardens, Hammersmith, W.) gives prices and particulars of the locking lamp-holder described in ELECTRICAL ENGINEERING (Feb. 11th, p. 62).

ELECTRICAL SUPPLIES.—New leaflets from Krupka & Jacoby, Ltd. (39 Victoria Street, S.W.), give particulars of switch lampholders, pocket lamps, and table fans.

ACCESSORIES.—A new list from Donovan & Co. (47 Cornwall Street, Birmingham) gives prices of a wide range of electrical accessories.

HEATING AND COOKING APPARATUS.—A leaflet from Haylock & Haslett (63 Queen Victoria Street, E.C.) calls attention to the “El Grilstovo” electric cooker for grilling, frying, boiling, toasting, &c., to which a small oven can be added for baking and roasting purposes. A breakfast grill and an immersion heater are also described on a postcard being issued by the firm.

MEASURING INSTRUMENTS, &c.—A very conveniently arranged new catalogue of measuring instruments, circuit-breakers, cut-outs, &c., has been issued by the Record Electrical Co., Ltd. (Broadheath, Manchester, and Caxton House, Westminster, S.W.). A large number of patterns of instruments are listed, and the list is not only provided with a thumb index for rapid reference to any particular portion, but a tab at the back makes it readily distinguishable from other lists when filed.

AIR-PUMPS, &c.—An illustrated booklet from the Worthington Pump Co. (India House, Kingsway, W.C.) describes a form of rotary dry vacuum pump or blower which the Company has recently introduced under the name of the “Roto-drum Pump.” This works on the principle of the rotating eccentric drum fitted with sliding plate or piston, which opens and closes by the rotation of the drum. By this special design friction is reduced to a minimum, and the pumps are capable of running at high speeds direct-coupled to electric motors.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in “Electrical Engineering.”

CONDUIT WIRING, &c.—A booklet entitled “Wiring for Electric Light and Power” is being issued by Simplex Conduits, Ltd. (116 Charing Cross Road, W.C.), putting forward in well-chosen words the advantages of the Simplex conduit wiring system. The Company has also prepared an attractive series of eight blotting cards, on the backs of which attention is called to details in connection with their conduit system and other lighting fittings and accessories in which they specialise.

WATER STERILISER.—A leaflet from Ozonair, Ltd. (96 Victoria Street, S.W.), gives particulars of a small water steriliser, containing an electric ozone producer, for domestic purposes. The apparatus is quite self-contained, and is put in action simply by turning the tap to draw the water.

ELECTRIC FANS.—A leaflet from J. & W. B. Smith (15-23 Farrington Road, E.C.) gives prices and particulars of several patterns of ceiling, porthole, desk, and bracket fans for continuous and for alternating current.

IRONS AND HEATING APPARATUS.—A new list from the Dowsing Radiant Heat Co., Ltd. (39 and 40 York Place, Baker Street, W.), gives particulars of “Hot Point” electric irons and other heating appliances for domestic and industrial use, most of which are improved patterns of the types of apparatus formerly made by Eastman & Warne. The items include such special applications of electrical heating as collar, cuff, and goffering iron rollers, special heaters for singeing whitewash brushes, hot irons for cutting balata belting, singeing operations in the manufacture of velvet, branders and stamping dies of all descriptions. In a few cases prices have had to be increased owing to the rising cost of raw materials, but in the case of standard articles, now made in larger quantities, the previous low prices have been maintained.

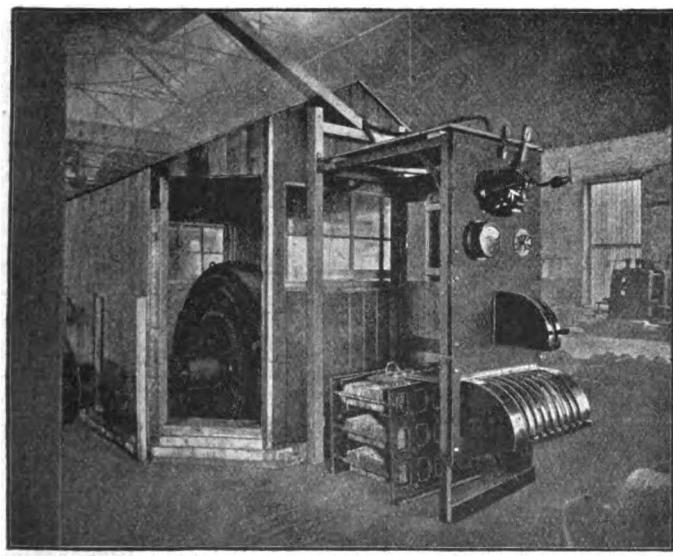

FIG. 2.—“WITTON” MULTIPLE SWITCH STARTER CONTROLLING 300-H.P. ROLLING MILL MOTOR.

starter, the attempt is frustrated by an interlocking bar. This bar is automatically moved along by the switches as they successively close, and precludes the closing of any of the other switches out of their proper sequence. Further, should the circuit-breaker trip due to an overload on the motor and an attempt be made to replace it—which would mean short-circuiting the supply—a special trip coil on the circuit-breaker is energised through contacts which are closed when any or all of the switches on the starter are closed. The action of this trip coil locks the circuit-breaker

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Aldershot.—A Local Government Board inquiry is to be held concerning a loan of £8,500 for new plant.

Aylesbury.—Metallic filament lamps from 60 to 400 watts. Town Clerk. June 14th.

Batley.—The L.G.B. has sanctioned a loan of £3,391 for cable extensions.

Burnley.—In view of the L.G.B. policy not to sanction loans for ordinary cables and services, the Electricity Committee has authorised the cost of small cables to connect up new consumers to be met out of revenue.

Manchester.—A 50-kw. steam-driven dynamo is required at the Cottage Homes, Styal, Manchester. Consulting Engineer, Mr. F. W. Page, 14 St. Ann's Square, Manchester. June 16th.

Middlesbrough.—A loan has been sanctioned for expenditure in connection with supply to firms working on Government contracts. A sum required for dealing with ordinary consumers has been refused.

New Zealand.—The Wellington City Council requires two boosters, two switch-panels and instruments. Further particulars at 73 Basinghall Street, E.C.

Stretford.—Cable extensions.

Turton.—Cable extensions and conversion of street lamps from gas to electricity.

Wigan.—Two water-tube boilers and mechanical stokers. Borough Electrical Engineer. June 21st. (See advertisement on another page.)

Wiring

Atherton.—Church of St. John the Baptist.

Belfast.—Guardian offices and board-room. Consulting Engineers, Young & Mackenzie, Clerk to Guardians. June 15th.

Bingley.—Private residence. Architect, F. Atkinson, Penny Bank Chambers, Shipley.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Blackburn.—Warehouses for Star Paper Mill.

Manchester.—Warehouse, Mosley Street. Architects, Pye & Bennett.—Warehouse, Major Street. Architects, J. Swarbrick & Son.

Miscellaneous

Australia.—The Sydney Corporation requires a supply of electric meters. Further particulars at 73 Basinghall Street, E.C. July 19th.

Falkirk.—The Guardians require twelve months' supply of electric lamps. June 16th.

Hull.—The Guardians require six months' supply of electrical goods. Clerk, St. Mary's Chambers. June 19th.

London: *L.C.C.*—The Asylums and Mental Deficiency Committee require four months' supply of electrical sundries and lamps. Clerk, 6 Waterloo Place, S.W. June 14th.

New Zealand.—The Christchurch City Council requires a two years' supply of house service meters. Further particulars at 73 Basinghall Street, E.C.

York.—The Tramways Committee proposed to borrow £30,681 for tramway purposes.

British Industries Fair.—In view of representations made by the exhibitors and buyers at the British Industries Fair, which was held in the Royal Agricultural Hall recently, the Board of Trade has decided to hold another fair in London early next year.

Prohibited Exports.—Included in the new list of articles, the exportation of which from the United Kingdom is prohibited, are tungsten filaments for electric lamps.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Leigh (Lancs.).—The following tenders have been accepted:—Rotary converter, Bruce Peebles & Co.; switch-gear, Switchgear & Cowans; water-tube boiler, Stirling Boiler Co.; mechanical stoker, Underfeed Stoker Co.

APPOINTMENTS AND PERSONAL NOTES

Mr. Percy Taylor, Assistant Electrical Engineer, Darwen, who enlisted in the Mechanical Transport service a few weeks ago, has been appointed mechanical staff-sergeant.

Mr. J. C. Whiteley, Assistant Manager to the Chatham and District Light Railways, has been appointed Tramway Manager at South Shields at a salary of £300 per annum.

The Newport Electricity & Tramways Committee recommends that a bonus of £100 each be given to the General Manager of the Department and the Borough Electrical Engineer.

Mr. F. C. Leese and Mr. A. E. Leese, sons of Alderman H. Leese, Stoke-on-Trent, who resigned their positions in the Stoke Electricity Department as mains superintendent of the southern area and switchboard attendant respectively, have each been presented with a gladstone bag by their colleagues. These resignations took place after a discussion in the Corporation a short time ago, in which some strong remarks were made against relatives of councillors being employed by the Corporation.

Mr. T. Duesbury, Borough Electrical Engineer at Sutton Coldfield, has resigned in order to join H.M. Forces. In a letter tendering his resignation, Mr. Duesbury said that "there are almost as many single men of military age sheltering under the municipal umbrella as under the Government umbrella."

We are pleased to note that Lieut. E. G. Boissier, R.N.D. "Howe" Battalion, and late mains superintendent in the Derby Corporation Electricity Department, has been granted the Distinguished Service Cross. Lieut. Boissier has seen much hard fighting at the Dardanelles.

Mr. R. N. Mayne, Borough Electrical Engineer at Redditch, has received a commission in H.M. Forces. The Electric Supply Committee, whilst recognising Mr. Mayne's patriotism, has appealed to him to reconsider his decision on the ground that his presence in the town is equally important, as the electricity undertaking is supplying large quantities of power to firms manufacturing munitions of war.

The Bury Corporation has decided to increase the salary of the Borough Electrical Engineer, Mr. S. J. Watson, from £550 to £650 per annum. There was strong opposition, but the increase was finally sanctioned by 20 votes to 11.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £92 to £93 (last week, £89 10s. to £90 10s.).

Siemens' Lamp Department.—The Sales and Advertising Departments of Siemens Brothers Dynamo Works, Ltd., Incandescent Lamp and Fittings Department, Dalston, have now been transferred to 39 Upper Thames Street, E.C., from which address both the lamp and supplies business will be controlled. The rearrangement is due to the increasing turnover of Wotan and Tantalum lamps. Although large stores were recently acquired at Shacklewell Lane, the introduction of new types of lamps, including gas-filled lamps, demanded further extensions. The Dalston Works will now therefore be devoted solely to lamp manufacture and the output correspondingly increased. All correspondence relating to Dalston material should be addressed to 39 Upper Thames Street, E.C.

LOCAL NOTES

Aylesbury: *Opening of Electricity Works.*—The Council's electric lighting station was formally opened last week. The main contractors for the plant are Messrs. Willans & Robinson, the generators being supplied by the Electric Construction Co., and the switchboard by Johnson & Phillips, who are also the contractors for the whole of the underground cable work and distribution system.

Barrow-in-Furness: *New Plant.*—The Town Council paid a visit of inspection to the electricity works last week on the occasion of the starting up of a new 2,000-kw. turbo-alternator, which, together with the necessary auxiliary plant, has cost £13,000. It is anticipated that ere long it may be essential to replace some of the plant installed at the commencement of the undertaking by more modern machinery.

Dover: *Plant Extensions Postponed.*—The L.G.B. is not disposed to sanction the loan of £6,000 for a new generating set, notwithstanding that this is required in a great measure for naval and military needs. It is suggested to the Corporation that a smaller generating set might be installed in order to reduce the capital expenditure necessary. The Electricity Committee, however, does not regard this as a business proposition, and have decided to hold the whole matter over until a later period.

Dublin: *Electricity Charges.*—The Electricity Committee now definitely recommends that the charge for lighting be increased by 1d., and the power rate by 1d. per unit. This, it is anticipated, will leave a small deficit of £280 on the year's working. On the basis of existing charges it is calculated that the deficit would amount to no less than £21,334.

Grimsby: *Reduced Electricity Revenue.*—The electricity accounts for the last year show a net profit of £721, after meeting expenditure on works of a capital nature out of revenue to the extent of £1,642. Owing to loss in revenue the profits are about £2,000 less than were anticipated.

London: St. Pancras: *Repayment Periods.*—For a long time correspondence has been carried on between the Finance Committee of the L.C.C. and the Electricity Committee regarding the conditions upon which a loan of £15,000 for a 5,000-kw. turbo-alternator should be granted. The two parties are agreed as to fifteen years being the period for this particular item, but the L.C.C. also desire that the Borough Council shall reduce the outstanding period on plant and machinery for which a term of forty-two years has been granted, to one-half, or not exceeding fifteen years. This condition is not to apply to 2,360 kw. of plant of this character which is required for daily use. The Borough Council all along has resisted any reduction in the periods of the older plant, and has again replied that it must adhere to its previous decision in this respect.

Loan for Boilers.—The Electricity Committee recommends that H.M. Treasury be asked to sanction the borrowing of £22,580 for boilers at the King's Road electricity station on the ground that this additional boiler accommodation is very necessary to the undertaking, and that the contract was entered into prior to the war.

Manchester: *The Barton Power Station.*—The Manchester Ratepayers' Association has communicated with the Chancellor of the Exchequer, giving reasons why the Treasury should refuse sanction at the present time to the carrying out of the extension scheme of the Electricity Committee, as reported in our issue of May 27th, p. 230. The L.G.B. Inspector at the inquiry stated that he was instructed to deal with the application immediately. It is claimed that a suspension of the Barton power-house scheme would not entail a severe strain on the undertaking in meeting new applications for supply.

West Bromwich: *Increased Charges.*—Hitherto the increase in electricity charges in most parts of the country has not exceeded 10 per cent., and in some cases it has been only 7½ per cent. In a special report to the Town Council, however, the Electricity Committee recommends that the increase at West Bromwich shall be 20 per cent., in view of the increased cost of materials and wages.

West Saltney: *Electric Lighting Scheme.*—A L.G.B. inquiry was held last week concerning an electric lighting scheme for the district. Mr. J. W. Speight, the Consulting Engineer, stated that the Council had decided to accept the tender of Sandycroft, Ltd., at £5,740, subject to the necessary loan being granted. The district includes Queen's Ferry, and it is anticipated that if the scheme can be put into

operation quickly the Government factory there will take power and lighting. It was also pointed out that in other parts of the district candles and paraffin oil lamps are used for business premises.

"**The Teaching of Electric-Light Switching.**"—A. P. Lundberg and Sons write us as follows:—"We should be obliged if you will allow us to correct a slight misapprehension that may arise from your notice of our pamphlet on the above subject in your last issue. You speak of the "Opinions of some teachers at the end." As a matter of fact, the Opinions are both at the beginning and the end, and include some from very well-known professors, and number thirty-five in all.

Newcastle Local Section of the Institution of Electrical Engineers.—The annual report of the section records the holding of nine meetings at Newcastle, eight meetings of the Tees-side sub-section, and five students' meetings. The present membership of all classes totals 261, notwithstanding a decrease, especially in the students' class, owing to the war. The following officers and committee have been elected for the next session:—Chairman, P. V. Hunter; Vice-Chairmen, H. W. Clothier and A. H. Marshall; Past Chairmen, W. C. Mountain and C. Vernier; Committee, Power Supply Undertakings, F. Fawssett, G. L. Porter, and W. F. T. Pinkney; Corporations, H. S. Ellis and C. Turnbull; Manufacturers, W. G. Guns, T. Carter, and M. G. S. Swallow; Consulting Engineers, C. S. Vesey Brown, R. W. Gregory, and J. R. Beard; Railway Representatives, G. L. Drury and H. Henderson; Scholastic Profession, Dr. W. M. Thornton and F. O. Hunt; Shipyards, Post Office, and Contractors, A. P. Pyne, J. R. M. Elliott, and W. Cross; Hon. Treasurer, C. Vernier; Hon. Secretary, J. R. Andrews; Hon. Auditors, J. H. Holmes and G. Stoney, F.R.S.

SUMMARY

A DEPUTATION representing the gas and electrical industries waited upon a meeting of members of Parliament on June 9th and discussed the difficulties arising from the shortage of coal supplies.—In the House of Commons last week, the President of the Board of Trade hinted that the Government will, if necessary, bring force to bear to prevent exploitation of coal by the mine-owners. A Government Committee has reported that but for the avoidable absence from work during the past seven months on the part of those engaged in the coal trade, the output could have been increased by some 13 million tons (p. 252).

THE Incorporated Municipal Electrical Association meets to-day and to-morrow in London under the presidency of Mr. A. C. Cramb, the Senior Vice-President. The President, Major H. Richardson, is with the Army (p. 253).

ILLUSTRATED descriptions are given of the cars taking part in the electric vehicle parade to be held this afternoon in connection with the meeting (p. 253).

A NEW British-made electric commercial vehicle is described in an illustrated article ((p. 257).

THE colliery and a new power station, about 80 miles from Berlin, which were to have supplied the Berlin Electricity Works with current, are now to be utilised for supplying an enormous amount of electric power for the "fixation" of nitrogen in a chemical fertiliser works. It is just conceivable, however, that the production of nitrates on this large scale may be primarily for the manufacture of explosives. In consequence of this decision, whatever may be the real reason for it, the municipality of Berlin is taking over the electricity undertaking in that city on October 1st. About £6,500,000 is to be paid for the undertaking (p. 258).

A SCHEME for linking-up the Hammersmith, Fulham, and Battersea electricity undertakings is under consideration. If it is carried into effect it is hoped to relieve the Battersea Council of considerable immediate capital expenditure in meeting the demands upon its mains (p. 258).

THE reversal of single-phase motors is discussed in our "Questions and Answers" columns (p. 259).

AN illustrated description is given of an electrically-equipped shoe factory. (p. 260).

AMONG the subjects of the specifications published by the Patent Office last Thursday were connection boxes, electric vehicle control, conduit fittings, lamp locks, and protective resistances. A telephone transmitter patent is opposed. Patents dealing with electric drills, fuses for explosives and the driving of centrifugal separators expire this week after a full life of fourteen years (p. 261).

A RECENT design of porcelain-handle fuse is illustrated on p. 262.

A 5,000-kw. turbo-alternator is required at Salford; a D.C. generator at Melbourne; cable at West Hartlepool, and electrical supplies at Exeter, West Ham, Brighton, and Bristol (p. 262).

A 25 per cent. increase in the charges for lighting and power is to be made at Kirkcaldy.—The units sold last year at Barrow increased by 1½ million over the previous year.—Half-watt lamps are to be used for street lighting at Ashton-under-Lyne.—A 10 per cent. increase for lighting and power is to be made at Taunton, but no increase for heating and cooking.—The net profit at Lincoln last year was £3,163, against £2,715 in the previous twelve months (p. 263).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

ON the suggestion of General Sir O'More Creagh, V.C., G.C.B., G.C.S.I., an engineer volunteer corps has been raised from members of the engineering profession who are either above military age, or who being of military age are prevented by some good reason from serving in the Regular Forces.

The objects of the Corps are:—

1. To train men of military age and to make them useful Royal Engineer recruits if and when they are able to enlist.

2. To furnish Engineer units to assist in the completion of the Volunteer organisation.

3. To organise the Corps so that the maximum advantage may be taken of the specialised engineering skill of its members at the earliest possible moment.

Drill takes place through the kindness of Colonel Le Rossignol and the officers of the London Electrical Engineers Corps at the Drill Hall, 46 Regency Street, Westminster. The training will be similar to that of the London Electrical Engineer Corps.

Although the first drill only took place on the 2nd inst., already 130 members are enrolled. Membership is not restricted to members of the Engineering Institutions, and application should be made to the Commandant, Lt.-Col. C. B. Clay, V.D., at Marconi House, Strand, W.C.

COAL SUPPLIES

FOLLOWING the deputation of the National Conference on Coal Supplies to Gas and Electricity Undertakings to the Coal Exports Control Committee (ELECTRICAL ENGINEERING, May 27th, p. 224), a deputation representing the gas and electrical industries attended at the House of Commons on Wednesday, June 9th, and laid before a meeting consisting of about two hundred Members of Parliament the serious difficulties in which they find themselves owing to shortage of coal. Lord Claud Hamilton presided. The speakers were Sir Corbet Woodall, Past President of the Institution of Gas Engineers, and Governor of the Gas Light & Coke Co.; Sir John Snell, President of the Institution of Electrical Engineers; Alderman Kay, Chairman of the Gas Committee of the Manchester Corporation; Mr. Frank Bailey, Joint Managing Director of the City of London Electric Lighting Co.; Dr. Charles Carpenter, Chairman of the South Metropolitan Gas Co.; Bailie Irwin, Convener of the Gas Committee of the Glasgow Corporation; and Bailie W. B. Smith, Convener of the Electricity Committee of the Glasgow Corporation.

Attention was drawn by the various speakers to the seriousness of the shortage of coal. This shortage was due to several causes, among which was mentioned particularly the enlistment in the Army and Navy of a large number of miners and the consequent limitation of output. To meet this, further and greater effort was necessary on the part of the miners and the coalowners, which might be stimulated by some limitation of the prices to be charged for coal. Restriction of export of coal was also mentioned. The question of the all-round necessity and utility of gas and electricity was urged at length. It was pointed out that not only were gas and electricity used for lighting, cooking, heating, and power purposes by all classes, but they were also used in a vast number of industries such as engineering works, shipyards, and chemical and textile concerns in all the great industrial centres, where Government work is proceeding night and day, and where it is absolutely essential that the necessary motive power should be continuously available. It was also explained that a number of gas and electricity undertakings had so adapted their plant that they were producing materials of vital importance to the Government, and, furthermore, that the residuals resulting from the manufacture of gas from coal, such as coke, tar, and ammonia, were necessary to a great variety of important industries; also that a considerable supply of high explosives was being obtained from the by-products resulting from the distillation of coal by gas undertakings. In Germany the Government were using every means in their power to restrict the use of coal except in closed vessels, such as retorts and ovens, so as to increase as much as possible the output of the valuable by-products above referred to. Similar action in the United Kingdom would be highly valuable.

In connection with electrical undertakings, the fact was recalled that electricity had reached such a point of efficiency in the use of coal that it was of material advantage in saving the greatest asset of the nation at this time, and that if the electrical supply had to be curtailed or stopped there would be no electrical searchlights, and, in addition, the food supply of London and the country would be in danger owing to the stoppage of the refrigerating plant in the cold-storage warehouses.

Generally speaking, it was an absolute impossibility to take in sufficient coal during the winter for the winter's requirements, and therefore a large stock had to be accumulated during the summer months when the demand was not so heavy. This year it had, so far, been impossible to carry out this system, and if the stocks were not made up by the middle of October the public undertakings would be unable to continue their supply through the coming winter.

Various means of improving matters were suggested, amongst which were mentioned a limitation of further recruiting of miners, a suspension of the operation of the Eight Hours Day Act in respect of collieries in order to increase the actual output of coal, the fixing of a maximum rate of freight for all interned vessels, further facilities generally for the transport of coal, and a continued limitation of the export of coal. Finally, it was urged that if Members representing mining districts could induce their constituents to work full time, a large part of the difficulty of shortage would be overcome.

The Members of Parliament discussed the suggestions put forward at a further meeting on Tuesday. The meeting

generally was in sympathy with these suggestions, and it was decided to appoint a Committee of twelve to interview Mr. Runciman, President of the Board of Trade. This Committee will consist of representatives, in equal proportions, of coal-owners, miners, shipowners, and large consumers, and it is hoped, as a consequence of the interview with the President of the Board of Trade, to be able to make specific recommendations to a further conference between the Members of Parliament and those concerned next week.

In the course of a discussion on the cost of living in the House of Commons on Thursday, Mr. Runciman, President of the Board of Trade, speaking on the question of coal supplies, said there was no commodity the rise in the price of which had given more anxiety than coal. Unlike certain other articles, the price of coal was very little dependent on the world's productions, and it was possible to deal with the situation compulsorily if they could not arrive at an agreement with the merchants and coal owners which was satisfactory to the consumers. It so happened that the small colliers usually engaged in the coal trade in the North were especially suitable for Admiralty purposes, and a great number had been commandeered, whilst the interned ships which were put into the trade in their place were not suitable. Furthermore, the whole of the traffic had been impeded by Admiralty precautions, and a voyage which would ordinarily take a third of a fortnight now took a whole fortnight. So much for the coal-carrying trade. As to coal merchants, it was fair to say that in some respects their expenses were greatly enhanced by the war, but the increased handling expenses were by no means sufficient to explain the enormous rise in prices. The Government, however, had been able to arrange that profits should be strictly limited, and this limitation should keep the price at a fairly steady level. They were therefore thrown back on the coal owners. The chief extra cost, from their point of view, was miners' wages, and the mine-owners put this at 1s. 6d. per ton, but that undoubtedly was a grossly exaggerated figure. The real estimate was much nearer pence than shillings, and it remained a fact that the present pithead price of coal was far in excess of the figure which the expenses of getting coal could justify. The owners argued that the industry was a highly speculative one, and that whilst they made large profits in some years they made very little in others. Communications had taken place between the Government and the owners, however, and an agreement had almost been come to with the Midland coal-owners. It was obvious that if the Government were not fairly met by agreement it would not support any exploitation, and an endeavour was being made to come to agreements which would check the violent fluctuations that were disturbing households and industry.

The report of the Committee appointed "to inquire into the conditions prevailing in the coal-mining industry with a view to promoting such organisation of work and such co-operation between employers and workmen, as, having regard to the large number of miners who are enlisting for naval and military service, will secure the necessary production of coal during the war," was issued last week. This Committee finds that from returns representing 89 per cent. of the total labour employed in coal mines, there was a decrease of 13½ per cent., or 134,186 persons between July, 1914, and February, 1915, and that over the seven months from August, 1914, to February, 1915, there has been an average fall in output of 3,044,529 tons, or 13½ per cent. It has also been found that the absence from work by all classes of mine workers for the seven months preceding the war and the seven months succeeding the war has been practically identical, viz., 10·7 per cent. and 9·8 per cent. respectively, and the conclusion has been arrived at that fully 48 per cent. of this is avoidable absence. The absenteeism, taking the coal-getters only, is very much higher, and if there were no avoidable absence the output would be increased to the extent of between 13 and 14 million tons. The Committee express the opinion that the case has only to be put before the miners in order to secure a great response, and it is proposed that the attention of the Miners' Federation of Great Britain be called to the matter. It is further suggested that owners and workmen should agree to suspend, according to the district conditions, the Eight Hours Act, and that the time appears to have arrived when very full consideration should be given to the question of whether further recruiting among miners should be encouraged. Where the restriction of the export of coal to neutral countries is found to be advisable, it is suggested that special consideration should be given to those mining districts which, to a large extent, depend on export for the existence of their collieries. Another suggestion made by the Committee is that the importance of economy in the use of coal should be brought before the public, and economies in public and private lighting, whether by gas or electricity, and the manufacture of luxuries which require coal, are recommended.

THE I.M.E.A. MEETING

THE Incorporated Municipal Electrical Association will meet in London at the Institution of Electrical Engineers' Building, Victoria Embankment, to-day and to-morrow. The meeting this year is not a social one, and visitors are not invited to attend, but it is intended to devote to-day to serious discussions on the "point five" tariff and the use of electric vehicles in municipal service, and to-morrow to the usual business of the annual general meeting. This afternoon, at five o'clock, there will be a parade of electrical vehicles on the Embankment, and this evening a meeting of the "Point Fives" Association at Tricity House, Oxford Street. At this latter meeting, we are informed that members of the I.M.E.A. who are not "Point Fives," and visitors connected with the electric cooking and heating

industry, will also be admitted. The "Point Fives" meeting will be under the chairmanship of Mr. S. E. Fedden, of Sheffield, and it is to be expected that the main subject discussed will be the effect of the war on the consumption under the "point-five" tariff. The I.M.E.A. meeting will be under the presidency of Mr. A. C. Cramb (Borough Electrical Engineer,

MR. A. C. CRAMB.
(The Acting President.).

Croydon), who, as senior Vice-President, is Acting President for the year. His portrait appears above.

Major H. Richardson, the President, is on active service.

We shall publish a full report of the meeting in our next issue.

The complete programme is as follows:—

TO-DAY (THURSDAY).

10 a.m.—To receive and discuss a report prepared by Mr. A. S. Blackman (Chief Electrical Engineer, Sunderland), and Mr. T. Roles (Chief Electrical Engineer, Bradford), on behalf of the "Point Five" Association, on "The Practical Result of the Point Five Tariff." [This meeting will be restricted to Members and Official Delegates of Local Authorities.]

1 p.m.—Interval.

2.30 p.m.—To receive and discuss a report prepared by Mr. Frank Ayton (Chief Electrical Engineer, Ipswich), Hon. Secretary of the Electric Vehicle Committee of the I.M.E.A., on "The use of Electric Vehicles in Municipal Service." [This meeting will be restricted to Members, Official Delegates of Local Authorities, and co-opted Members of the Electric Vehicle Committee.]

5 p.m.—Parade and demonstration of Electric Vehicles on the Embankment.

7 p.m.—A meeting of the "Point Fives" will be held at Tricity House, Oxford Street, W.

TO-MORROW (FRIDAY).

9.30 a.m.—Council Meeting.

10 a.m.—Annual General Meeting. [This meeting will be restricted to Members and Official Delegates of Local Authorities. Corporation Delegates, other than members, are not entitled to vote.]

AGENDA.

- (1) Annual Report of the Council.
- (2) Balance Sheet and Election of Auditors.
- (3) Scrutineers' Report on the ballot for Officers and Council for 1915-16.
- (4) Place of Meeting for Convention, 1916.
- (5) Other competent business.

1 p.m.—Interval.

2.30 p.m.—If necessary the members will reassemble to complete any adjourned business.

The Council's headquarters are the Hotel Cecil (Strand). By the courtesy of the Municipal and County Club (Whitehall Court), members and delegates are invited to consider themselves honorary members of the club to-day and to-morrow.

THE ELECTRIC VEHICLE PARADE

THE parade and demonstration of electric vehicles which is to take place this afternoon on the Embankment in connection with Mr. F. Ayton's paper on the use of electric vehicles in municipal service, will be of interest as enabling engineers at the meeting to see practical illustrations of points dealt with in the paper. Owing, however, to industrial circumstances connected directly and indirectly with the war, it will not be possible for the parade to form a fully representative collection of types of electric vehicles made and sold in this country, nor a true indication of the progress which is being attained in their use as a result of the indefatigable labours of the Electric Vehicle Committee. Nevertheless, a few electric vehicle firms have been able to promise to send specimens of their cars, and these will be supplemented by examples of electric cars actually in municipal and commercial service, which will have the added interest due to their record of work accomplished. Through the courtesy of some of the intending exhibitors we are able to give the following notes on the vehicles which will be there. The numbers correspond to the order in which the vehicles will be stationed from left to right viewed from the steps of the Institution.

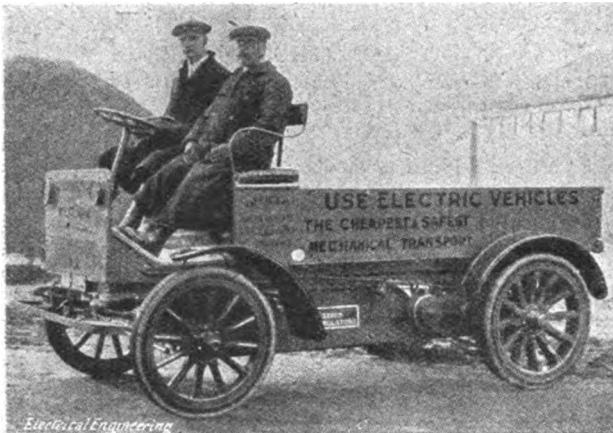

No. 1.—Walker 10-cwt. Covered Delivery Van (Harrod's, Ltd.).

This is one of the large fleet of electric cars which Harrod's, Ltd., have in regular service. It is a covered 10 cwt. van of American origin of a type not very much seen in this country, and its chief peculiarity is the method of driving the rear wheels by a single motor. This motor is in line with the axle, and its shaft carries a pinion on each end in the centre of the road wheel, which gears into a pair of large "idle" spur wheels on either side. These in turn gear into an internal rack near the rim of the wheel. This gear is all covered in by the plate webs of large driving wheels, which gives the vehicle its distinctive appearance. The battery is composed of 60 Edison cells of 220 ampere-hours capacity, and can drive the vehicle at 14 miles per hour. The control of the single motor employed is by a series parallel arrangement of the two halves of the battery contrived with a series parallel arrangement of the field coils and resistance steps.

No. 2.—20-cwt. Open-body Wagon (West Ham Corporation).

This is a good example of a vehicle which has been in active service on the general work of an electricity department. It is a one-ton chassis of one of the lighter types standardised by Edison Accumulators, Ltd. It is driven by a single motor geared to a differential counter-shaft, with a final drive to the rear wheels by side chains. The battery is composed of 60 Edison cells of the A 6 (225 ampere-hour) pattern. The car is capable of a speed of 11 to 12 miles per hour. The control

is by means of a series parallel arrangement of the two sections of the battery and resistance steps, with the addition of series parallel arrangement of the field coils of the motor. This car will be shown with an open float body, but this is removable and can be replaced by the usual type of tower and platform for working on tramway overhead lines and poles. The car is used for mains emergency work. Its full equipment also includes substantial watertight lanterns and flexibles for night work, a portable electric drill, and a small electrically driven

No. 2.—20-cwt. EDISON WAGON (WEST HAM).

centrifugal pumping outfit for emptying flooded sub-stations and similar work. This vehicle has proved of great use to the department, and since it was put into service on Nov. 21st, 1914, it has covered about 1,800 miles with a consumption of 0·5 to 0·6 kw. hour per mile. The cost of energy only without other charges therefore works out at about one ha'penny per mile.

No. 3.—“Opel” 10-cwt. Covered Delivery Van (Marylebone Borough Council).

This is another vehicle which has been employed for the purposes of an electricity department, but in this case principally for delivery work. With its swan breast dash, it is of hand-

No. 3.—OPEL DELIVERY VAN (MARYLEBONE).

some appearance, and its smoothness of running is greatly enhanced by the use of pneumatic tyres. A single motor is employed with a countershaft and side chains enclosed in a gear case, and the control is by series parallel arrangement of the battery in two sections with resistance step. The main controller handle is under the steering wheel. A Hart battery is employed. The vehicle weighs 34½ cwt., and has a speed

of about 13 miles per hour, consuming on an average 0·61 kw. hour per mile. Up to the beginning of April it had run about 5,000 miles, and the total running costs, including driver, maintenance, licences, insurance, &c., amounted to £68.

No. 4.—9-cwt. Covered Delivery Van (General Vehicle Co., Ltd.).

The General Vehicle Company, Ltd. (Imperial House, Kingsway, W.C.) will also take part in the parade, and will be represented by a full panel closed delivery van of 1,000 lb. carrying capacity. This is provided with a 44-cell nine-plate “Ironclad Exide” battery of a capacity of 133 ampere hours, giving a rated mileage of 45 miles on one charge. The battery is carried under a curved bonnet in front.

The speed of the vehicle is 15 miles an hour over good level roads; and the transmission is by single motor with double universal joint shaft and worm drive in rear axle. The worm is the latest Brown type, with steel worm and bronze worm wheel on bevel gear differential. The live rear axle is mounted on Timken roller bearings.

The car is fitted with a three-way type switch (running-

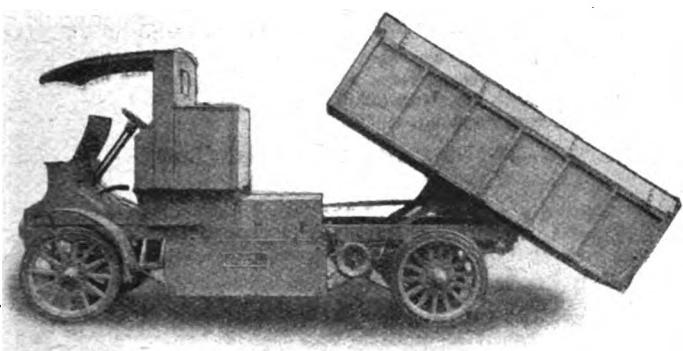

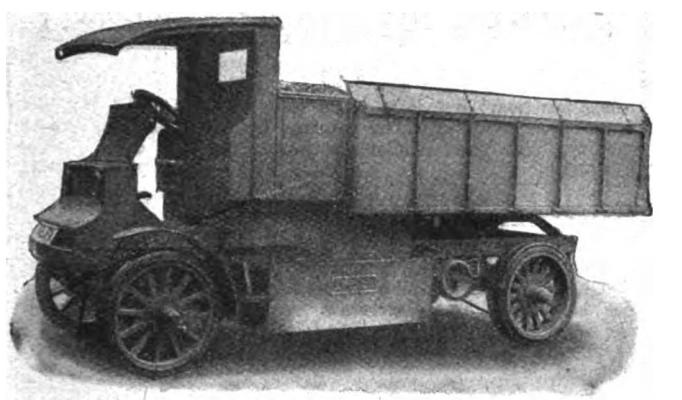

No. 4.—GENERAL VEHICLE CO.’S 9-CWT. VAN.

neutral-charging) in a sheet metal box under the driver's seat. The handle is removable only when in the neutral position, and this constitutes a safety factor when the vehicle is left by the driver. All the wiring is in rigid metal conduit, and the controller is of the “continuous-torque” type, giving four speeds ahead and two reverse. The vehicle is further equipped with the safety devices which, by the interlocking of the control gear, have the following effects:—The application of either brake immediately cuts off the power, if not already cut off by the controller. This allows the driver in an emergency to use both hands in steering the vehicle, and at the same time cut off all power and apply two brakes. Also, the emergency brake cannot be locked except when running switch is either in “neutral” or “charging” positions, and cannot be released until switch is thrown into “running” position. This necessitates that the driver turns off the running switch when leaving the vehicle. It also prevents anyone from releasing the brake while the vehicle is standing, if switch handle is removed. This means the vehicle is left alone in safety. As the brake cannot be released until switch is thrown on, it reminds the driver of that fact upon his return to the vehicle. A further interlock provides that the running switch can be thrown into the “running” position only when the controller is in “neutral” position. This prohibits the accidental starting of the vehicle, which might happen if the controller had been put on during the driver's absence and upon his return he threw on the running switch without looking at the controller.

No. 5.—40-cwt. Tip Van (Edison Accumulators, Ltd.).

This is one of the vehicles exhibited directly by Edison Accumulators, Ltd. (2 and 3 Duke Street, Piccadilly, S.W.), several of whose cars are also shown by users. The arrangement of the chassis of the tip van is generally similar to that of the bare chassis described below, under No. 6, with slight modifications, such as the position of the battery rendered

necessary by the form of the body, which requires the battery to be slung under the frame instead of mounted above it, as in

No. 5.—EDISON 2-TON TIP VAN.

No. 6. The vehicle is built for a load of 2 tons and has a speed of 12 to 13 miles per hour. The battery consists of 60 cells of 300 ampere hours.

**No. 6.—G.M. Type Chassis
(Edison Accumulators, Ltd.).**

The bare chassis exhibited by Edison Accumulators will enable the constructive details to be followed more completely than the complete vehicle. The chassis is of a type that is made in several different sizes for loads from 20 to 40 cwt., and is now used in practically all the company's larger commercial vehicles. It is driven by a single motor, rated at 40 amperes at 72 volts, and running at a maximum speed of 900 r.p.m., situated in the rear of the frame. This drives through a longitudinal flexible shaft of twisted strap form on to a level differential countershaft, while the final drive is by side chains to the rear wheels in the usual way. Unsprung weight is thus reduced to a minimum, and quite a light back axle is permissible. The control is entirely by a lever over the steering wheel, which communicates with a controller under the small bonnet in front of the dash-board, which contains all the control gear in a most easily accessible position. A plain drum type controller of substantial construction is used, providing for five forward and two reverse speeds, obtained by a series parallel arrangement of the field coils combined with series resistance. There is also a switch on the dash-board worked by a removable key with "running," "charging," and "off" positions, and an ampere-hour meter is provided, with the dial neatly let in flush with the dashboard. The control resistance is made up of cast grids in a steel frame, and is mounted under the front end of the frame. There is no pedal control to the motor. The two pedals are both for brakes, one on the motor shaft and the other the usual expanding wheel brake. There are no side levers whatever, but both foot brakes are provided with ratchets, so that they can be kept on when desired, and either can be released by pressure on a knob with the heel of the other foot. The battery is not slung under the frame, as in some electric vehicles, but is carried in a box, the front portion of which forms the driver's seat. In this rigid chassis shown, the battery consists of 60 cells of the "A 6" type of 225-255 ampere-hour capacity, and an

average voltage of 70. The weight of the battery complete is 1,260 lb., and of the chassis without battery 3,061 lb. The normal charging rate is 45 amperes for seven hours. A speed of 10 to 11 m.p.h. is obtained with full load, and on good roads 40 to 50 miles can be covered on one charge, but an extra 15 miles can be obtained by a one-hour boosting charge of the battery. For loads up to 40 cwt. a larger battery of 60 A 8 cells of 300 ampere-hours is employed. It will be seen from these notes that the main characteristics of the design are simplicity and accessibility, and to this is added a robustness of construction which is an equally important feature.

It is unnecessary to recapitulate the constructive features of the Edison alkaline nickel-iron battery. Those unfamiliar with its features may be referred to detail articles which appeared in ELECTRICAL ENGINEERING, October 12th, 1911, Exhibition Supplement, page 67, and May 19th, 1910, page 319, as well as to Messrs. Watson and Mitchell's paper on "Electric Automobiles," read at the 1913 Convention of the I.M.E.A. (see ELECTRICAL ENGINEERING, June 26th, 1913, page 377).

**No. 7.—20-cwt. Edison Covered Delivery Van
(J. Pullar and Sons, Ltd., Perth).**

The chassis of this vehicle is generally similar to that shown as No. 6. The body is that of a covered delivery van, with a carrying capacity of 20 cwt., and the vehicle is capable of a maximum speed of 12 miles per hour. The battery is composed of 60 cells of the Edison A 8 type of 300 ampere-hours capacity.

**No. 8.—"Baker" 20-cwt. Box Van
(Wolseley Motors, Ltd.).**

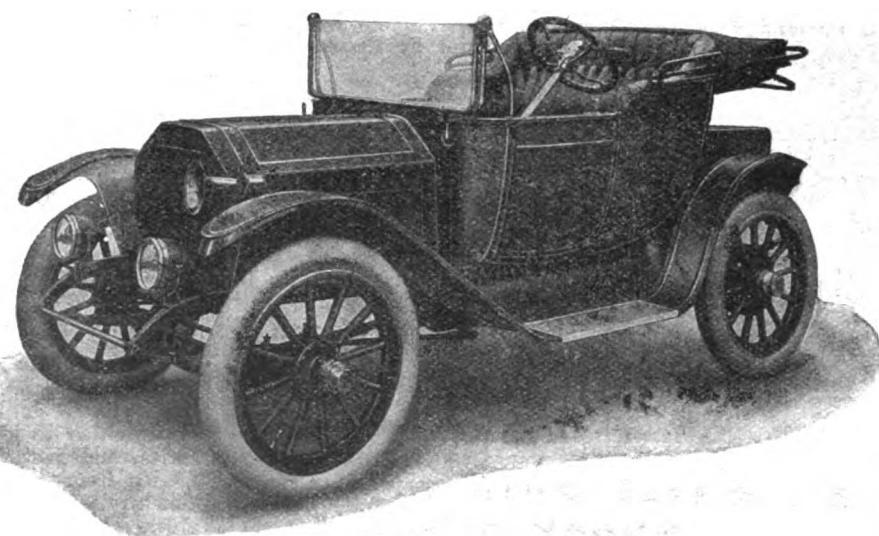

The Baker commercial chassis, which is supplied by Wolseley Motors, Ltd. (Adderly Park, Birmingham), is also of the type driven by a single motor. This drives a differential countershaft through a short, enclosed saw-tooth chain, while the final drive is by enclosed roller chains to the rear wheels. This vehicle carries a load of 20 cwt., a speed up to 10½ miles per hour, and is equipped with a 42-cell "Ironclad Exide" battery of 157 ampere-hours' capacity.

**No. 9.—"Baker" 40-cwt. Chassis
(Wolseley Motors, Ltd.).**

This is a 2-ton chassis of the same type as the previous vehicle (No. 8), only larger. It is capable of a speed of nine miles per hour, and the battery, which is also of the "Ironclad, Exide" type, is of 42 cells of a capacity of 189 ampere-hours.

**No. 10.—Three-seated Passenger Car
(Croydon Corporation).**

This is an example of a passenger car equipped with the Edison battery, and is a car that is in daily use by the Distributing Engineer and Sales Superintendent of the Croydon electricity undertaking, and we understand that it has run its first five months without repairs of any kind. The nature of its work is such that it is only used on the average about 24 miles per day, and it is calculated that the actual running costs have been at the rate of 2·56d. per mile with electricity at 1d. per unit. To this must be added 3·20d. for depreciation. The car has the battery under the bonnet in front, and closely resembles an ordinary petrol car in appearance. From the illustration it will be noticed that the steering wheel is on the left-hand side,

No. 10.—EDISON BATTERY PASSENGER CAR (CROYDON).

which is due to this chassis having been of American origin. Similar cars are, however, now obtainable with the steering

wheel on the right, which, for driving in this country, is preferred by most people. The car is capable of speeds up to 18 and 20 miles per hour, and is equipped with 60 "A 4" Edison cells of 150 ampere-hours capacity. The drive is by a single motor through a worm-gearred live back axle. The control is by means of a series parallel arrangement of the two sections of the battery, in conjunction with series parallel arrangement of the field coils and resistance steps. The controller hand is mounted over the steering wheel.

No. 11.—"Opel" Covered 10-cwt. Delivery Van (Poplar Borough Council).

This is a similar car in general respects to the Marylebone van (No. 3), except that it is equipped with a 44-cell E.P.S. battery, with a capacity of 125 ampere-hours.

No. 12.—Open 15-cwt. Delivery Van (Heston and Isleworth Council).

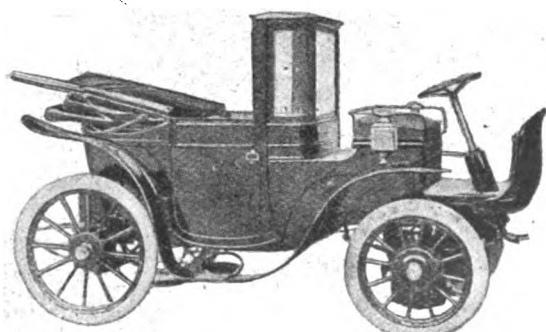

This is a similar vehicle to the last-mentioned (No. 11), except that it is of rather larger size; it is capable of a speed of 14 miles per hour, and has a 44-cell Hart battery of 120 ampere-hours capacity.

No. 13.—Electric Landaulette (Hertford Street Motor Co., Ltd.).

This is an example of a type of four-seater landaulette formerly known as the "electromobile," which has long been familiar in the London streets. The chassis is of British manufacture, being made throughout by Greenwood and Batley, Ltd. (Leeds). A single motor rated at 8 h.p. at 1,500 r.p.m. (continuous rating) is employed, driving the live back axle through enclosed double reduction helical gear. The motor is of special design with two separate armature windings, each with its own commutator, so that this can be grouped in series or parallel. The controller gives three forward speeds, two electric braking positions, and one reverse speed. The controller drum is situated in a horizontal position under the floor boards in front of the driver's seat, and is actuated by a hand lever mounted on the steering column immediately under the wheel. A quick break switch is connected with the foot brake, so that when it is applied, the main circuit is broken, no matter what is the position of the controller. Various makes of battery are employed, the standard size is 45 cells of 150 ampere-hours capacity. These are placed in a single box slung under the car, and very easily removable. Further details of this chassis were given in ELECTRICAL ENGINEERING, Vol. 1, p. 653, April 11th, 1907, and the very complete arrangements for looking after the batteries were described in a special article on the Company's garage in Hertford Street in ELECTRICAL ENGINEERING, Vol. II., p. 792 (Nov. 21st, 1902).

No. 14.—Electric Landaulette (Kriéger Electric Carriage Syndicate).

The Kriéger Electric Carriage Syndicate (48A Gillingham Street, S.W.) will be showing one or possibly two of their landaulettes, of which a considerable number are at work in London. The Kriéger system of drive by motors geared to the front wheels, and arranged to turn with them for steering purposes, had its origin in France some years ago, although it was subsequently adopted in cars made in other countries. The two motors which drive these landaulettes are each rated at $3\frac{1}{2}$ h.p., and a special feature of the system is that they are compound wound. The first four speeds are obtained by the controller

No. 14.—KRIÉGER LANDAULETTE.

putting both motors in series with either compound or series fields, and utilising either half or full voltage of the battery, and the two highest speeds are obtained by connecting the motors in parallel with series or compound fields. Owing to the presence of the shunt windings a regenerative braking effect can be obtained on certain steps of the controller. In the latest types of vehicle a pedal control is provided by which the motors may be cut out of circuit immediately, and cut in again through a rheostat. The vehicles shown will both be equipped

with Naylor batteries, which have been found very durable and to be specially able to stand rapid charging. Forty-six cells are carried, half in the front portion, and half in the rear of the car. The ordinary size of battery used has a capacity of 175 ampere-hours, which is sufficient for about 45 miles on one charge, but a larger battery can be provided in the space available. The ordinary speed attained is about 20 miles per hour, but it is quite easy to run up to 30 miles per hour when required. The carriage bodies provided are of high quality, and the vehicles do not exceed 31 cwt. in weight complete.

No. 15.—"Millburn" Coupé (Heath's Garage, Ltd., Birmingham).

This is another type of private passenger car for town work, seating four persons and travelling at speeds up to 20 miles per hour. The motor drives a worm-gearred live axle, and the car is equipped with a "Philadelphia" lead battery of 20 cells of 204 ampere-hours capacity, thus being of an unusually low voltage.

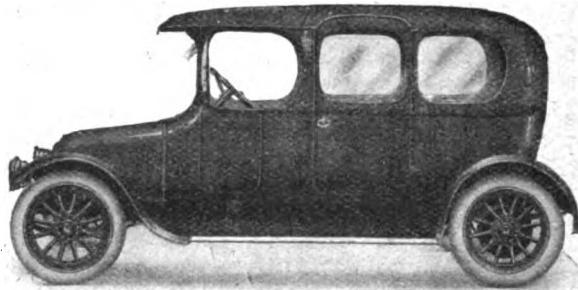

No. 16.—"Lang" Coupé (Heath's Garage, Ltd., Birmingham).

The same firm are showing a second four-seated coupé of another style, geared for a rather higher speed (24 m.p.h.), and equipped with an Ironclad Exide battery of 41 cells of 137.5 ampere-hours capacity.

No. 17.—70-cwt. "Baker" Electric Lorry (Wolseley Motors, Ltd.).

This is a heavier size of the Baker vehicle represented in its lighter types by Nos. 8 and 9. It has a carrying capacity of $3\frac{1}{2}$ tons at 8 to 9 miles per hour, and is equipped wth a 42-cell "Ironclad Exide" battery.

The above are all the cars mentioned in the official programme, but it is probable that one or two more will be officially present. We understand, for example, that the use of the Edison battery to propel a luxurious pleasure car will be demonstrated by Edison Accumulators, Ltd., in a vehicle similar to that illustrated here. This handsome carriage has an all-metal domed limousine body mounted on a chassis made by Arrol-Johnstone, Ltd., driven by a single motor rated at

EDISON LIMOUSINE.

45 amperes at 60 volts. This is situated near the middle of the frame, and drives the live back axle through a worm gear. The battery, neatly packed away in the lower part of the vehicle, partly in front and partly behind the motor, is composed of 60 "A 5" Edison cells of 188 ampere-hours capacity, giving 50 to 60 miles on one charge. The control gear is of a simple nature. Plain series resistances are used on the first few steps, and as there is only one motor with a single commutator series parallel, control is not made use of in any way, nor is there any alteration in the grouping of the cells, which are kept permanently in series.

The Electrical Emergency Service.—We are still able to receive a few more names for enrolment in the Electrical Emergency Service. Although the waiting list is now fairly long, owing to geographical considerations, it may not be long enough to supply a sudden call for men in some districts of London. As our readers know, the object of the service is to do the work of switchboard attendants, who desire either to join the Army or to work in munition factories, and gentlemen of every rank in the electrical profession from the highest to the lowest are volunteering for this service. An application form will be found on p. vii.

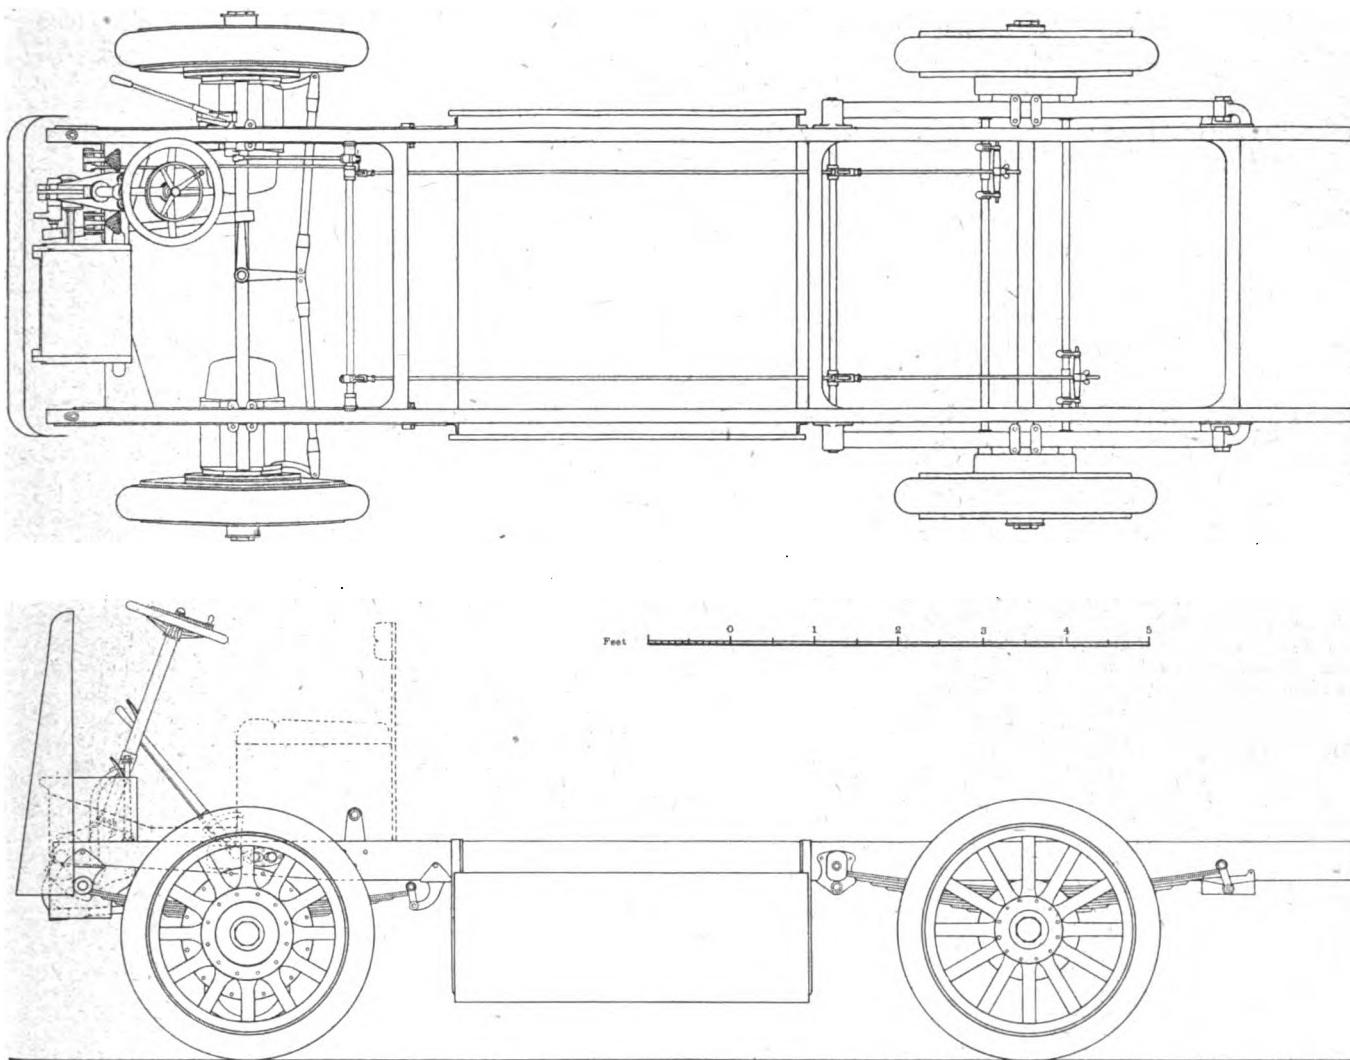

Physical Society.—At the meeting to be held at the Imperial College of Science, South Kensington, S.W., on Friday, June 25th, the two following Papers are on the agenda:—(1) "A Theory of Electrical Resistance of Metals," by Sir J. J. Thomson, F.R.S.; (2) "On an Unbroken Alternating Current for Cable Telegraphy," by Lieut.-Col. Squier (U.S.A.).

THE ORWELL COMMERCIAL ELECTRIC VEHICLE

CONSIDERABLE progress has been made in the manufacture of the first batch of a new series of electric commercial vehicles which are being constructed at Ipswich by Ransomes, Sims & Jefferies, Ltd., and for which the sole selling agents are Mossay & Co., Ltd. (Queen Anne's Chambers, Tothill Street, Westminster). It will be remembered that this firm were at one time agents for a foreign-built electric vehicle (see ELECTRICAL ENGINEERING, Vol. X., p. 143, March 12th, 1914), and we must congratulate them on the promptness with which, on the revelation of the true character of the country of this vehicle's origin, they made arrangements for its replacement by an entirely British vehicle of a design which embodies many improvements upon its predecessor.

in "Timken" conical adjustable roller bearings. They are compound wound, and are of 2·5 or 2·75 h.p. normal rating, according to the load to be carried.

The control gear embodies considerable improvements, and is designed and made by G. Ellison (Birmingham). The whole of the control mechanism is contained in an aluminium case bolted to the front cross-member of the frame, and, in addition to containing the two control drums, charging plug arrangements, &c., has the instruments mounted on the top. The main control drum is for altering the motor connections, and is worked by a lever on the top of the steering column. It provides for fine forward running positions, a rheostatic braking position, and one reverse. The battery always had all its cells in series, and the changes effected on the various steps are as follows:—Forward speeds: 1st speed, armatures and series fields all in series, with shunt windings across the battery in series; 2nd speed,

PLAN AND ELEVATION SHOWING GENERAL ARRANGEMENT OF CHASSIS OF ORWELL ELECTRIC COMMERCIAL VEHICLE.

An elevation and a plan showing the general arrangement of the chassis is shown in the figure. The feature of front drive is retained, with separate motors geared to the road-wheels and mounted so as to move with them for steering purposes. The control is all mounted behind the lower part of the dashboard, and the battery box is slung below the centre of the frame, so that the maximum platform area is available for the load. Three sizes are standardised to carry 1½, 2, and 2½ tons respectively, all of the same general over-all dimensions, but differing, of course, in the size of the motors and mechanical proportions.

The motors drive through single reduction helical gear, and the position and angle of the steering pivots is such as to protect the steering wheel from road shocks, so that remarkably easy steering is obtained, notwithstanding the fact that the unsprung weight of the motors has to be turned with the wheels. The motors are made by Ransomes, Sims & Jefferies themselves, and are totally enclosed with aluminium end shields and easily removable watertight covers. They run

the same, with the shunt windings cut out; 3rd speed, shunt windings as in 1st speed, armatures still in series, but series windings cut out (this position gives a regenerative braking effect when the speed exceeds 6 or 7 miles per hour, and can be used for coasting downhill); 4th speed, motors in parallel, with shunt fields as in 1st speed; 5th speed, the same, with shunt windings cut out. The reverse is with the motors in series. Current is never broken on this controller, but there is an auxiliary controller worked by a pedal, which breaks the circuit when pushed forward and makes it, and gradually cuts out resistance when let back. This is mechanically interlocked with the main controller, so that the circuit must be broken whenever the main controller is moved. The pedal is thus worked in driving exactly like the clutch pedal of a petrol car. The auxiliary controller is fitted with a magnetic blow-out. Another important feature of the interlocking arrangements is that the charging plug can only be inserted when the controller is in the "off" position, nor can the vehicle be started while

the charging plug is in place. Also when the charging receptacle is free to receive the plug the whole controller is necessarily dead, so that it can be opened up for cleaning and inspection, or taken to pieces during charging. Another point to which special attention has been paid is the provision of a spring step-by-step movement to the auxiliary controller combined with a suitable amount of backlash to the pedal so that it is impossible to stop between two resistance steps. There are, in addition to the electric brakes, two internal expanding brakes, actuated by a pedal and side lever respectively, on the rear wheels.

The battery of 40 cells is carried in boxes, which can be let down on to rollers and slid out sideways in sections from either side for inspection, or drawn right out for replacement. Either "Ironclad Exide" or "Tudor" batteries can be supplied under excellent guarantee conditions and maintenance contracts. The capacities vary from 102 to 280 ampere hours, and a mileage of 35 to 45 per charge is obtainable, with a maximum speed on the level of 11 to 12 miles per hour.

The chassis is suitable for any kind of body. A special design of top van has been prepared, involving a very ingenious tipping mechanism worked by two screws of unequal pitch, which slides the body out at the same time as tipping it. This can be worked by a small motor if desired. Two dustcarts on this principle for Birmingham and for Wolverhampton are already on order, and other cars under construction include a 30-cwt. van for the Midland Railway. An improved type of tower waggon body can also be fitted. The company have some other types of vehicle in preparation, among which we understand is an electric platform luggage truck and a tractor for dealing with ordinary vehicles involving some novel features, which we hope to refer to at a later date.

MUNICIPALISATION OF THE BERLIN ELECTRICITY WORKS

To Prevent a Bread Famine!

IN the history of municipal electrical control nothing has been more startling than the sudden decision of the Berlin Municipality to take over the electricity supply undertaking owned by the large and successful company, the Berliner Elektricitätswerke, which has hitherto been responsible for the whole of the electricity supply in Berlin. The works are to be transferred to the Municipality on October 1st, but the decision was arrived at by the Berlin authorities on February 23rd, and confirmed by the Town Council in March. The purchase price will be about £6,500,000.

This decision was quite unexpected, and the circumstances which led to it were certainly remarkable. The A.E.G. Co. of Berlin, with which the Berliner Elektricitätswerke has always been intimately connected, are also interested in a very large electric power station which is being erected near Bitterfeld, and is working in conjunction with the Golpa-Jessnitz Colliery. It was from these works that current was in future to be supplied to the Berlin Electricity Works, although the distance is over eighty miles. Last February it was announced, however, that this would no longer be possible, as the Golpa-Jessnitz-Bitterfeld people had entered into a contract to supply 500,000,000 units a year for fifteen years to the Bavarian Nitrogen Works for the production of chemical fertiliser. This supply is to start by the end of the present year, and, reading between the lines of the German newspaper announcements, it appears not improbable that the scheme has directly or indirectly the support of the German Government. This may have been in view of the necessity of maintaining and increasing the wheat crop, in spite of the present practical impossibility of Germany obtaining chemical fertiliser from South America, due to the blockade by the British Fleet, but it is also just conceivable that the "fixation" of nitrogen which the Bavarian nitrogen works has in contemplation is not merely for the purpose of manufacturing calcium nitrate for the fertilisation of the soil, but is primarily for the production of nitrates for the manufacture of explosives.

In any case, it seems that the electric supply company anticipated considerable difficulty in obtaining the necessary coal for the Berlin electricity works without being able to rely on the Golpa-Jessnitz Colliery, and has therefore been unwilling to renew its agreement with the Berlin municipality for the public and private electricity supply in that city.

We understand, from information published in the German Press and received by us through our correspondents in Switzerland and Denmark, that the whole of the electricity

supply to Berlin and its suburbs will be taken over by the municipality, and will be administered by a Board of fourteen members. The technical managers will be Dr. H. Passavant, E. Wikander, G. Wilkens, and Dr. Brühl.

With regard to the Bitterfeld power station, it is stated that in addition to the contract for 500,000,000 units a year already mentioned, a further output of 250,000,000 units is being spoken of for another purpose. The transmission pressure is to be 80,000 volts, and eight generating sets of an aggregate capacity of 180,000 kw. are to be put down—four of them immediately.

IMPORTANT LINKING-UP SCHEME FOR LONDON

AN important scheme for linking up the generating stations of the Battersea, Fulham, and Hammersmith Councils was to have come before the Hammersmith Borough Council yesterday, after we had gone to press. We hope to give the result in our next issue. Upon the scheme coming into operation it will be possible, by arrangement, to shut down during certain times two out of the three central stations concerned and supply the whole of the three areas from one station. The same advantage would apply to week-ends and Bank Holiday periods, thereby ensuring a substantial saving in labour and fuel by the three authorities, as well as affording great advantages in the execution of repairs to the steam plant. A further advantage to be gained by each of the three authorities concerned is that it will not be necessary for each to have such a large reserve plant in their respective stations as hitherto, as it is proposed to provide that a stand-by supply as well as a bulk supply shall be furnished if required. In a report the Electricity Committee state that the question has recently become somewhat acute, owing to the fact that the Battersea Council must meet certain large additional demands for electricity in the immediate future. This can only be done by an extension of their existing station or by putting into operation at an early date the proposed linking-up scheme. In these circumstances, the Borough Council is recommended to agree to the proposal to link up the three stations.

The scheme provides for laying a connecting cable between the generating stations of the three authorities at an estimated cost of £17,441, to be borne in equal shares. In addition, each authority will bear the cost of the necessary transforming apparatus, meter switches, and the buildings for such plant to be placed at each generating station, so that the total estimated cost to each Borough is as follows:—One-third part of cost of connecting main, £5,813; transforming apparatus, &c., £2,500; total, £8,313.

The Electricity Committee remarks that in all probability no difficulty will be placed in the way of the Council obtaining a loan for these sums, to be repaid on the usual terms and within the usual periods, should they decide to go forward with the work. It is suggested that the agreement between the three authorities should cover a period of twenty-five years, after which, in the event of the agreement being terminated, the authority within whose district the connecting mains and the extensions thereof are situate will take over such mains upon a proper valuation. The ultimate estimated cost, therefore, to the Hammersmith Council will be £8,313, less the residual value of the mains and plant in twenty-five years' time, and the Committee are advised that such residual value ought to be a very considerable sum.

The details of the proposed agreement are still under consideration, and it is proposed in due course to submit an estimate of the capital expenditure involved in the proposal to the Finance Committee for consideration and report. In the meantime, however, in view of the fact that the Battersea Borough Council are compelled to consider at an early date the furnishing of the additional supply above referred to, it is important that the other Councils concerned should express their views generally upon the scheme.

The Faraday House Journal.—The current issue of the magazine and journal of past and present students of Faraday House contains particulars of the part being played in the war by many Faradians, as well as other news and a technical article on the "Third Harmonic in Transformers."

Obituary.—We regret to note that Major E. L. Baddeley, of the 8th Battalion Lancashire Fusiliers, has been killed in action at the Dardanelles. Major Baddeley was secretary to W. T. Glover & Co., Trafford Park, Manchester.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,447.

Why have the so-called "non-arcing metals" not been generally adopted for fuse-wire?
(Replies must be received not later than first post, Thursday, June 24th.)

ANSWERS TO No. 1,445.

Explain how to reverse the direction of rotation of a single-phase induction motor with squirrel-cage rotor, also of a single-phase repulsion motor with a D.C. armature, which is permanently short-circuited.—"J. B."

The first award (10s.) is made to "J. G. M." for the following reply :—

Fig. 1 shows diagrammatically a single-phase motor and its starter. The starter consists of a choking coil and a

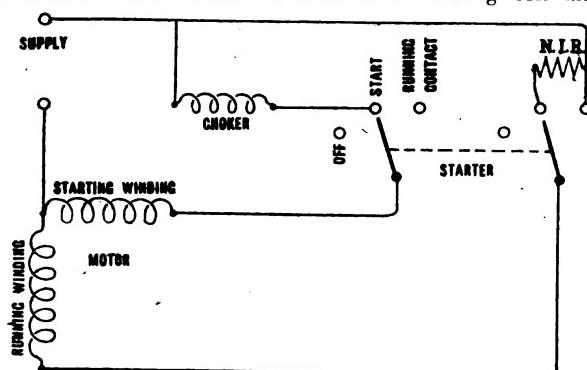

Fig. 1.

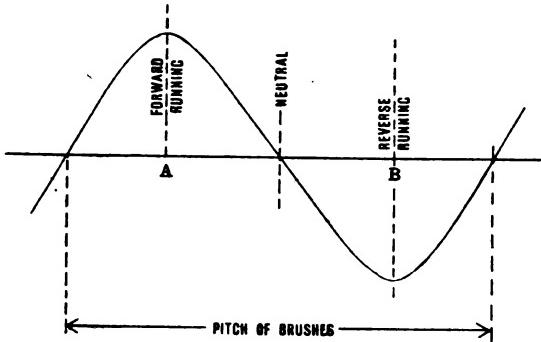

Fig. 2.

non-inductive resistance, which, by means of a switch, can be coupled in series with the starting windings and running winding respectively, and when the machine has got up speed the starting winding is open-circuited and the running winding is put directly across the supply. The choking coil

causes the current in the winding in series with it to lag, producing an approximation to a rotating field, the direction of which determines the direction of rotation of the armature. The machine may therefore be treated as a two-phase motor, and can be reversed by changing over the connections of either the starting or the running winding. The terminals of most machines are arranged in such a manner as to make this a simple operation. If for any reason it is not desirable to interfere with the connections in the machine, the same result may be obtained by altering the starter. The choker must be put in place of the resistance and the resistance connected in place of the choker. This will, of course, cause the current to lag in the other phase or winding, which will have the same effect as reversing the connections of one of the windings. In small machines the resistance is sometimes dispensed with, in which case care must be taken to avoid burning out the starting coil. As this is only in circuit for short periods, it is usually rated very high, and, if designed to run with the choking coil in series with it, will probably burn out if coupled directly across the supply. If therefore the choker is taken out of the starting circuit, it should be replaced by a non-inductive resistance to keep the current down to a safe value. In the case of repulsion motors the position of the brushes will have to be changed. The curve (Fig. 2) shows roughly how the speed varies with the brush position. Assuming the brushes to be in position A, which is the normal running position in forward direction; they will have to be moved to position B to produce the desired result. The new position is best determined experimentally; the brushes should be moved forward (or backward, whichever is most convenient) until the neutral point is reached when the armature will not tend to revolve in either direction. This position should be marked and then the brushes moved the same distance beyond this, which will be the best position for reverse running.

The second award (10s.) is made to "E. H." who writes as follows :—

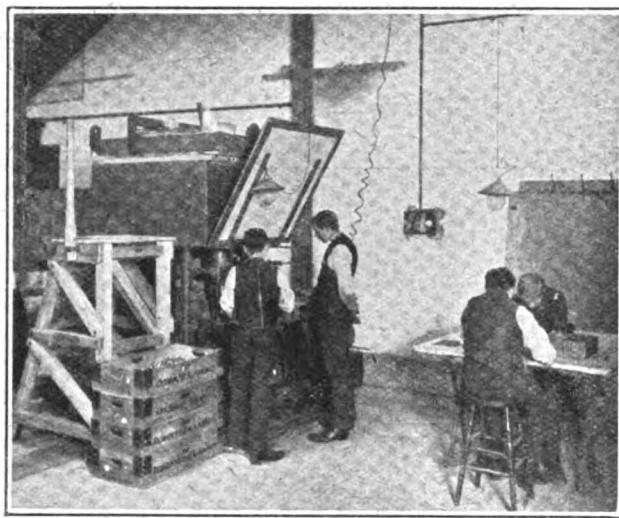

Single-phase induction motors are generally started by splitting the single phase in some way or another, or, in other words, by converting the machines temporarily into polyphase motors. One of the commonest methods of attaining this object is to wind the stator with two separate sets of coils—a "running" and a "starting" winding. In series with these are connected a resistance and a choking coil respectively, the effect of which is to cause the current in the starting phase to lag nearly 90° behind that in the running phase, and hence to produce a rotating magnetic field. With a squirrel-cage motor the values of the resistance and of the inductance of the choking coil must obviously be greater than with the slip-ring type. The rotation of such a machine is reversed by reversing the direction of rotation of the magnetic field. This can be accomplished in one of two ways: (1) by crossing over the leads to either the running or the starting phase, but not to both; or (2) by interchanging the resistance and the choking coil. In the case of a comparatively small motor starting under light load, a simple method of reversing the rotation is to switch only the running phase and its resistance across the mains, and start the motor by hand in the desired direction. The motor will then run up to speed without any difficulty. The single-phase motor of the simple-repulsion type is generally started by shifting the position of the short-circuited brushes. When the machine is at rest, and the brushes are connected to conductors which are midway between the poles, the equivalent of a transformer on no-load is obtained. If the brushes are shifted in either direction, the armature starts rotating in the opposite direction. Thus, suppose a clockwise rotation is desired, then the brushes must be shifted in a counter-clockwise direction. Were the brushes shifted until they were in contact with conductors from under the centre of the pole, the motor would again come to rest; it would then be acting as a short-circuited transformer, and take a tremendous current in the stator windings. A further shift of the brushes would cause the motor to reverse its rotation. If it were possible to move the brushes of a two-pole repulsion motor through a whole revolution, the direction of rotation would be reversed four times.

ANSWER TO CORRESPONDENT

F. B.—The new edition of the Standardisation Rules for Electrical Machinery of the British Electrical and Allied Manufacturers' Association can be obtained at the price of one shilling from the Secretary of the Association, King's House, Kingsway, W.C.

BRITISH MADE LAMP CAPS

HERE is a somewhat widespread belief that one of the most essential parts of an incandescent lamp, the cap, is always imported from abroad, though (as was announced in ELECTRICAL ENGINEERING, September 24th, 1914, p. 518) the Osram Lamp Works, Ltd., and the Robertson Lamp Works, Ltd., manufacture these at their Hammersmith factories. The illustration, which shows part of the cap-making

LAMP CAP MAKING AT THE OSRAM LAMP WORKS,
HAMMERSMITH, LONDON.

plant of the Osram and Robertson companies at Hammersmith, is, we believe, the first of an English cap-making plant to be published, and is thus of special interest. The Osram and Robertson Companies, moreover, manufacture every other part of their incandescent lamps at Hammersmith with the exception of the glass bulbs, which, as hitherto, are made at Lemington-on-Tyne. Both companies, therefore, are entirely independent of any foreign source of supply.

AN ELECTRICALLY DRIVEN SHOE FACTORY

MESSRS. W. EDWARDS & SON, of Norwich, have recently erected a three-storey factory on the banks of the river Wensum, that may be considered as the last word in up-to-dateness. The designers of this establishment

FIG. 1.—B.T.-H. ELECTRIC MOTOR, MOUNTED NEAR CEILING,
DRIVING TWO LINES OF SHAFTING IN MACHINE ROOM, MESSRS.
EDWARDS & SON, NORWICH. B.T.-H. ELECTRIC FLAT IRON USED
FOR "BACKING."

realised to the full that to light and drive factories by means of electricity is the safest, cleanest, most efficient, and least expensive method; for to every conceivable piece of ap-

paratus, and in any kind of factory, electric driving and lighting can be advantageously applied. Messrs. Edwards are fortunate in being able to secure their supply of electricity from the mains of the Norwich Corporation, whose charges are very low, making it an attractive centre for boot manufacturers who are contemplating fresh fields of operation. The maximum floor space has been secured by placing the B.T.-H. electric motors which drive the machinery near to the ceiling in iron cradles, grouping the machines they drive so that the smallest number of belts and line shafts are required. As it is a function of the electric motor to work equally well whether placed on floor, pillar, or ceiling, there has been no sacrifice in efficiency by placing the motors near the ceiling as Messrs. Edwards have done. Two sizes of B.T.-H. electric motors have been standardised for use throughout the factory, i.e., 10 h.p. and 15 h.p., with speeds of 1,000 r.p.m.

The advantages of electric drive may be summarised as follows :—

The cost is always proportional to the actual work done. Whether under- or overloaded, the electric motor is always highly efficient. No attention and few and inexpensive repairs are necessary. Electric motors are easily and quickly installed, and require no special foundation or alteration to existing arrangements. Electric motors are small and compact, and, if necessary, can be fixed to wall or ceiling. In any case, only a negligible amount of space is occupied. A single machine can be used at any time without running the whole power plant. Electric motors are perfectly safe, and factories equipped with them obtain preferential insurance rates. They create no fumes or dirt. They are vibrationless and practically noiseless. They can be started by simply throwing over a switch—which is an entirely "fool-proof" piece of apparatus. Extensions to the factory can easily be made. There is no need to instal more power than is neces-

FIG. 2.—B.T.-H. ELECTRIC MOTOR, 10 H.P., DRIVING MACHINERY
IN VELDT-SCHOEN MAKING ROOM, MESSRS. EDWARDS & SON,
NORWICH. MOTOR MOUNTED NEAR CEILING LEAVES FLOOR SPACE
CLEAR. MAZDALUX LIGHTING AND SPECIAL UNIVERSAL FITTINGS.

sary at the moment. Additional motors can be installed as required without disturbing the original plant.

The entire factory is lighted by electricity, drawn-wire Mazda lamps shaded by "Mazdalux" reflectors being used and arranged so that the light is concentrated on the work and not in the eyes of the operatives, there being an entire absence of glare, with a resulting saving of eye-strain to the operatives. In the case of special machinery, such as consols, stitchers, pull-over machines, &c., the fittings are of the "Universal" type with Mazdalux reflectors, enabling the operator to place the light in the most desired position. The equipment of the different departments consists of the latest types of shoe machinery supplied by the British United Shoe Machinery Co., Ltd., and the Singer Co.

The press room, which contains double open-end presses, "Nickole" evening and grading machine, twin sole moulder, "Planet" sole-rounding, "Acme" heel-building machines, universal slingers, and the usual complement of skivers, splitters, and preparing machines, is driven by a 15-h.p. motor. The "clicking" room, which contains clicking presses, is driven by a 10-h.p. motor. In this room the electric irons are used for "backing," and have been found extremely satisfactory. The machining room contains closing machines, button-hole machine, hand-meshed folder, power hammer, and edge-cementing machines, driven by the motor in the clicking room. The machine-sewn making room is driven by a 10-h.p. motor, and contains assembling machine, pull-over machine, lasters, wire grip backer, rotary pounding-up machine, sole sewers, leveller, channel closing and edge-raising machine, and cementing machine. The veldt-schoen department is driven by a 10-h.p.

motor, and contains a veldt assembling machine, laster, rotary pounding-up machine, rapid stitchers, veldt-trimming machines, wire grip tackers, channel-laying and sleeking machine, tack-pulling machine, universal slugger, and channel opener. The turn-shoe department is driven by two 10-h.p. B.T.-H. electric motors, and contains lasting machines, wire grip tackers, turn-shoe sewing machines, channeller, turn-shoe reforming plant, universal slugger, and heel-attacher. The finishing room, heeling department, and stock room are driven by two 15-h.p. B.T.-H. electric motors; the finishing room contains top ironing machines and polishing shafts; the heeling department contains

universal sluggers and lightning healer; the stock room contains a power monogram machine. The drying room is heated by electricity and fitted with electric fans. A 40-in. duplex dust-exhauster, driven by a 15-h.p. motor with special speed regulation, has been installed in the finishing room.

The British Thomson-Houston Co., Ltd. (Rugby), supplied all the electric motors for driving, the Mazda lamps and Mazdalux reflectors, and the electric irons, and the planning and carrying out of the electrical installation was done by Mr. R. A. Lower, of the Norwich Corporation.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 10th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

11,889/14. **Connection Box.** St. HELENS CABLE and RUBBER Co. and J. C. WHITE. Connection boxes for surface wiring in which the terminals fit in recesses, are arranged round a common centre, and are slotted in directions substantially parallel to the directions in which the cables enter. (Nine figures.)

12,047/14. **Electric Vehicles.** B.T.-H. Co. (*General Vehicle Co., U.S.A.*). A control system for electric cars in which the control gear is interlocked so that the controller is returned to the off position whenever either of the brakes is applied. The emergency brake is locked in position when the running switch handle is removed, and when the running switch has been moved to the off position it is impossible to move it to a running position unless the controller is in the off position. (Six figures.)

12,599/14. **Conduit Fittings.** SIMPLEX CONDUITS, LTD., and L. M. WATERHOUSE. A conduit fitting, comprising a body fitted with outlet branches, and having an inspection opening with a lid, also provided with an outlet, so arranged in relation to the others that when the fitting is placed in the angle between a ceiling and a wall, it is adapted to connect a line of conduit in the angle, with one along the ceiling and one up the wall. (Eight figures.)

12,906/14. **Lamp Lock.** G. WHARRAM. A lamp lock for bayonet-socket lamps, consisting of a metal plate with a hole for the bayonet pin of the lamp, and shaped to fit against the lamp cap, provided with a projecting tongue in such a position as to admit of being folded back into the holder slot, and a lip which can be folded over the outside of the holder. (Two figures.)

15,356/14. **Protective Reactances.** J. S. HIGHFIELD and W. DUDDELL. A graded protective reactance coil in which the condenser action between adjacent turns is smaller at one end of the coil than at the other, and gradually increases from end to end, the end with the small condenser action being connected to the line, and the other to the machine to be protected from surges. Arresters may be connected between points on the graded coil and earth. (Three figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: WALKER [Cable box compound] 17,686/14.

DYNAMOS, MOTORS AND TRANSFORMERS: COMPAGNIE DE L'INDUSTRIE ELECTRIQUE ET MECANIQUE [Dynamos] 13,159/14.

Electrometallurgy and Electrochemistry: HIGHFIELD [Smelting of ores] 4,937/14 and [Electric furnaces] 2,728/15; ASHCROFT [Fixation of nitrogen] 10,420/14.

Ignition: MCCLEMENTS [Sparkling plugs] 20,156/14.

Instruments and Meters: HAMILTON and FERRANTI, LTD. [Mercury meters] 12,926/14; BROGGER [Moving coil instruments] 14,557/14.

Storage Batteries: MARQUISE DES LIGNERIS [Light accumulator] 12,720/14.

Switchgear, Fuses and Fittings: BASTIAN [Resistances] 12,867/14; B.T.-H. (*G.E. Co., U.S.A.*) [Series parallel con-

trollers] 13,147/14; PIEPER und PIEPER [Automatic control for compressors] 16,130/14; PETERS [Reactance coils] 23,359/14; LUCAS and EDWARDS [Switches] 1,328/15.

Telephony and Telegraphy: AKTIESELSKABET ELEKTRISK BUREAU [Automatic telephones] 9,822/14; PEDERSEN [Wireless receivers] 12,364/14; MARCONI'S TELEGRAPH Co. and ROUND [Vacuous tubes used as magnifiers and producers of continuous electrical oscillations] 13,247/14 and [Production of continuous oscillations] 13,248/14; HULTMAN [Telephone exchanges] 13,362/14; GOLDSCHMIDT [Mechanical selector for wireless receiving apparatus] 15,082/14; WILEY [Printing telegraphs] 21,538/14; BELLINI [Directive wireless telegraphs] 22,879/14; MARCONI'S WIRELESS TELEGRAPH Co. and ROUND [Cathodes for oscillation tubes] 6,476/15.

Traction: MAJOR [Tramway rail joints] 20,635/14.

Miscellaneous: FULLER, FULLER, and FULLER [Batteries] 18,713/14; FARNSWORTH [Vapour electric rectifiers] 1,870/15.

Amendments made

*5,328/13. **Sifting Machine.** C. W. COMBS. This specification, which describes an electrically-driven sifting machine, has been amended by way of disclaimer.

Opposition to Grant of Patents

9,637/14. **Telephones.** E. C. R. MARKS (*Electrical Experiment Co., U.S.A.*). Opposition has been entered to a grant on this specification, which describes transmitters with rigid diaphragm lightly supported by pneumatic cushions exerting an aperiodic resilience, and permitting the diaphragm to vibrate as a whole in accordance with sound vibrations.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

12,382/01. **Electric Drills.** G. F. CAMPBELL and S. T. ISHERWOOD. Portable electric drilling machines, dispensing with the use of flexible or jointed shafts, with the motor mounted on trunnions and a telescopic shaft.

12,721/01. **Fuses for Explosives.** H. and H. TIRMAN. A machine for making electric fuses for cartridges or explosive charges.

12,739/01. **Driving of Centrifugals.** G. POTT and R. WILLIAMSON. Driving of centrifugal separators, &c., by a motor coupled to a loose sleeve, which drives the main vessel through a centrifugal friction clutch.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: A BLONDEL [Enclosed flame arc lamps] 4,677/06.

DYNAMOS, MOTORS AND TRANSFORMERS: B.T.-H. CO. (*G.E. Co., U.S.A.*) [Control of motors actuating water-tight doors of ships] 4,513/06.

Electrochemistry and Electrometallurgy: F. I. GIBBS [Electro-deposition] 4,410/08.

Ignition: A. J. BOULT (*L. Macquaire*) [Sparkling plugs] 4,991/04.

Switchgear, Fuses and Fittings: F. W. SUTER [Holder for tubular lamps] 4,608/08.

Miscellaneous: H. HIRST and S. D. WHITE [Burglar alarms] 4,468/07; H. W. RAVENSHAW, V. G. MIDDLETON, and W. E. TOWNSEND [Magnetic clutches] 4,849/06; W. D. WHYTE [Ship's compasses] 4,885/06.

"WITTON" HANDGUARD CUT-OUTS

UNCEASING endeavours have been made by the General Electric Co., Ltd. (Witton, Birmingham, and 67 Queen Victoria Street, London, E.C.), to develop lines of switch-gear and accessories which shall comply to the full with Home Office requirements for the protection of the operator. For many years the Company has been supplying a shielded cut-out complying with these regulations, but it has recently improved upon this design by the introduction of "Witton"

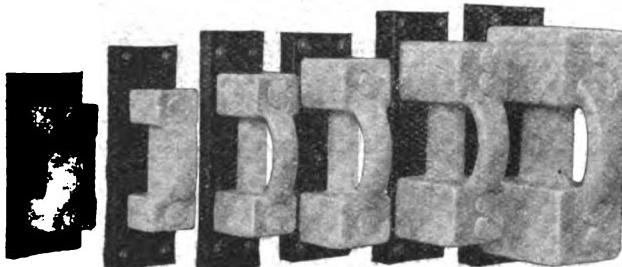

FIG. 1.—RANGE OF "WITTON" HANDGUARD FUSES.

handguard cut-outs, which are made in an extensive range, a few of the sizes being shown in Fig. 1. The object of this new design is to provide a completely protective guard for the hand, precluding the possibility of a live contact being touched while removing or inserting the fuse-carrier. The handle and carrier is composed of one porcelain block enclosing the contacts of the fuse-carrier and the clips on the base. The operator is, therefore, able to get a firm grip of the handle without the hand coming in the vicinity of live parts. In addition, the fuse possesses a self-aligning contact of new design carried on the fuse-carrier. It is mounted on the porcelain carrier by a stud projecting horizontally into the porcelain and held by a nut, the recess for which is seen from the front of the carrier and is closed by a porcelain cap

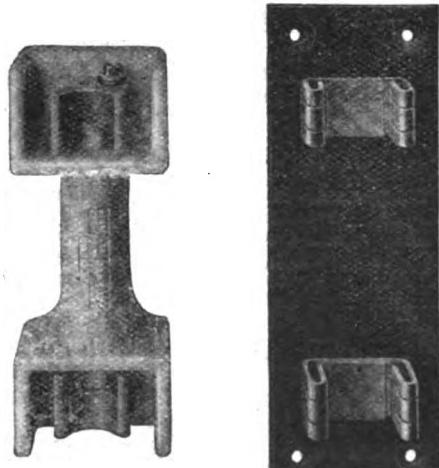

FIG. 2.—CONTACTS ON CARRIER, AND CLIPS ON BASE OF "WITTON" HANDGUARD CUT-OUT.

cemented in. The contact is not held tightly against the porcelain, but is separated from it by a spring washer, which gives the contact a small amount of freedom in every direction without interfering with its general rigidity. This freedom is adequate to enable the contacts to adjust themselves to meet any want of alignment in the clips.

A further feature of the handguard cut-out is its adequate ventilation. As will be seen from Fig. 2, each contact is cut away at the base so that ample facilities are provided for the access of air to the fuse wire. The latter is carried in the usual asbestos tube which passes through the tubular carrier. The cut-out is made in a number of sizes, ranging from 15 to 600 amperes, and the Company has not changed the prices as compared with its older "Home Office" pattern.

**TENDERS INVITED AND PROSPECTIVE BUSINESS****Generating Stations, Sub-Stations, Mains, &c.**

Australia.—The Melbourne City Council requires a D.C. generator. Specifications, &c., from Messrs. McIlwraith, McEacharn & Co., Biliter Square Buildings, E.C.

Eastbourne.—The Electricity Department requires about 160 ft. of 14-inch cast-iron circulating water piping and valves. Borough Electrical Engineer. June 26th. (See an advertisement on another page.)

Salford.—An additional 5,000-kw. turbo-alternator is to be installed at the Frederick Road power station, at an estimated cost of £16,200.—Twelve months' supply of maximum-demand indicators, motor carbon-brushes, tools, &c. Borough Electrical Engineer.

West Hartlepool.—An application is to be made for a loan of £1,000 to meet the next three years' requirements in respect of mains.

Wiring

Dublin.—Technical schools, 18 Rutland Square. Secretary, Technical Education Committee. June 21st.

London.—Four blocks at Grove Fever Hospital, Tooting Graveney, S.W. W. T. Hatch, Metropolitan Asylums Board, Embankment, E.C. June 30th.

West Bromwich.—Electric lighting of new buildings in Great Barr Park for Walsall & West Bromwich Unions Joint Committee. Architect, G. McMichael, 105 Colmore Row, Birmingham. July 5th.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Ellesmere Port.—New Council offices (£5,500).

Glasgow.—Springbank school. Clerk, School Board Offices, 129 Bath Street. June 19th.

Heywood.—Warehouse for T. Isherwood & Co.

Ilkley.—New school.

London.—Labour Exchange, Canning Town. H.M. Office of Works, Storey's Gate, S.W.

Salford.—Warehouse for Crompton & Co., Hope Street.

Tonbridge.—Post office and telephone exchange. H.M. Office of Works, London.

Miscellaneous

Brighton.—Twelve months' supply of electrical fittings for the Guardians. Clerk, Prince's Street. June 22nd.

Bristol.—Six or twelve months' supply of electrical fittings for the Guardians. Clerk, St. Peter's Hospital. June 21st.

Exeter.—Twelve months' supply of electrical appliances for Devon County Asylum. E. H. Harbottle, County Chambers, Queen Street, Exeter. June 29th.

West Ham.—Three months' supply of electrical fittings for the Union. Clerk, Union Road, Leytonstone.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Bradford.—The tender of the M. & G. Truck Engineering Co. has been accepted for 100 tramcar trucks, and that of Brown, Boveri & Co. for 200 tramcar motors.

Caledonian Railway Co.—A contract has been placed with the Edison & Swan United Electric Light Co. for Royal Ediswan lamps.

Chesterfield.—The following tenders have been accepted in connection with the £5,000 extension scheme:—400-kw. alternator, British Westinghouse Co., £877 10s.; boiler, superheater, and mechanical stoker, Babcock & Wilcox, £1,472; economiser, Clay Cross Co., £359.

Stoke-on-Trent.—Messrs. Venner & Co. have received a twelve months' contract for Chamberlain & Hookham meters.

Wallasey.—Contracts have been placed with the British Thomson-Houston Co. and Ferranti, Ltd., for a year's supply of A.C. meters.

We are informed by the Synchronome Co., Ltd., that their system of electric clocks is being installed in a large number

of factories and shipyards, and in many places now used as war hospitals. The electric time circuits at the Euston Station of the L. & N.W. Railway, at the Waterloo terminus of the L. & S.W. Railway, and at Port Sunlight for Lever Bros., are also being extended, in addition to other public buildings.

Messrs. Venner & Co. have received contracts for twelve months' supplies of Chamberlain & Hookham meters from the Paisley and Wallasey Corporations.

APPOINTMENTS AND PERSONAL NOTES

A proposal by the Barrow-in-Furness Electricity Committee that an honorarium of £100 be granted to Mr. H. R. Burnett, the Borough Electrical Engineer, has been rejected by the Council by 18 votes to 8. It was pointed out that the honorarium was not for extra work done during the war, but in recognition of strenuous work carried out by Mr. Burnett during the past two years.

The recommendation of the Newport (Mon.) Electricity Committee that a bonus of £100 should be paid to the General Manager and the Borough Electrical Engineer has been passed by the Corporation after some strong remarks by several members. It was pointed out that the two officials in question had succeeded in making the undertaking, which for years had made no profit, a successful one financially.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. Geo. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £96 to £97 (last week, £92 to £93).

Advance in Prices.—Kelvin, Bottomley & Baird, Ltd., announce an increase of 10 per cent. in all their prices owing to the rise in cost of material and labour.

LOCAL NOTES

Ashton-under-Lyne: *Street Lighting.*—Half-watt lamps are to be substituted for arc lamps for street lighting purposes.

Barrow-in-Furness: *Electricity Accounts.*—The accounts of the electricity undertaking for the past twelve months show a net profit of £3,163 against £513 in the previous year. The output has increased from 2 million to 3½ million units, and the generating costs have been reduced from 1¾d. to 0¾d. In submitting these accounts, Alderman Smith said that although there was every indication that the output during the next twelve months would be much larger, there must be set off against this the increased price of coal, a tender having been accepted that day at 5s. per ton more than last year.

Burton: *Low Charges Justified.*—Speaking at the last meeting of the Corporation, the Chairman of the Electricity Committee said that the low charges of the Electricity Department for power purposes have been fully justified, as the output had doubled in the last five years, and trebled in the past ten years. The profit-sharing scheme for the workmen had worked out at about 6 per cent. per annum on the men's wages, whilst the new plant recently installed at the electricity works had effected a saving at the rate of £2,000 per annum.

Hove: *Progress of Municipal Undertaking.*—In answer to questions at the last meeting of the Corporation, the Chairman of the Electric Lighting Committee said that as the Government had stopped all capital outlay, it was impossible to proceed with the linking up of the whole system to the Corporation's electric supply undertaking as was intended when the Hove Company was taken over. Pending this, the Corporation was compelled to continue the arrangements with Brighton for supply to the Aldrington district.

Kirkcaldy: *25 per cent. Increase in Charges.*—The deficiency on the accounts of the electricity undertaking for the past year is put at £3,000, to meet which it has been decided to increase the charges for lighting and power by 25 per cent.

Lincoln: *Electricity Accounts.*—There was an increase of 9 per cent. in the output last year, and the financial result was a net profit of £3,163 as against £2,715 in the previous twelve months. There was a decrease in working expenses of £543 due to economy effected by the new plant and the lower price of coal.

Lynn: *Public Lighting.*—The question of why the public lighting was being charged at a higher rate this year than last whilst the total number of units consumed was 25,000 less, was raised at the last monthly meeting of the Corporation. It was pointed out that since January there had been practically no public lighting, yet the amount charged was higher, and if there had been extra cost of production at the power station generally, then this should have been spread over the whole of the consumers. It was explained that it was impossible to alter the balance-sheet, but it had been arranged to reduce the public lighting by £300 for the current twelve months.

Taunton: *Electricity Deficit.*—The loss on the past year's working of the electricity undertaking is put at about £500, and an advance of 10 per cent. in the prices for current is recommended. This, however, is only to apply to lighting and power, a resolution that it should also apply to heating and cooking being lost.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

India Rubber, Gutta Percha & Telegraph Works Co.—It has been decided to abandon the half-yearly meeting this year on account of the war. The works at Silvertown are very busy in many departments, and it is anticipated that the year's results will be favourable, although the prices of labour and coal are considerably higher than last year. An interim dividend is to be paid on the 5 per cent. preference shares, and 2½ per cent. on the ordinary shares.

National Electric Supply Co.—An interim dividend of 2s. 6d. per share, less tax, is recommended on the ordinary shares.

The Association of Consulting Engineers.—The annual meeting of this Association was held on May 31st, Mr. G. Midgley Taylor presiding. The Chairman mentioned that the Committee had had under consideration the model general conditions of the Institution of Electrical Engineers, to which objections had been raised in some quarters. It was felt that general conditions should be applicable to contracts generally, and that works pertaining to the electrical branch of the profession should not require any special treatment, and the objections relate chiefly to points wherein the electrical conditions differ from those commonly accepted in other branches of engineering. The objections have been communicated to the Institution of Electrical Engineers. Another matter in which the Association has taken action is in opposing the issue of advertisements inviting engineers to send in applications and fees for carrying out engineering works, and it is probable that the Local Government Board will be approached on the subject. The following were elected to fill vacancies on the Committee:—Mr. W. Ll. Preece, Mr. W. J. E. Binnie, Mr. E. L. Mansergh, Mr. E. B. Taylor, Mr. W. Emmott, and Mr. F. W. Hodson.

Industrial Organisation.—In a contribution to the *Journal* of the Institution of Electrical Engineers, Lieut. W. Pollard Digby discusses the need for the adequate organisation of industry in this country, and shows how necessary it will be for many economic reasons, "when military war again gives place to the commercial warfare waged by manufacturing countries for food-stuffs and luxuries," to strain every nerve to apply system to our methods. He concerns himself particularly with means for obtaining the necessary information as to the requirements of overseas markets, as well as the doings of foreign competitors, and after a sketch of the present schemes of commercial attachés, trade commissioners, &c., put in a plea for a similar but much more extensive and thorough-going scheme of scientific and technical commissioners to carry on investigations relating to engineering and other industries all over the world. He discusses at some length the type of man required, the necessary equipment of education and experience, and outlines the kind of work to which these specialists in different branches should devote themselves.

SUMMARY

A DETAILED and illustrated description of the electrical installation at Lyons' new Regent Palace Hotel is commenced (p. 265).

A LARGE proportion of our space is devoted to a full report of the meeting of the Municipal Incorporated Electrical Association last week. On Thursday morning a report on the results of the point-five tariff was discussed at considerable length, and the disclosure that in some cases the tariff had resulted in decreased revenue in spite of large increase in units sold led to much comment. The discussion also dealt largely with the rateable value system of charging (pp. 267-271).

A REPORT on the use of electric vehicles in municipal service by Mr. Ayton was read in the afternoon and a number of members gave their experiences and ideas in the discussion (pp. 271-275).

THE point-fives meeting gave occasion for a debate of a thoroughly practical nature as usual (p. 275).

ON Friday the Annual General Meeting was held and the new Council elected. Mr. A. C. Cramb (the Acting-President) will continue as President (p. 276).

FURTHER progress has been made by the deputation representing gas and electrical interests regarding coal supplies (p. 279).

AN electric platform truck is described (p. 279).

A PROBLEM relating to the connecting up of motor starters is discussed in our "Questions and Answers" columns (p. 280).

AMONG the subjects of specifications published last Thursday at the Patent Office are heating elements, series generators, oscillation valve tubes for wireless telegraphy and telephony, automatic telephones, and joint-box compound (p. 281).

A 5,000-kw. turbo-alternator and water-tube boiler is

required at Halifax; a 2,000-kw. turbo-alternator, condensing plant, switch-gear, etc., at Erith; extensions estimated to cost £27,000 are contemplated at Luton, and an electric lighting plant is required for a sanatorium near Manchester (p. 281).

EXTENSIONS at Torquay have been stopped by order of the L.G.B.—A further scheme for the reconstruction of the Belfast Electricity Department has been prepared.—The Osram & Pope case has commenced (p. 282).

THE ELECTRICAL INSTALLATION AT THE REGENT PALACE HOTEL

THE electrical installation at this recently-opened London hotel—probably one of the largest in Europe, accommodating as it does 1,500 guests—is naturally on a very large scale, and we are indebted to Messrs. J. Lyons & Co., to Mr. A. H. Barker, the consulting engineer, who designed the ventilating, heating, and general engineering plant, and to Mr. Cushion and Mr. Goddard, the chief and second electrical engineers to the Company, for permission to inspect the arrangements and to publish some notes with regard to them.

The ventilation of the principal reception-rooms is on the "balanced" system. Washed air is supplied by two large centrifugal fans, but each principal room has its own

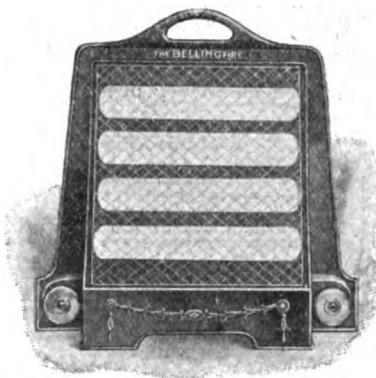

FIG. 1.—BELLING ELECTRIC FIRE AS USED IN THE BEDROOMS.

independent extract fan. There are two inlet ducts for each room, one for cold and one for hot air. In the kitchen there is a "false ceiling," which is perforated with numerous holes in removable panels, enabling the whole ceiling to be taken down for cleaning; this large ventilating space, in connection with a 4-ft. 10-h.p. "Sirocco" blower of sufficient power, enables the whole of the air to be changed in 1½ minutes. In the bedrooms fresh air can be introduced from adjacent areas, or warmed air from the corridors, at the will of the occupant, and the outlet of the vitiated air is through a trunk to the top of the building. The lavatories and baths are ventilated by extract fans, which withdraw the air to the roof. For this system of ventilation there are 31 fans, aggregating 82 h.p.; the two large main fans are each of 10-h.p. capacity. There are 300 miles of pipes and

about 15 miles of air ducts. Messrs. J. Jeffreys & Co., Ltd., were the contractors for the general heating and ventilating installation.

Probably the Regent Palace is the only hotel in which provision is made for electric heaters in every guest's bedroom. Those at present installed (about 120) are standard Belling electric fires of $1\frac{1}{2}$ -kw. size, as shown in the illustration. The general heating of the building is partly by hot-water radiators and partly by vacuum steam, and steam-pipes are, of course, employed for heating the air for ventilation. Electric thermostats made by the Steam Fittings Co., Ltd., are employed for controlling the temperature in both cases. This apparatus consists of a solenoid-operated double-beat valve (Fig. 2) operated by an electric thermometer, the latter depending for its action on the differential expansion of a combination of metals so arranged as to make and break a platinum contact when the temperature varies from that to which the thermometer is set by means of a regulating screw. When the desired temperature is reached, the circuit of a solenoid is closed, and the polar extension of its casing attracts a pure nickel disc attached to the double-beat valve, lifting the valve to its seat and shutting off the supply of steam. When the temperature falls, say, 1° Fahr., the contact is again broken, and the valve falls from its seat and allows steam to flow full bore.

In connection with the ventilating system, a 2-in. electric valve working at 15 lb. steam pressure is fitted to the steam coil in both main air ducts. These valves are each worked by an electric thermometer specially constructed for atmospheric control and set for 65° Fahr., which are fitted in the

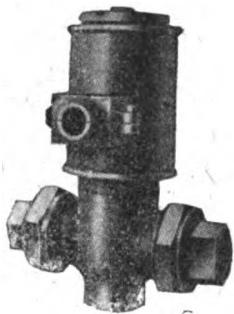

FIG. 2.

FIG. 3.

air ducts some considerable distance away from the heating coils to prevent their being influenced by direct radiation.

The hot-water supply is controlled similarly to the ventilating; in this case the thermometer is of special construction to admit of its being immersed in the liquid the temperature of which it is to control. Fig. 3 shows this special thermometer, which in action is precisely the same as the thermometer for air, and admits by means of the regulating screw a regulation of temperature over a range of 110° Fahr., and will maintain the temperature for which it is set (in this case 180° Fahr.) within 1° or 2° Fahr. There are five $1\frac{1}{2}$ -in. and one 1-in. electric valves working at 90 lb. steam pressure, each operated by an electric thermometer fitted to the calorifiers. The solenoids of all these electric valves take current direct from the 220-volts supply.

Before leaving the subject of the heating and ventilating, mention may be made of the "control room," although it is not yet equipped. This room will contain instruments to indicate the temperature and pressure of the air in any part of the building, the volume of air being supplied to the reception-rooms, the water level in each of the sixteen large water tanks, the boiler pressure, and the proportion of CO_2 in the flue gases, and it will also be possible to control the temperature and pressure of air in the principal rooms directly from this point. Mr. Barker had designed special instruments and apparatus for this room, and, having been unable in the first instance to induce makers in this country to take up its manufacture, had placed the order in Germany shortly before the war broke out. It then, of course, became essential to order the apparatus here, and we understand that the necessary arrangements have been made, but not without considerable difficulty. Mr. Barker contrasts the apathy of the British manufacturers in this connection with the keenness of the Germans to obtain the order.

We have already referred to the large number of electric heaters and the electric fans. The electrical installation includes also 6,000 Osram lamps, 26 electric lifts, and several motors for miscellaneous purposes, such as knife-cleaning, silver-cleaning, ham-cutting, mincing,

refrigeration, pneumatic tubes, pumps, sewing machines, boot-cleaning, and hair-dressing. The electrical energy is taken from the St. James's & Pall Mall Electric Light Co.'s network at 220 volts D.C. For the heater circuits two pairs of 0'8 sq. in. cables are brought in directly from the Carnaby Street sub-station, and the main distribution board controlling the heater circuits is in a separate chamber in one of the sub-basements. The board is 30 ft. long, and has 60 pairs of cartridge fuses, and 54 pairs of 19/16 cables lead to the distribution boards on the various floors; there are six distribution boards on each floor.

For the lighting and power two pairs of still

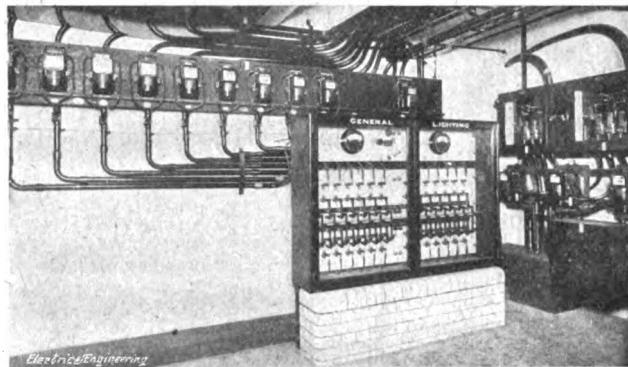

FIG. 4.—ONE OF THE MAIN LIGHTING BOARDS AND THE SUPPLY COMPANY'S BOARD.

larger cable, viz., 1'2 sq. in., are led in, one being on the Supply Co.'s special "theatre" main with its large battery reserve. The two pairs of mains terminate in separate switchrooms, and the two bus-bars in which the two terminate are connected in parallel through a circuit-breaker, so that in the event of the failure of the supply from one pair of mains the current is automatically cut off from that side, and, after the link of the defective side has been removed, the circuit-breaker can then be replaced and the whole load thrown on the opposite side. The lighting of the building is divided equally over the two mains, and each half is again divided, as the circuits to

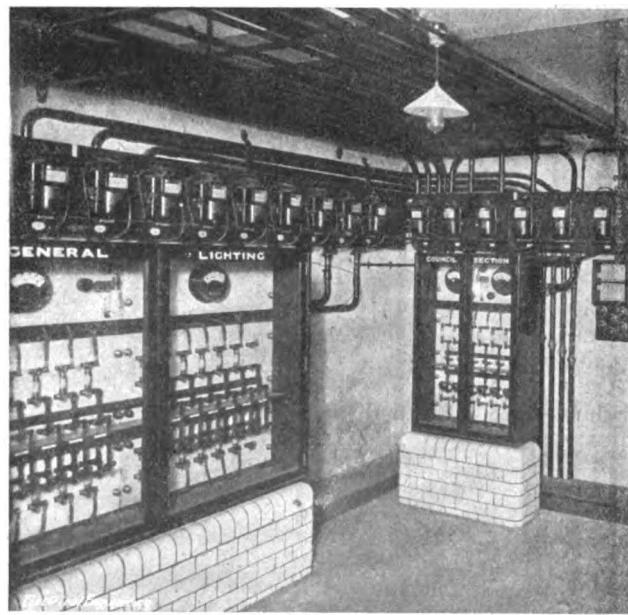

FIG. 5.—THE OTHER MAIN LIGHTING BOARD AND ONE OF THE "POLICE" BOARDS.

the public rooms, corridors, &c., are on "L.C.C." or "Police" boards connected directly to the Company's supply links, and so independent of the other lighting circuits. Thus half the lamps in every public portion of the building are on the theatre main and half on the other, and there is no danger of panic from a supply failure. The power circuits are divided over the two mains also. Fig. 4 shows one of the main lighting switchboards and the Supply Company's main board on the right; Fig. 5 shows the other main lighting board and one of the "Police" boards.

(To be concluded.)

THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

THE Annual General Meeting was held at the Institution of Electrical Engineers on Thursday and Friday, June 17th and 18th. Mr. A. C. Cramb, Acting-President, took the chair.

The CHAIRMAN, in opening the proceedings, said :—"When we assembled in Birmingham last summer for the 1914 Convention we little thought that within a few weeks this country would be engaged in this most terrible war. It is inevitable, of course, that our thoughts and energies must be, to a very considerable extent, occupied with the carrying on of the war and doing all we can to push it forward to a successful conclusion. It has also had certain results on the work of this Association. Firstly, your President, Major Richardson, was called up for active service early in the autumn, and it was found that he would not be able to take part in the deliberations of the Council; your Council appointed me as Acting-Chairman in Major Richardson's place in his absence. At the end of the year, when it became evident that the war would not be over by the summer, the Council had to consider what course should be adopted with regard to holding the Annual Convention this summer. After careful consideration, it was decided that as by the bye-laws of the Association we have to have an annual meeting each year, a meeting should be held in London, but that all social engagements and visits on this occasion should not take place, and further that the visitors' list should not be issued. I feel sure that this decision will meet with your approval in the circumstances. With regard to visitors, the co-opted members of the Vehicle Committee and Development Committee have been invited to take part in the discussions to-day, and I think I ought to take this opportunity on your behalf of thanking these gentlemen for so kindly taking part in the work of these two Committees, and giving their valuable time and experience to furthering the objects for which these two Committees have been established."

The report, given in slightly abbreviated form below, was then presented, the authors explaining, in an introductory note, that, had it not been for circumstances arising out of the war, the review of what had been done by the stations having a "point-five" tariff would have been more complete.

THE PRACTICAL RESULT OF THE POINT-FIVE TARIFF

By A. S. BLACKMAN (*Chief Electrical Engineer, Sunderland*) and THOS. ROLES (*Chief Electrical Engineer, Bradford*).

The following is a list, in chronological order, of the undertakings which have adopted the "Point-Five" Tariff, with the dates upon which it was put into force :—

Poplar (1909), Southampton (1910), Luton (1910), Bradford (1910), Sunderland (1912), Barnes (1912), St. Marylebone (1912), York (1912), Carlisle (1912), Wrexham (1913), Accrington (1913), Sheffield (1913), West Hartlepool (1913), West Ham (1913), Wolverhampton (1913), Ilford (1914), Blackpool (1914), Wakefield (1914), Worcester (1914), Ipswich (1914), Leeds (1915), Chester (1915).

To the Poplar electricity undertaking belongs the honour of being the first to adopt such a tariff, in Feb., 1909, although this fact was not generally known until the formation of "The Point-Fives" Association. The fixed charge at Poplar is varied in accordance with the kw. installed for lighting, heating, cooking, &c. [see a Paper by Mr. H. Bowden (*ELECTRICAL ENGINEERING*, Vol. X., p. 363, June 25th, 1914)], and includes a service charge, and, in some cases, charges for the hire of wiring and consuming devices. Southampton makes the granting of a halfpenny rate for heating and cooking conditional upon the consumer installing a certain minimum number of lights charged at ordinary lighting rates. Luton supplies current for heating and cooking purposes at a flat rate of one-halfpenny per unit without any fixed charge. Bradford confines its Point-Five Tariff to domestic premises, and bases it on the "Norwich" or rateable value system, and practically the whole of the undertakings which have since become converts to the Point-Five principle have adopted this system.

So far as the writers are aware, the two methods cited above of arriving at the fixed charge are the only ones which have been adopted, and the difference between these methods is but one of convenience in the working of the tariff. The fixed charge per kw. is more strictly correct in individual cases, whereas the apportionment upon the size of the house

is an average result which has been found to be a sufficiently close estimate for all practical purposes, and to possess the advantage of uniformity and simplicity; any other readily available basis might be adopted, as, for instance, the cubical capacity of the premises or the total floor area. In most towns in which a Point-Five Tariff, based on the rateable value system, has been instituted, it is restricted to private houses, as it does not so readily lend itself to the more widely varying conditions of other classes of supply. The percentage of the net rateable value decided upon varies, in different towns, between 10 and 15 per cent. per annum, the amount generally being apportioned between the four quarters of the year, sometimes equally and sometimes in approximate proportion to the lighting hours, as, for instance, one-third for each of the two winter quarters and one-sixth for each of the two summer quarters. In Sunderland the percentage is varied between 10 per cent. for a house rated at £30, to 15 per cent. for a house rated at £70 and upwards, because a large house generally furnishes the worse load factor.

Both writers have obtained their experience under the rateable value system, but it does not follow that the system would be equally successful in other towns. Both in Bradford and Sunderland the tariff has been left to justify itself, and no scheme of hiring out heating and cooking apparatus is in existence.

A discretion should be exercised in favour of the consumer who, in consequence of living in a house with an abnormal amount of ground attached to it, is rated out of proportion to the size of the house. In Sunderland the Rating Department have simply been asked to say how much of the rateable value could properly be apportioned to the excess of ground over and above a normal allowance, and such amount has been deducted in fixing the charge. In Bradford, on the other hand, the Rating Authorities, when approached, have only deducted a sum from the total equal to the rateable value of the surrounding land as it would be assessed if used for agricultural purposes, and state that they cannot say what increased value can be put upon the land by reason of its being attached to the house. It follows, therefore, that a reduction made on these lines is insufficient, and if, therefore, cases arise in which this point has to be decided, the practice adopted will probably be to base the fixed charge on what is being paid for houses of similar size with a normal allowance of land.

A marked advantage of the rateable value basis is the facility with which an accurate estimate of a consumer's bill can be prepared; a wide error may be made in assuming the number of units, and the estimate still remain reasonably correct. This has been found very useful to the canvassers in towns where a cheap supply of gas has to be competed against.

Numerous other advantages have attended the adoption of a Point-Five Tariff based on the rateable value system :

Under the ordinary flat rate for lighting purposes residential consumers often only introduced electric light into the best rooms, leaving the servants' quarters, &c., which possess a better load factor, illuminated by gas. On the rateable value basis, however, once the fixed charge is assessed, all current required for lighting, as well as for heating and cooking purposes, is supplied at the low price of one-halfpenny per unit, and consumers, therefore, light the whole of their premises electrically. Carelessness in leaving lights burning unnecessarily does not unduly inflate the accounts. Moreover, under a flat rate the lighting of most houses compared unfavourably with that of houses illuminated by gas, especially when the mantles were kept in good condition, for, on the score of economy, lamps of only small candle-power were generally in use. The low charge per unit on the rateable value system has resulted in consumers using lamps of considerably higher candle-power. It is now usually quite easy to determine whether or not a house is on the Point-Five Tariff by the brilliancy of the light proceeding from the windows. It may, of course, be argued that the additional maximum demand caused by this increase of light must adversely affect the supply undertaking. Against this must be put the fact that, owing to the houses being almost invariably wired throughout, the diversity factor of the installations is higher, which tends greatly to increase the load factor of this class of supply.

No additional charges can be made against the increased amount of lighting on account of services or distribution mains, as the cables used for these purposes are generally standardised to two or three sizes, and the cost of trenching, cutting away of walls, &c., is practically independent of the size of cable used. The additional expenses to the under-

taking consist of the cost of increasing the capacity of the generating plant—which can now be done at far cheaper rates than in the days when the flat rate for lighting purposes was decided upon—and the provision of extra feeder cables. No additional management charges can be debited against the extra lights, as whatever the size of the installation the cost of service inspection, meter reading, rendering of accounts, and general management of the undertaking is practically the same.

It is, of course, possible that the increased capital expenditure incurred on new plant and feeders causes a reduction in the profits, but the writers' experience is that any such reduction from a limited number of consumers is soon far more than counter-balanced by the profits derived from the additional consumers gained by reason of the excellent advertisement of the improved lighting. In both Bradford and Sunderland it has been found that the majority of new domestic consumers adopt the rateable value tariff; houses are, as a rule, wired from cellar to attic; the domestic load factor has improved; the illumination of rooms has in almost every case been considerably increased; and no complaints are now received as to the inefficiency of electric lighting as compared with lighting by means of gas. Since current has been supplied at one-halfpenny per unit, not only has the number of electric heaters increased to a tremendous extent, but the capacity of the individual heaters has also increased, so that in several Point-Five towns the 3 kw. radiator has become a standard. The air temperature of the rooms is kept practically constant throughout, and the occupants are under no necessity to remain within the direct rays of the heaters.

From the point of view of the preparation of this Paper it is unfortunate that the electricity supply undertakings under the management of the writers are both situated in industrial towns, so that the house supply load is not of chief importance. In Bradford the units sold to private houses are only 8 per cent. of the total sales, and in Sunderland 2·6 per cent.

Bradford Results.

At December 31st last, 1,298 private house consumers were connected to the supply, whereas prior to the introduction of this method of charging on July 1st, 1910, the number of such consumers was but 511, representing the result of nearly twenty-one years' working. Thus, during the 4½ years the Point-Five Tariff has been in force, the number of domestic consumers has increased by over 150 per cent. More than half of these consumers have elected to be charged on the special rate, the houses being in practically all cases electrically lighted throughout. Owing to changes of tenancy and alterations in other conditions, the comparison given below relates to only 138 of the consumers changed over, the periods covered being the year prior to the introduction of the Point-Five Tariff and the year ended December 31st, 1914.

Based on the total kw. installed, the average load factor of the 138 consumers increased from 3·38 to 4·34 per cent. The units sold increased from 93,880 to 182,872, the revenue decreased from £1,566 to £1,358, and the average price from 3·98d. to 1·78d. per unit.

The following table applies to consumers supplied under the flat rate of 4d. per unit and under the Point-Five Tariff respectively, the comparison applying to all domestic consumers connected for the complete twelve months ended December 31st last:

| Tariff. | Number of Consumers. | Average | | | Average revenue per house. £ s. d. |
|---------|----------------------|-------------------|----------------------------|------------------------|------------------------------------|
| | | Total units sold. | number of units per house. | Total revenue. £ s. d. | |
| 4 | 340 | 124,742 | 367 | 2,005 | 5 18 0 |
| 0·5 | 566 | 612,502 | 1,082 | 4,312 | 7 12 4 |

A comparison of the diversity factor in the residential areas shows an increase from 2·65 for the year ended June 30th, 1910, to 2·94 for year ended December 31st, 1914, but since the introduction of the Point-Five Tariff a considerable amount of heating apparatus has been connected in private houses without the Electricity Department being notified, so that the diversity factor is actually undoubtedly greater than 2·94. The kw. installed from which these diversity factors are calculated were 420 at June 30th, 1910, and were almost exclusively for lighting. The number of consumers affected was 233, making an average of 1·8 kw. per house. At December 31st, 1914, the consuming devices in connection with the installations in these areas had increased to 853 kw., and the number of consumers to 367, giving an average of 2·32 kw. per house. Of the 853 kw., 545 were for lighting and 308 for heating and cooking purposes, the average per house being 1·48 and 0·84 respectively.

The annual percentage of the rateable value debited to a

consumer in Bradford adopting the Point-Five Tariff is 15, and it is estimated that this, coupled with a charge of one halfpenny per unit, brings in a revenue equivalent to what would be earned for an average supply of current for lighting purposes at a flat rate of 4d. All energy required for heating and cooking purposes is thus obtained at the halfpenny rate.

Although in Bradford domestic consumers have not been approached individually for the purpose of explaining the advantages of changing over to the Point-Five Tariff, more than half have elected to be charged on the latter system, and have introduced heating or cooking apparatus. This is all the more remarkable because no general attempt has been made to induce consumers to instal heating and cooking apparatus, the staff of the business-development department having been fully occupied in dealing with power supplies.

In addition to this, an agreement has been in existence between the Gas and Electricity Departments that in thoroughfares in which electricity mains are already laid the Electricity Department's canvassers shall not call upon gas consumers with a view to persuading them to take an electricity supply. Furthermore, the Gas Department have been exceedingly active during the past few years in advocating the use of gas for heating and cooking purposes.

A letter from Mr. P. Collinson, the Honorary Secretary of the Bradford Branch of the Electrical Contractors' Association, quoted in the Paper, expresses decided approval of the Point-Five or "Domestic" tariff.

Sunderland Results.

At the introduction of the Point-Five Tariff there were 337 private houses connected to the supply, the majority partially lighted only, as the result of sixteen years' working. Since the tariff was introduced on January 1st, 1912, three years' working has resulted in 162 more private houses being connected; 100 of these elected to be put on the Point-Five Tariff and are lighted throughout, and 62 upon a flat rate of 3·6d. per unit. Of the 337 houses that were on the supply at January 1st, 1912, 105 have changed over from the flat rate to the Point-Five Tariff, and of these 87 have, owing to there being no change of tenancy, been taken for the following comparison, the periods being the year preceding and the year following the adoption of the Point-Five Tariff.

The average of consumers' load factor on kw. installed increased from 2·44 per cent. to 4·05 per cent. The units sold increased from 44,827 to 93,327; the revenue decreased from £672 to £616, and the average price from 3·6d. to 1·58d.

For the purposes of comparison it must be remembered that the units and money values under the old tariff refer almost entirely to carbon lamp conditions. Our experience with pure lighting installations that have remained upon our mains unaltered over a term of years, save for the transition from carbon to metal filament lamps, shows that for purposes of comparison under modern conditions the average units consumed per house under the old tariff might be corrected to 354 instead of 512, and the average revenue per house £5 5s. 9d., instead of £7 14s. 5d. Making this adjustment, the following comparison is arrived at:

| Tariff. | Number of Consumers. | Total units sold. | number of units per house. | Average revenue per house. £ s. d. | |
|---------|----------------------|-------------------|----------------------------|------------------------------------|------------------------------------|
| | | | | Total revenue. £ s. d. | Average revenue per house. £ s. d. |
| 3·6 | 212 | 75,032 | 354 | 1,121 | 5 5 9 |
| 0·5 | 286 | 298,563 | 1,044 | 1,803 | 6 6 11 |

The average size of the houses in these two groups is about the same, so that the heavier unit consumption under the Point-Five Tariff is in no way attributable to larger houses.

The maximum load on the residential areas increased from 141 to 227 kw., the kw. installed in private houses from 461 to 1,152 kw., and the corresponding diversity factor from 3·25 to 5. In the earlier period, the 461 kw. connected, was almost exclusively for lighting, averaging 1·36 kw. per consumer; in the latter period the corresponding figures were 650 kw. (1·3 per consumer) for lighting, and 502 kw. (1·09 per consumer) for heating and cooking.

An interesting set of tables, compiled from information obtained from "point-five" stations, was attached to the Paper. In thirteen of the seventeen stations referred to in the tables the rateable value system is adopted for the fixed charge, the percentages varying from 10 to 15 per cent., and some of them introducing a sliding scale. In York, the tariff is not of the simple "point-five" order; the fixed charge is 10 per cent. of the rateable value, and the first units consumed are charged at 1d. up to 75 per cent. of the fixed charge and then at 1d. St. Marylebone calculates the fixed charge at £18 13s. 4d. per kw. of maximum demand for lighting, assuming the maximum demand to be 70 per cent. of the watts installed, "less convenience lights." In Southampton for the period to which the returns apply no fixed charge was made, the Point-Five Tariff being "flat."

The load factors on networks supplying residential neighbour-

hoods show good increases, since the introduction of the Point-Five Tariff, the records being held by St. Marylebone for an increase from 16·9 to 21·4 per cent., Wrexham from 17·3 to 20·9 per cent., and Sunderland from 11·46 to 18·76 per cent. These relate to the whole load on these networks, and not merely to those consumers who have been changed over to the new tariff. A comparison of the number of units per house per annum on the old tariff with the number per house on the new tariff makes it clear that the consumers who have adopted the latter understand its import. Thus in Wrexham 43 houses consume on an average 24,234 units each under the old tariff, and 45 houses an average of 44,383 units each per annum under the new tariff. In Bradford the 340 houses on the old tariff consume an average of 367 units each per year, and the 566 on the new tariff an average of 1,082. At Blackpool only twelve houses have so far adopted the Point-Five Tariff and consume an average of 4,280 units each per annum, while those on the alternative tariff, numbering 2,858, consume on an average 700 units. In reply to a question whether any difficulty has been experienced owing to the increased load on the mains, seven out of fifteen stations say "no," and two reply that slight difficulties have been experienced, but West Ham reports that several cooking consumers have been the cause of expensive mains extensions.

Undertakings having powers to hire out cooking and heating apparatus have been particularly successful with the extensions of their load in this direction, although we note that the rental charge is sometimes a higher percentage of the capital cost. Carlisle bases it at 20 per cent., St. Marylebone 30 to 35 per cent., Southampton 25 per cent., West Ham 20 per cent., Wolverhampton at an average of 15 per cent., and York stands alone at 10 per cent.

The last table of the series relates to Southampton, the town with the flat Point-Five Tariff. From March 31st, 1910, to March 31st, 1915, the total connections increased from 2,759 to 8,085 kw., but the increase in the diversity factor was such that the maximum load increased only from 1,670 to 3,091, and the increase in units sold from 1,622,559 to 5,159,671 shows that the load factor also improved greatly. It is interesting to note also that, out of the 5,159,671 units sold last year, 1,290,442 were for heating and cooking, while in 1909-10 the proportion was only 13,361 to 1,622,559.

The Paper was read in abstract by Mr. Roles, after which the following remarks were added by Mr. Blackman.

Mr. BLACKMAN, referring to the great reduction in the average price per unit resulting from the point-five tariff, said that so far as he was personally concerned, it had not been his ambition to sell electricity exceedingly cheap; it had been very largely a question of either reducing the rates or else losing the business to competitive illuminants and methods of heating. He had before him a rough estimate of the cost of supplying the house load in Sunderland. These figures were based upon existing plant, which carried with it very heavy capital charges in comparison with what could be done in extensions to-day, so that if he could make out a case under existing conditions he had a very good case indeed when it came to future extensions. The annual charges for interest and sinking fund upon the works plant in Sunderland amounted to £1 9s. 2d. per kw. per annum, and taking a diversity factor of 20 per cent. this gave an annual charge of 1s. 5½d. for works plant to meet this domestic load. The extra high tension feeders and sub-station equipment worked out to 11s. 7d., and taking a diversity factor of one in ten, this gave 1s. 2d. per annum. With regard to low tension feeders and networks, which he had gone into very carefully by putting demand indicators in pits controlling certain areas, he took a diversity factor of one-fifth which gave 10s. 4d. That was the heaviest item, and the total came to 12s. 11d. annual charges per kw. Electricity on a 18 per cent. load factor was at present being turned out at 0·13d. per unit, and this gave a total cost per unit of 0·247d., say a farthing. So far from considering that he was on his defence in making out a good case in supplying at ½d. per unit, he was absolutely convinced that ½d. was no good in the northern towns, at any rate for heating load. It was all right for cooking, but for heating it was altogether too expensive, and in the development of the Point-Five tariff there were two alternatives. One would be to keep the fixed charge as at present and supply, in the case of a £40 a year house, the first three thousand units per annum at ½d. and all additional units at ¼d.; and the other alternative would be to give the consumer the option of paying a higher fixed charge, and supplying the whole of the units at ¼d. So far as he was concerned the adoption of one of these two methods was likely to be the trend of events.

Discussion.

Mr. G. WILKINSON (Chief Electrical Engineer, Harrogate) regretted that the Paper should have been presented by two members whose proportion of private residence consumers was very small. At Bradford and also at Sunderland there had been an increase in sales in the order of 100 per cent., but a drop in revenue. If these had been the only towns given in the Paper it would be very depressing indeed, but the tables

at the end showed that the revenue from other towns had substantially increased at the same time as the sales. At Harrogate they had to live largely upon residence business, and he had analysed no less than 918 private residence accounts which were supplied at 6d. and 2d. On this basis these private houses produced £5,702, but taking the Point-Five tariff and a 15 per cent. rateable value, this revenue would have increased to the substantial sum of £7,572, or say £7,000 after allowing for the grounds belonging to the houses. This showed that a rateable value system might be a really sound proposition. There was no doubt, however, that the consumer who would not benefit by it would not take advantage of it, and therefore, for the time being, the undertaking must suffer. It would be counterbalanced ultimately by the extra current taken, and the temporary slump might be largely guarded against if a condition were incorporated that anybody adopting the tariff must put a certain percentage of other devices into their premises before they would qualify. With regard to the increasing use of radiators, there was very little doubt that an immense amount of damage had been done by putting in radiators which were much too small for their rooms. It was satisfactory to know that in the Point-Five districts radiators were being very much increased in power, but this necessarily entailed some method of regulation. It was absurd to expect people to pay ½d. per unit for water heating. It was possible to obtain apparatus which would give a 100 per cent. load factor and consume ½ kw. continuously for which supply could well be given at ½d. per unit, or 4d. per day. This would compare well with other methods. It should provide a household with sixty-five gallons of water per day raised from 50° to 100° F., and under normal conditions in a small household he contended that this was ample. In this matter of the electrical equipment of the household, a factor which should be put in the equation was the saving of domestic labour.

Councillor SYMONDS (Hereford) said that it was an exceedingly dangerous doctrine to put forward without reservation that it was a good thing to cultivate a heating and cooking load. In Hereford, for instance, the upper-class residential houses were in districts quite separate from each other and at considerable distances from the centre of supply. Again, these houses were all late dinner houses; the cooking load would come on top of the lighting peak. The cable which supplied his own house ran 2,400 yards from the nearest feeding point. There were forty-one consumers on that cable, and if all were to take current for cooking it would be necessary to treble the cable, and in nearly all cases to double the services. The Gas Department at Hereford had 2,500 cookers and, in a town of only 22,000 inhabitants, 600 gas fires, and therefore the Electricity Department would have to do better than making an ordinary working profit before it could justify to the Council any such action. In addition to this, such districts were liable to grave difficulties in maintaining the pressure. If he were provided with a frying-pan, a rasher of bacon and a stop watch, he would undertake to tell the pressure at the station within 3 per cent. of accuracy. It had happened during the past winter that the ruler of his house had told him that the volts at the station were down because she could not cook the breakfast, and by checking them on the recording meter he had found that the pressure was down 7 volts. Councillor Symonds then proceeded to criticise the Point-Five tariff. At Bradford, where the lighting load was insignificant, it did not so much matter that the consumers who had taken this system up had been presented with 89,000 units, and in addition had been given a cash bonus of £177, but it really did not strike him as business. Only one place was apparently realising a profit, and that was Marylebone, which obtained 1·6d. per unit, and it was significant that Marylebone was the only one which had not adopted the rateable value system, but had the kw. demand system. With the rateable value system they would be charged with giving undue preference. He had taken two Hereford consumers as an example who at present each paid about £14 a year. On the basis of 15 per cent. on rateable value and ½d. per unit, one would pay £8 and the other £20. The only plea raised for rateable value was that they must have something the consumer could understand. He differed. What was wanted was something the consumer thought he understood, and he would undertake to make any consumer think he understood the maximum demand system within five minutes. Lastly, a tariff should apply to all consumers alike, and for this reason he was in favour of the kw. demand charge and so much per unit, as this could be applied to business premises just as well as to private premises.

Mr. C. H. WORDINGHAM said that when, in 1893, the Hopkinson system of charging was introduced in Whitehaven and Manchester the argument which he found was effectual was, "wait and see when your bill comes in, and you will find how much less it is on this mysterious method than on the flat rate." His words were usually justified. He did not find the most difficult people to be convinced to be the consumers; he found the members of the Committee were much more thick-headed. People were now re-discovering the Hopkinson system. Not many years ago they found men like Handcock and Dykes re-discovering it with a tremendous flourish of trumpets as a great novelty; they seemed to think it had something to do.

with metal filament lamps. And now the Point-Five Association had re-discovered it, although they had mutilated it worse than anybody else had. He disagreed entirely with the rateable value system of charging. He contended that it was essential to have fixed charges which bore a proper proportion to what the fixed charges cost, and there must be a revenue which had a proper proportion to what the running charges cost. Then the fixed charge per kw. plus a charge per unit was the only sound system of charge which should be adopted in all towns of the kingdom. He did not believe for one moment that it was possible to heat water, as Mr. Wilkinson had suggested, economically in sufficient quantities for ordinary domestic supply, and he firmly believed that the cause of electric supply was damaged by statements of that kind. He did not believe that in practice it could be done, and it was a great mistake to try to do it, or to say it could be done.

Mr. W. W. LACKIE (Chief Electrical Engineer, Glasgow) said that the report bore out what was shown by the Paper read at last year's Convention by Mr. Bowden, viz., that energy was not supplied at 0'5d., but rather at something like 1'5d. per unit. In both Sunderland and Bradford he noticed that the effect of the introduction of the Point-Five tariff had been to reduce the revenue per house. In fixing the Glasgow domestic tariff his main endeavour had been to see that the revenue per house was increased and not diminished. If a consumer was paying £5 per annum for lighting his house, he got excess units over this at 3d. without the necessity of having an additional meter and separate wiring. Their charge for a £40 house was 3d. per unit for the first 200 units per annum and 3d. thereafter. The 200 units were allocated *pro rata* to hours of darkness over six two-monthly periods. In his own house the charge was 300 units at 3d. and all over at 3d. The total annual consumption was about 1,500 units, giving an average price of 1'2d. per unit. There were in Glasgow 10,000 domestic consumers, and 2,300 of these had adopted the proposal put forward and had taken 600,000 units for heating and cooking purposes. The 2,300 consumers who had installed heating and cooking apparatus had increased their domestic consumption from 500,000 to 1,100,000 units. The principal matter of interest from a domestic point of view in Glasgow, however, was that fully a year ago an enterprising builder started the erection of a number of houses and equipped them electrically throughout. There was one ventilator to each house in place of a chimney. Heating, cooking, and lighting were all done entirely electrically. No coal or other fuel was allowed inside any of these houses. One of the houses had been occupied for a year by the builder himself. The units used were 16,000, and the total bill £51 8s. The average price per unit worked out at 0'77d. This was for a house of five apartments, and the occupier expressed himself as being quite satisfied. Some years ago the question of power factors, load factors, and diversity factors was looked into, and in a town near Glasgow, which is entirely residential, it was found that the ratio of maximum demand on the station to lamps installed in the houses was 1 : 5. A large block of tenements in the West End of Glasgow was taken, and there it was found that the ratio of maximum demand on the feeders supplying the block to the lamps installed was 1 : 6. This, he did not think, confirmed the diversity factors of 2'6 and 2'2 given in the Paper.

Mr. H. W. BOWDEN (Borough Electrical Engineer, Poplar) said he was a great advocate of the Point-Five system, and thought it was absolutely right, but joined issue with the authors upon the question of assessment. It seemed to him that it was no more difficult to arrive at a true fixed charge, taking the amount of radiators, heaters, lamps, etc., installed, as leaving the whole thing to another department, who knew nothing at all about the assessment on an electrical basis. The only advantage that the rateable value could claim, in his opinion, over the proper fixed basis, was that of simplicity. He favoured the system described in his Paper last year, and quoted figures to show that its result was increasing profits. Poplar was the only undertaking in the country that had been able to reduce prices since the war broke out; for domestic supply they had reduced the prices practically 25 per cent. During the last two years Poplar had put by a certain amount out of profits, and was now prepared to send out small apparatus, such as fans, irons, and radiators, free of charge in order to create that load. He did not agree with the authors that it would not be necessary to increase the charges on account of services, because when cookers were put in it invariably necessitated larger services, especially if the apparatus were 5 or 7 kw. Up to a point he was inclined to agree that the management would not be increased, but if the thing extended to any large degree there must be increased management charges after a certain period.

Baillie STEVENSON (Edinburgh) said he was not a convert to the Point-Five tariff, and put forward one or two objections to it from a convener's point of view.

Alderman SMITH (Barrow-in-Furness), replying to the criticisms of Councillor Symonds, said that it was not the big houses that came on first for electric cooking, but the middle-sized houses, and the question of increased cost of mains did not apply to them with the same force. The bulk of people in these houses had their dinners at mid-day, and they did

not all have hot dinners on the same day. It was in the smaller houses, where the wife did most of the cooking herself, that electric cooking was more likely to be adopted and appreciated.

Mr. R. A. CHATTOCK (Chief Electrical Engineer, Birmingham) said that industrial towns began with a lighting load and put forward low tariffs for power supply. They were criticised, but the low power rates had justified themselves. In some of these industrial towns the lighting supply was, in fact, becoming a by-product, and they could afford to charge low rates for lighting, and attract a heating and cooking load in the same way that they built up their power business. But residential towns must feel their way very gingerly, or else they might be faced with a loss for some years.

Mr. W. H. COOKE (Chief Electrical Engineer, Luton) said he did not believe in the rateable value system; it was not equitable. The rateable value of a house had nothing whatever to do with the consumption of electricity in that house. In Luton there was a simple flat rate of 3d. per unit for heating and cooking purposes. He had considered, first, whether heating and cooking would stand a higher charge, and his conclusion was that it would not. Moreover, he had found that 3d. would very well include capital charges. One great objection he had to the rateable-value system was that it could not be supplied to business premises, and the heating load of business premises was equally as valuable as the heating and cooking load in domestic premises. In the returns given in the paper, the largest number of units given for domestic purposes was 185,000, at Bradford. In Luton, which was a very much smaller town in population than Bradford, they had sold about that same number for domestic purposes, and, in addition, nearly half a million units for business premises. This did not refer to industrial heating, but power for heating business premises and offices, and this load was obtained because it was supplied at 3d. per unit. Last year there was a considerable increase in the output; 85 per cent. of that increase was due to the units which were sold at and under 3d. per unit, and they had made very much larger net profits than were made in previous years. It was absolutely essential to have a hire system in operation for heating and cooking purposes, because of the high price of the apparatus.

Councillor CROWTHER (Sheffield) said he was a strong supporter of the rateable-value system. For something like seven years he was on a flat rate of 4d. for all purposes, but at the first opportunity he went over to the rateable-value system. Immediately his all-round cost went down from 4d. to something like 1d., and taking the average of a number of houses in large towns with a rateable value of £25, the cost worked out to about 1d. per unit. For houses of £30 rateable value, it went up to 1d., and at £40 it went to 1d., so that the larger the house the higher the cost. This, however, was an absolutely fair principle, and it had been recognised for several years in connection with water supply. Some allowance should be made in those cases where large grounds were attached to the houses.

Mr. A. NICHOLS MOORE (Chief Electrical Engineer, Newport, Mon.) said that at Cardiff last year, with a 1d. flat rate for heating and cooking, the revenue was increased from £615 to £1,083, and in Newport the units for these purposes had been increased from 77,000 to 166,000, and the revenue from £280 to £692. The total number of heaters had jumped from a matter of dozens to 300, and with cookers they had now made a modest start of 26. So much for the question that it was impossible to do anything except with a 3d. tariff. If the average price obtained was rapidly decreasing, and the percentage of the working costs to the total receipts were shown to be a steadily increasing quantity—with capital expenditure going on all the time—then, with the percentage of gross profit also rapidly decreasing as a sequence, there was something wrong about the financial condition of such an undertaking. He had been led to that thought by Mr. Roles' figures; his revenue had actually decreased by £208, and he had actually spent £100 in getting those units on the basis of 3d. per unit, making a total adverse balance of £308. Taking Luton, Southampton, York, Carlisle, and Marylebone, the average decrease in price received since the adoption of the Point-Five tariff was 39 per cent. The percentage of works costs to revenue received had risen by 13'5 per cent., whilst the percentage of gross profits to total revenue, which was only 42 per cent. originally, had dropped by 10'5 per cent. Against these he put the case of Norwich, Nottingham, Leicester, Brighton, and Mansfield, which had not adopted the Point-Five tariff. The average decrease in price during the same period of these undertakings was only 8'5 per cent., the percentage of works costs to revenue had only increased by 5'5 per cent., but the percentage of gross profit to total revenue had only decreased by 3 per cent., as against 10'5 per cent. in the other instances.

Mr. F. M. LONG (Chief Electrical Engineer, Norwich) said that with coal costs at 0'17d. per unit as at Sheffield, it was easy to see that current could be supplied at 3d. per unit, but when the coal was costing 0'56d. per unit, as at Ilford, it was quite a different matter, and there should be some explanation as to how a Point-Five tariff was justified in such cases as that.

Councillor JONES (Kilmarnock) said that in Kilmarnock they

had been working on the rateable-value system, but their experience had not justified their original firm belief in it.

Mr. Roles and Mr. Blackman then replied briefly to the discussion, Mr. Blackman remarking that it had rather gone to exemplify the truth of the old saying that any case could be killed with talk.

THE USE OF ELECTRIC VEHICLES IN MUNICIPAL SERVICE

By F. AYTON (Hon. Secretary to the Electric Vehicle Committee.)

THIS Paper is a report presented by the Electric Vehicle Committee. It is remarked at the outset that there could hardly be conceived a more suitable field for the employment of the electric battery vehicle than that connected with municipal service, because the work lies entirely within the sphere of short-distance haulage at moderate speeds. The mileage capacity per charge, i.e., 35 to 45 for the heavier vehicles, is sufficient for practically every duty which the municipal vehicle has to perform, and, by a midday boosting charge, may be considerably increased. The main reason for urging the adoption of electric vehicles by municipalities is the economy which attends their use in substitution for horse haulage. In support of this contention, attention may be directed to the experience of Glasgow—where the Electricity Department found that their first electric van, of 1-ton capacity, did the work of two horses at a saving in expense and with greater efficiency, while, compared with the petrol van, the electric did the same work with a saving in the neighbourhood of £240 per annum. Other evidence is afforded by the refuse collection trials at Barnes and at Heston and Isleworth, while the case of Calgary, the daily saving, as against horses, by the operation of two electric

a half-ton or one-ton van for delivering meters, transporting materials to the service and mains-laying gangs, and in other like duties. And in the larger undertakings good use may be made of a small electric car for the business rounds of the engineer, the mains superintendent, or the sales manager.

Delivery vans are now in use or on order by the Electric Supply Departments at Glasgow, Edinburgh, Derby, West Ham,

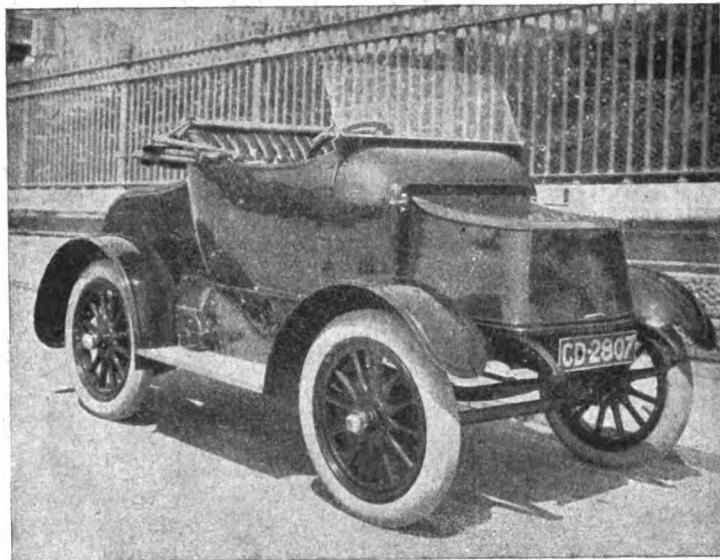

FIG. 2.—THE BRIGHTON ELECTRIC SUPPLY DEPT. ELECTRIC CAR.

Croydon, Blackburn, Bootle, Hereford, Ipswich, Grimsby, Brighton, Wolverhampton, Southampton, Liverpool, and the Borough Councils of St. Marylebone, Stepney, and Poplar. The one-ton Edison van used by the Glasgow Electric Supply Department has been in constant use since August 6th, 1913, and up to April 28th, 1915, had covered a total mileage of 22,284 with an energy consumption of 13,752 units, including battery losses, or 0·62 unit per mile; and the Department has ordered a half-ton and a one and a half-ton vehicle for delivering material from the general store, and a three-tonner for mains work. The vehicle at Brighton is a two-seater car used by the Engineer and Manager of the Electric Supply Department for business purposes. Its speed is about 16 miles per hour on the level; weight, 22½ cwts.; average daily mileage, 25; while the energy consumption is about 0·5 unit per mile input to battery. At 1d. per unit this is only about one halfpenny per mile. The vehicle has run close on 1,000 miles at the time of writing, and, so far, beyond the cost of cleaning, it has cost nothing for maintenance, the tyres showing little or no signs of wear. The battery is of Tudor make. The West Ham Electric Supply Department's one-ton Edison battery vehicle, which took part in the electric vehicle parade, was described and illustrated in our issue of last week.

The St. Marylebone Electric Supply Department van was also

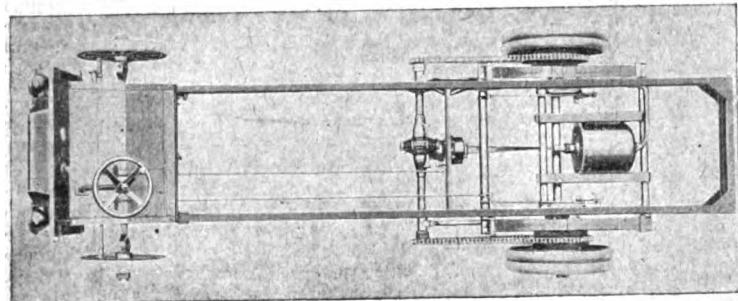

FIG. 1.—TYPICAL ELECTRIC VEHICLE CHASSIS SHOWING THE SIMPLICITY OF THE MECHANISM.

watering and flushing vans, is given as about £5. Outside municipal service we have the case of Harrod's Stores, who run 55 delivery vans, and give as their reason for adopting the electric vans: "We find them cheaper than horses."

The durability of the electric vehicle is such that there is justification for putting the average life of a modern vehicle of good make at not less than ten years. In the United States electric commercial vehicles built twelve years ago are still in daily service. Reliability is another feature, for experience has shown that this type of automobile can keep the road day by day for more days in the year than any other type. The reasons for this are the simplicity of the mechanism, the strong construction, and the fact that any repair or replacement can usually be effected during the night, or in such a short time as not to interfere with the use of the vehicle. The introductory portion of the Paper dwelt further on the hygienic advantages of electric vehicles, the fact that 70,000 are in use in America, and, in the case of municipalities that own electric supply undertakings, there is the important new source of revenue which the general use of electric vehicles in any district will open up, the demand in connection with which need never come on during "peak-load" hours.

The Electric Supply Department.

It is necessary that a department hoping to induce the adoption of the electric vehicle in its territory should itself set the example. Apart from its advertising value and its usefulness for giving demonstrations, the electric vehicle has many other advantages. For breakdown work it is ready to go out at a moment's notice, and is so simple that several of the mains staff may be taught to drive it. There are few undertakings of reasonable size that could not make use of

FIG. 3.—THE ELECTRIC VAN OF THE IPSWICH ELECTRIC SUPPLY DEPARTMENT.

described and illustrated in our columns in connection with the parade.

The vehicle of the Electric Supply Department at Wolver-

hampton is used for delivering goods, as well as to take men and their tools on to jobs. The energy consumption is 0·74 unit per mile input to battery, and the speed about 12 miles per hour. The Department has on order a 2½-ton vehicle for the removal of clinker and ash from the power station. The Ipswich vehicle (Fig. 3) has a total weight of 34½ cwts., a speed on the level of about 12 miles per hour, and an energy input to the battery of about 0·7 unit per mile. The vehicle is used for delivering the goods of the Installation Department, and is also employed by the Mains Department. The vehicle belonging to the Croydon undertaking is a two-seater run-about fitted with an Edison battery. The car is used by both the Distributing Engineer and the Sales Superintendent, and during the five months the expenditure in repairs and general upkeep has been nil. The total mileage covered in this period has been 2,156, or an average of 24 miles per day. The Borough Electrical Engineer, Mr. A. C. Cramb, gives the following costs of operation :—

Running Costs.—Energy (at 1d. per unit), 0·510d.; oil and grease, 0·007d.; washing, cleaning, &c., 0·388d.; tyres (£35 per set for 5,000 miles), 1·660d.; total running costs, 2·565d. per mile.

Depreciation.—Battery (5 years), 1·600d.; vehicle (10 years), 1·620d.; total cost per mile, 5·785 pence per mile.

Besides their use for delivering goods, answering "breakdown" calls, and carrying the supervising officials about, there are other ways in which the electric vehicle may be made use of in the service of electric supply undertakings. They may be fitted with motor-driven winch gear for use in drawing cable into underground conduits; an electrically-operated pump may be fitted for clearing water from manholes, while a telescopic tower ladder can be provided for trimming arc lamps and for overhead work generally. Where a motor winch is provided, the addition of a simple derrick enables the vehicle to be employed in the erection of street lamps and trolley posts. Where the generating station is not provided with rail or water facilities for the direct delivery of coal, so that the latter has to be carted from the railway dépôt or from a wharf, an electric waggon of suitable capacity should soon pay for itself. The same vehicle could be used for carting away ash and clinker. In demonstration work the electric vehicle promises to be a useful aid. By the aid of a flexible cable carried through the front window of the house, from the vehicle standing outside in the roadway, the canvasser will be able to demonstrate the various domestic uses of electricity.

The Collection of House Refuse.

The collection of house refuse is more trying for steam or petrol vehicles on account of the many stops and starts than to the electric vehicle, which possesses a degree of reliability in such work, together with an economy in operation, which are impossible of attainment by any other type, and, when standing, no waste of power is going on.

Another argument in favour of adopting the "electric" when the change is made from horse haulage is the possibility of utilising the horse-vehicle drivers as the drivers of the new vehicles. In some cases the best economy might be obtainable by a combination of horse-drawn vehicles for the

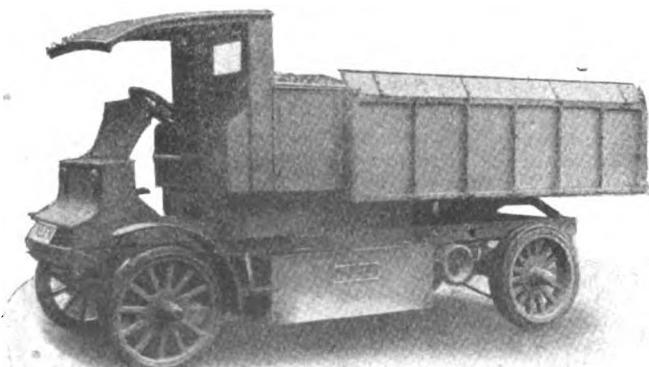

FIG. 4.—AN ELECTRIC TIPPING WAGGON FOR THE COLLECTION OF HOUSE REFUSE.

districts in propinquity to the destructor, with the use of electric vans for the districts further away. An alternative method is the employment for local house-to-house collection of a special type of small electric vehicle, with tipping-box body as illustrated in Fig. 5.

The Urban District Council of Barnes, after a trial of electric

vehicles for refuse collection, has placed an order for four vans. The Surveyor, Mr. G. Bruce Tomes, reports that one electric van would do the same work per week as sixteen horses and carts. The cost of the type of electric van decided upon, with battery and electrically driven tipping gear, is £945. The capacity of the van is 4½ cubic yards, which compares with the 2½ yards of the present cart. As a result of tests, Mr. Tomes found that the cost of operation came out at 19s. 4d. per van per day. The comparable figure for a horse and cart is 11s. per day. Mr. Tomes reported that the replacing of the existing

FIG. 5.—SPECIAL SMALL REFUSE VAN.

horses and carts by four electric vans would, notwithstanding a capital expenditure of £4,000 on the vans and charging plant, result in a saving of at least £400 per annum. A similar trial made by the Surveyor of the Heston and Isleworth Urban District Council resulted in an order for an Edison electric dust van. Experiments were made with electric, steam, and petrol vehicles. It was found that any one of the three waggons could do the same work as previously done by four horses. The purchase costs of the three types of vehicles were: electric, £840; steam, £617; and petrol, £815; the estimated annual costs of working, including capital charges, being given as £333, £338, and £404 respectively. In December last trials were made of the use of electric vehicles for the collection of house refuse in Birmingham, and as a result the Corporation have placed an order for two "Orwell" vans. Dover is another place where electric vehicles are about to be used for the collection of house refuse, the Corporation having decided to order six Edison vans. Each will take the place of three carts and sixteen horses. Electric vehicles have also been used to a considerable extent for refuse collection on the Continent.

Ambulance Work.

By reason of its smooth and silent running, the uniform and jerkless acceleration, the electric is an ideal vehicle for ambulance work in our towns and cities. It has for some time been employed for this purpose by the City of London Corporation, by the Port of London Authority, and the Metropolitan Asylums Board. In addition to advantages of economy, the promptitude with which calls may be answered is as valuable an attribute as in the case of Fire Brigade Service. The simplicity of operation also enable several ordinary attendants to be trained to drive.

In regard to the City Police Ambulances, Captain Sir J. W. Nott-Bower (Commissioner of Police) reports that the cost of working is about 5·1d. per car mile, including expenses such as tyres, necessary repairs to cars, charging of batteries, &c., but excluding wages and rent. Electric ambulances are also in use in the United States. The New York Hospital, for example, has seven such vehicles.

Fire Brigade Work.

Electric battery vehicles have been in use to a considerable extent for fire brigade work. Notable examples of their use are to be found in London and Liverpool; while, up to the outbreak of war, they were known to be employed in several Continental cities, one having no less than 24 in use. Several towns and cities in the United States also employ electrically-propelled fire engines and escapes.

The London Fire Brigade possesses a total of fifteen electrically-propelled vehicles, the oldest having been put into commission in 1911, and Lieutenant-Commander Sladen, R.N. (Chief Officer) recently said :—"Among the advantages of electric vehicles for fire brigade work, we find that they require repairing less frequently, and that the rapidity of turn-out is abso-

lately unequalled by any other form of traction; it is not uncommon at an electric-motor fire station under ordinary service conditions for a turn-out to be effected in 7 or 8 seconds,

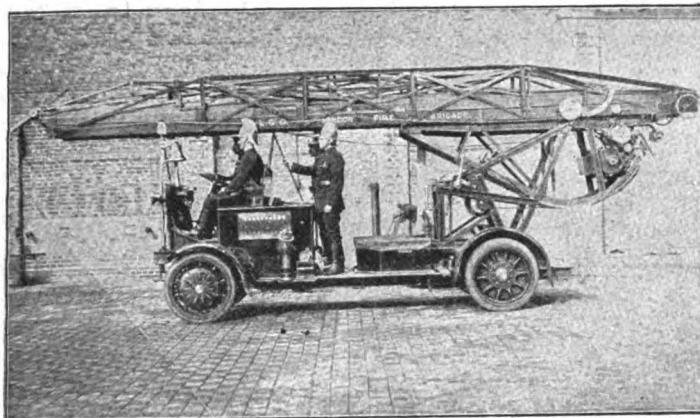

FIG. 6.—ELECTRIC TURNTABLE LADDER, L.C.C. FIRE BRIGADE.

whereas with other forms of motors a good turn-out is perhaps 15 seconds. . . . The maximum speed is at once obtained, whereas with other forms of traction, namely, steam and petrol, a little time has to elapse before things become quite normal."

The Liverpool Brigade has had four electric vehicles, which have given every satisfaction, and cost 2½d. per mile to run.

Reports from American fire departments bear witness to the reliability of electrically-driven engines, even under conditions of heavy snow.

In regard to cost of operation, Lieutenant-Commander Sladen has stated that, in the London Brigade, the electrically-propelled appliances cost, on the average, about 1s. per mile to maintain, not including drivers' wages, capital charges or depreciation, whereas the similar figure for the brigade's petrol vehicles is 1s. 3d. The cost of maintenance of an electric fire-escape and of a petrol fire-escape are about the same, namely, about £150 a year, allowing for interest and depreciation. The annual cost of repairs for an electric escape van that runs about 800 miles per annum is £40, that is allowing for renewals of batteries and so forth. Further information shows that the cost of repairs to accumulators for twelve months worked out at an average price of £22 per vehicle, including a complete renewal of one battery and extensive replacements to three others. The vehicles of the London Brigade can run up to 27 miles per hour on the level, while up a gradient of 1 in 19 the speed is 15 miles per hour. No difficulty has been experienced in converting horse-drawn steam fire-engines and other apparatus, the application of the front wheel drive to which the electric motor so readily lends itself making the problem quite an easy one.

Upkeep and Cleansing of Streets and Roadways.

The electric vehicle is in extensive use on the Continent and in the United States in connection with street cleaning and brushing machines and for watering. One important Continental city having about thirty in use, and the saving stated to result from employing "electrics" in place of horse-drawn vans for this purpose is about £80 per electric van per year. The electric vehicle is also employed for carrying materials used in the making and repair of roadways, and a 3-ton wagon with tipping body has just been put into service for this purpose by the Corporation of Ipswich. It has been suggested that an electrically-driven road roller would be an improvement upon the steam roller. As weight is an essential requirement, a battery of as large a capacity as necessary could be fitted.

The Tramways Department.

There are now three municipal tramway undertakings making use of the electric battery 'bus as an adjunct to their tramway services, i.e., Southend-on-Sea, South Shields, and York.

The South Shields Corporation 'buses have accommodation for 22 passengers, the speed being 12 miles per hour on the level and about 6 miles per hour on gradients of between 1 in 8 and 1 in 10. The energy consumption per mile is under the best conditions about 1·3 units, while the figure runs up to about 2 units per mile when the roads are deep in mud. On a fine day each 'bus will run, if necessary, 50 miles on one charge. A charging station is placed at one terminus, enabling each 'bus to be given a boosting charge several times a day, which enables a fast service to be obtained during the evening without the necessity of charging during the station "peak-load" hours. The 'bus which the Southend Corporation Tramways Department has had in use since June 26th, 1914, is similar to those employed at West Hartlepool. At Southend other 'buses of the petrol and petrol-electric type have also been in use. Mr. Birkett, the Engineer and Manager of the combined electric supply and tramways undertakings, dealing with the running of all three

types, says: "The electric 'bus is the most reliable and free from breakdowns. This is no doubt owing to the simplicity of the mechanism." He gives the actual average cost per 'bus mile (including capital charges) for each type as follows:—Petrol, 8·56d.; petrol-electric, 8·31d.; electric, 7·52d. The consumption of energy on the hilly route is at the rate of 1·55 units per mile, while on a route which is more or less level the figure comes down to 1·1. The 'bus receives a short boost while waiting at one terminus, the boosting current being about 300 amperes. The average speed, including stops, is about nine miles per hour. Battery 'buses are on order for the West Bromwich Corporation and for a company at Loughborough.

The Ilford Council Tramways Departments employ an electric tower wagon, which has now been in service for over twelve months. Although it weighs some three tons, the energy consumption is only a little over a unit per mile. With the exception of the cost of a little distilled water for the battery, no expenditure has been necessary for maintenance during the time the vehicle has been in commission, and there is stated to be no sign of wear upon the tyres. Similar vehicles are in use by, or on order for, the Tramways Departments at Derby and Belfast.

For courtesy in providing the illustrations in the Paper which we have reproduced our thanks are due to Edison Accumulators,

Discussion.

In some additional remarks on his paper (which was not read in full at the meeting), Mr. Ayton pointed out that the present was a very opportune time for putting forward the claims of the electric vehicle, the adoption of which would free the demand on commercial users of petrol vehicles, which were so insistently needed by the military authorities. He also emphasised the fact that the electric vehicle did not require the services of professional chauffeurs, a class which could command high wages, and whose services were urgently needed for military purposes.

Mr. W. W. LACKIE (Chief Electrical Engineer, Glasgow) said that the whole electrical industry in this country was indebted to Mr. Ayton for the manner in which he had taken up the question. There was one use to which the Glasgow Corporation had put their electric vehicle which had not been mentioned, and that was for pressure-testing of plant in a sub-station before the supply was available. The Corporation had a motor generator which could be put inside a one-ton van, and this was taken to a sub-station. The motor was connected

to the battery of the vehicle, and this drove an alternator giving alternating high-tension current at 13,000 volts for testing the 6,600-volt plant. A similar arrangement might be used for the testing of mains. He thought that for practically every purpose except touring, the electric vehicle was superior to vehicles propelled by other means. For ordinary carting purposes, the Glasgow Corporation a few years ago were charged 7s. 6d. per day for a horse and cart, but to-day the cost was 11s. 6d. At 11s. 6d. per day it was costing them £160 per annum for a horse and cart, and with a one-ton van they were easily doing what two horses and carts did for £240 per annum, as against £320, for horse haulage. The Corporation now had had three years' results with a one-ton van, and the results had been so satisfactory that three other vans were ordered. The original one-ton van was equipped with the smallest size of Edison battery, and it was found that with one charge it could do 36 to 40 miles. When they came to order further vans, he took the opportunity of putting in an A6 battery into the one-ton van and putting the A4 battery into a new half-ton van. The Corporation found that 35 miles a day did not meet their average requirements for a one-ton van, and with the A6 battery they could get 60 miles with one charge. The other two vehicles they had ordered were a one-and-a-half-ton lorry and a three-ton lorry. With electricity at 1d. per unit, the probable revenue from electric vehicles might be taken as £20 per annum for a half-ton van to £40 per annum for a three-ton van. The high first cost of the electric vehicle would no doubt be rectified, as it must be if we are to get ahead with its use. The Vehicles Committee had very properly standardised charging plugs and one or two other important details, but he thought that something should be done in the way of standardising the weights and sizes of trucks of different carrying capacities.

Mr. C. H. WORDINGHAM pointed out that there were certain questions which the advocates of electric vehicles would have to answer. Numerous attempts had been made to run trams by means of batteries. The tramcar presented the nearest approach to ideal conditions, but was it possible to point to any instance in which battery-driven trams had been a success? Why was it, he asked, that the present advocates of electric vehicles looked forward with such success to electric vehicles running on ordinary roads, when trams using batteries and running on tramlines had failed? Another point was the necessity for really convincing demonstrations of the merits of these cars in comparison with the sort of car they desired to displace. In conclusion, he referred to the standard plug. The Electric Vehicle Committee had been working in conjunction with the Engineering Standards Committee. The standard specification had not yet been issued, although everything was completed last January, as difficulties had arisen in preparing the gauges. However, these were now supplied, and the specification would be issued very shortly.

Mr. R. A. CHATTOCK (Chief Electrical Engineer, Birmingham) said that the electric vehicle was a vehicle for commercial use in carrying goods and heavy haulage, but he did not suggest it was of use for long distances at present. Mr. Wordingham had criticised the possibilities of the electric vehicle from experience obtained with tramways run by batteries. A tramcar was a very heavy vehicle, and it was hardly fair to assume that, because a tramcar had not run satisfactorily by batteries, but was run satisfactorily from a trolley wire, therefore an electric battery was not the proper thing for an ordinary road vehicle. In America there were upwards of 70,000 battery vehicles running, some heavy and some light. He was glad that reference had been made to the Standards Committee, and was glad to have the opportunity of thanking them for the great assistance they had been to the Electric Vehicle Committee.

Mr. J. W. BEAUCHAMP (Chief Electrical Engineer, West Ham) said that there were four users at present of electric vehicles, with two three-ton, three one-ton, and five half-ton vehicles, in his district. Six of these were repeat orders based on the experience of the first one in each case. The most direct method of pushing the electric vehicle was for the Supply Department to use one. His own experience of a one-ton Edison, in use by the Mains Department, was as follows. In use 87 weeks, an average mileage per day of 17½ had been covered in average running time per day. The consumption of electrical energy was 0·6 unit per mile at 1d. per unit. The revenue from mixed commercial electric vehicles appeared likely to be between £20 and £30 per vehicle per annum. He thought it was very desirable for the moment that the efforts of central station men should first be concentrated on the big users of heavy vehicles.

Mr. G. BRUCE TOMES (Borough Surveyor, Barnes) expressed his satisfaction with the working of the electric vehicles used in his Sanitary Department. They were a great advance on anything he had yet used for the collection of house refuse. Considerable saving had been caused by the speed of the vehicles. With horse vehicles, the travelling took about 6½ hours per day, and the collection 2½ hours per day, but with electric vehicles they were able to collect during 6½ hours a day, whilst the travelling only occupied 2½ hours per day. They had also great advantages in quietness.

Mr. H. S. ELLIS (Tramway Manager, Southampton), referring to the Edison omnibuses which had been put into service by

the South Shields Corporation, said that these were used with success as feeders to the tramway system. They were charged at night time at the car shed, where a motor generator set had been installed, and the current was charged at 1d. per unit provided it was taken between 11 p.m. and 6 a.m. At the end of the route there was a small charging station which was utilised for giving a short boosting charge. The result was that the bus was able to remain in service the whole day long, and travelling from 70 to 80 miles per day. For general purposes, he thought that high capital cost and low speed were against electric vehicles, but hoped that both these disadvantages would be got over. The advantage of the electric vehicle was that it was cheap to run, very easy to handle, and the maintenance costs as low as they could possibly be made.

Mr. J. W. HAME (Chief Electrical Engineer and Tramway Manager, York) said the Corporation had four electric omnibuses fitted with Edison accumulators, the first of which was put into service during February. The buses had run up to date 13,600 miles, and the current consumption was 1·1 unit per mile. If the Corporation had purchased petrol buses, the fuel bill for an equivalent week on the same service, which at present amounted to 1,260 miles a week, would be about £509 a year, against £365 for electricity at 1d. per unit. The buses themselves were popular, and there had been extremely little trouble, and, so far as electrical equipment was concerned, no trouble whatever.

Mr. C. E. COOPER (Wimbledon) said that in municipal work there was a unique opening for the electrically-propelled vehicle, especially now that horses and horse labour was so dear, but complained that, so far, there was a lack of properly designed vehicles to suit the municipal authorities in this country.

Alderman LLOYD (Bristol) was also keenly interested in this matter, and was quite satisfied that the future of traction for municipal work was the electric vehicle.

Mr. H. WEBBER (Chief Electrical Engineer, Keighley) detailed some experiences with petrol motor-buses, which had cost 1s. 4d. per mile, and of railless trolley vehicles, the cost of running of which he had worked out at 7d. per mile.

Mr. J. K. BRYDGES (Chief Electrical Engineer, Eastbourne) gave some particulars of the running of petrol motor-buses in Eastbourne, which ran from 90 to 100 miles per day, and cost 1d. a mile. He thought that a double-decked bus was essential which should be capable of running at least 15 miles per hour. At Eastbourne they had to carry all the coal from the railway station to the works. The Department had had a steam wagon doing the work. He had gone into the question of an electric coal wagon about 18 months ago, but the price was excessive for one thing, and the amount it could carry was limited. The steam wagon he had now cost £550, and carried 4½ tons. It was a very big proposition to have to pay £1,100, as he would have had to do, for an electric vehicle for the same work. In Eastbourne there was a good deal of heavy traffic, such as furniture removal vans and brewers' drays, and it would be a good thing for the town and for the electrical undertaking if electric vehicles be employed.

Alderman MEYER (York) supplemented Mr. Hame's remarks on the York omnibuses, and said that, with regard to speed, both trams and electric buses were being run, and both were timed to do the same amount of running per hour.

Mr. J. CHRISTIE (Chief Electrical Engineer, Brighton) had been able to persuade his committee to spend £200 to purchase piecemeal a vehicle which was depicted in the paper. That had been in use for eight or nine months, and it had been most valuable to him in running round the town in connection with his work. He ran about 20 miles a day on it. There had been a fleet of 16 electric omnibuses working in Brighton for six years, and the Electricity Department sold 800,000 units per annum for charging the Tudor batteries on these buses. At Brighton they had had an electric vehicle on trial for a week for dust collection. It was put on every road in the town, and upon some severe grades, and although it was not quite suitable for getting into the destructor, and did not work at a maximum efficiency for that reason, it had proved capable of negotiating the heaviest grades. As to charging, station engineers must assist the people who were likely to use vehicles by making preparations for charging them. He had an old boiler-house, now dismantled, at the main sub-station, which was fitted with a pit, and was capable of accommodating about twelve vehicles.

Mr. A. E. SHAW (Borough Electrical Engineer, Ilford) had gone very carefully into the matter of coal carrying, and had persuaded his Council to give an order for a four-ton electric waggon. Previous to the electric truck, the coal was carted by horses at a cost of 1s. 6d. per ton, but the price with the electric waggon was 10d. per ton. He had also an electric tower waggon which had been in use for 18 months at Ilford, had given every satisfaction, and was considerably less costly than the previous horse vehicle.

Mr. W. H. WATSON (Edison Accumulators) said that a good many remarks had been made against the speed of the electric vehicle, but this matter had not been given proper consideration. The reason why an electric vehicle was so much cheaper than other vehicles in running costs was because they did not endeavour to exceed a suitable speed. First cost did not govern

everything. The ultimate results were things to be looked to. Estimates which all makers of electric vehicles submitted were based on very careful lines. On account of the varying conditions in different towns, they were applied to give a running cost which they knew would be worked to. The users of Edison vehicles would admit that the estimates submitted for these had never been exceeded, and in many cases at least 10 per cent. saving had been shown. Notwithstanding the criticisms regarding price and speed, it was interesting to know that the railway companies were beginning to move in the purchase of electric vehicles. Another movement in the right direction was among brewers, and he had recently received orders from three or four leading breweries. He had been very closely into the matter of refuse disposal, and his company had now brought out the small type of vehicle illustrated in the paper. The capacity was approximately 2 yards, but there was another type which took 4½ yards, and the over-all cost of running it, including capital, interest, and maintenance, not including labour, was £85 per annum, assuming that the vehicle lasted 10 years, and that the mileage covered did not exceed 20 per day. He was rather inclined to think that our present method of handling house refuse was wrong, and had thought out a scheme, the idea of which was to have platform vehicles moving about and doing the actual collection. On these platforms were placed two tanks, the total capacity of which was 4½ cubic yards. Another heavier vehicle, with a very large body, was fitted with a crane, and was used to empty the contents of these tanks into the larger body. The tanks were replaced on the platform trucks, and so the work went on during the day. Having received four or five loads of this description, the big trolley went to the destructor, and thus the system of each collecting van going to the tip and wasting a lot of time was avoided.

Mr. W. WYLD (Chief Electrical Engineer, Hampstead) described arrangements by which the Hampstead Works Committee ran an electric van which they hired from the Electricity Department. A trial showed that the vehicle could do at a cost of 19s. 6d., exclusive of capital charges, what had been costing 35s. The cost of the vehicle was approximately £1,000, and he had practically come to an agreement with the Works Committee for the hire of the van and a man to drive it on the basis of a certain number of days per annum for four years, and the price charged would provide for the purchase of the machine in four years, so that the Electricity Department would have a vehicle which it could use to a certain extent during the year, whilst the hire by the other departments would repay the cost and leave the Department with the vehicle at the end of the hiring period. Meantime, the vehicle would be invaluable as an advertisement for the electric lighting department.

Mr. MEADE (Wolseley Motors, Ltd.) said that the two fields of usefulness of petrol and electric vehicles did not coincide. The petrol vehicle was the one for mileage and carrying loads for long distances. It was not one for short journeys and constant stops. Speed was everything with the petrol vehicle; speed was everything against the electric vehicle. At speeds over 12 miles an hour it would be found that depreciation and maintenance charges would be rapidly increased, because the vehicle was being used for something for which it was never intended. There were people in England to-day who with great advantage used a mixed fleet of petrol and electric vehicles. He was in agreement with municipal engineers on the question of price. It was very much too high, and would have to be reduced considerably.

Mr. AYTON replied to some of the points raised in the discussion, emphasising that the electric vehicle was a moderate speed machine for short haulage work. Although prices would come down as the demand increased, there was plenty of room for business at present figures.

A parade and demonstration of electric vehicles was held on the Embankment after the meeting, and excited much interest. We described the vehicles that were present in our last issue.

MEETING OF THE "POINT-FIVES" ASSOCIATION

THIS Association met at Tricity House, Oxford Street, at 7 p.m. as arranged. In addition to the "point-fives" themselves, there were a few other members of the I.M.E.A. and a sprinkling of visitors, the total attendance being about thirty. An excellent dinner was served, after which the Chairman for the evening, Mr. S. E. Fedden (Sheffield), opened the informal debate with a short address.

Mr. FEDDEN said that, as it was almost impossible to keep away from "the only subject that matters," a mutual interchange of experiences during the present crisis might be interesting. In Sheffield, as in other places, it was anticipated early in August that there would be a slump in business, there were rumours of reductions in staff and of half-pay to such as remained, 30 of his technical and clerical staff and about 60 other employés left to join the Forces, coal deliveries tailed

off, prices of commodities began to leap upwards alarmingly, and everything pointed to a good year being spoiled. The reaction which set in very soon, on the other hand, put a strain on the electrical undertaking nigh unto breaking-point. For the six months ended March 25th last, the units sold were more than double those of the corresponding period of the previous year, viz., 29,303,892, compared with 14,644,168. In addition to this, an additional 10,000 kw. applied for is almost ready for connection, and negotiations are in progress involving an extra 10 to 15 million units per annum. Last year's sales were 45 million units, and Mr. Fedden estimates that this year's will be at least 65 millions. The principal difficulties which have beset him have been station extensions, delivery of plant, coal, and both manual and clerical labour. Last week he had had to agree to a 7s. increase per ton for extending a contract previously at 11s. 6d. per ton.

On bringing this part of his address to a conclusion, Mr. Fedden said:—"I must, perhaps, apologise for such a digression from the usual and orthodox type of address, but in such a grave national emergency how can I bring myself to contemplate the best and most efficient way of grilling chops, or to investigate the precise temperature suitable to the correct consistency of rice pudding? There are other sterner and nobler duties to perform, and when the history of this War comes to be written, it will be found that the nation's electricity undertakings have had no small share in the ultimate triumph to which we are all looking forward with confidence, and with a determination to do all that we possibly can to bring about such a result in the shortest possible time."

Referring briefly to questions relating to electric cooking and heating, Mr. Fedden first mentioned his experience was that no hot-plates yet supplied were really hot enough for frying or omelette-making; moreover, that they took too long to get thoroughly hot, and much heat was wasted if, as happened with "hired help," the current was only turned off when the cooking was finished. [Several speakers subsequently mentioned that these difficulties were non-existent in the Belling "red-hot hot-plate."] For room heating there was want of an apparatus for fixing in a fireplace to look like a fireplace, and he suggested that 3-kw. stoves were now becoming almost too heavy for carrying from room to room. Coffee-pots for six or eight cups might have two elements, so that the slower heating could be employed when fewer cups were needed. Other criticisms he made of apparatus, to promote discussion, were that trouble was still experienced with the flex. of electric irons, and that although the electric oven was excellent for pastry and for meat, &c., it did not make good bread—at any rate, not in the quantities required by families in the north of England.

Mr. BLACKMAN (Sunderland) said that all cooking had been done electrically in his home for the last 18 months, and his large electric ovens were suitable for bread. But for this purpose they must be large. He had the flexibles of irons inspected every six weeks to avoid trouble. Cab-tyre sheathed flex. was, he found, not flexible enough; it was only a seven-strand wire. He had had good results with "terroid" flex. As to coal contracts, he had been particularly fortunate, as he had made a contract for six months last January at 1s. a ton less than last year.

Mr. ROLES (Bradford) said that on renewing his coal contract, he had been offered coal at prices 60 per cent. above the price paid last June. There was, however, a great scarcity, and he had had to pay a high price. A contract which he had just made for six months would mean an increase of expense at the rate of £12,000 a year, but it was not all loss, owing to the coal clause in the power contracts.

Mr. COOKE (Luton) agreed as to the average electric oven being too small, and the necessity of having a hot plate which would get hot quickly and cold quickly. Referring to the question of increased outputs, he mentioned that he had just placed an order for 3,000 kw. of plant for next winter.

Mr. BRITTON (Chester) said that he had been doing cooking for five years with the same oven (a Bertram Thomas) and had had only one breakdown. As this was simply an oven, he had first used self-contained utensils as well, but he found them unsatisfactory after repair, so he now used hot plates and had obtained the best result with a 3-heat hot plate.

Mr. PICKVANCE (Wrexham) said he had tested three or four different kinds of cookers in his own house during the last five or six years, and had had no failures with breakfast, and only one with dinner. Answering a question as to whether he had tried them long enough, he said that they subsequently went into consumers' houses and gave satisfaction there. He complimented Mr. Belling on the trouble he always took to meet his customers' wishes and suggestions, and the excellence of his red-hot hot-plate. Referring to coal contracts, he said that he had fixed up a contract from April 1st at the same price as last year.

Mr. G. W. DAVIS (Chairman, Ilford Electricity Committee) made a statement with regard to the Ilford case brought by the gas company. He said that it would have come before the same judge as the Long Eaton case, and it was felt that it would have to be fought to the House of Lords. With their limited revenue of under £25,000 a year, it was not worth the expense, especially as they could probably get the necessary

Parliamentary powers for all time at less cost than that of fighting the action.

Mr. HOADLEY (Maidstone) said that he could speak only as a visitor, as the charge for cooking units at Maidstone was 0'6d. and not 0'5d. In his own house, the entire cooking had been done by electricity for four years. He took weekly readings of the consumption, and during the last few weeks, when his wife had been doing the cooking instead of the cook, the units had been reduced from 50 to 30. He considered the red-hot boiling ring a great advance.

Councillor CROWTHER (Sheffield) said that he had obtained good results from electric cooking in his house, and he thought that electrical engineers should have better faith in the efficiency of their own apparatus.

Mr. BOWDEN (Poplar) said that he hoped that increase of prices would not be the general rule. The electricity works had a great opportunity at present, when the gas companies were increasing their prices, and they should continue to supply at the same price per unit as hitherto, so long as they could make both ends meet. At Poplar they had actually reduced the price for domestic lighting from 4d. to 3d., and in the case of the Point-Five tariff had reduced the fixed charge. Referring to the coal question, he said that he had bought coal in November at a better contract price than earlier in the year, but could not get it delivered. He can now buy the same coal—of the same quality and from the same pit—at 21s. instead of 10s. 6d. Within the last month he had hired forty trucks, and was now getting a quantity of coal by this means at the original contract price. Referring to the discussion with regard to hot plates, he said that in his opinion the red-hot plate was the only one which had come to stay, although he had had some trouble with it.

[Mr. Blackman suggested that this was due to its being used with alternating current, and Mr. Bowden said this was so. Apparently, from various speakers' remarks, troubles with hot plates were far more frequent with alternating current, due to connecting screws working loose—a thing that the makers might presumably easily prevent by the use of lock nuts or spring washers.]

Mr. WOODHOUSE (Yorkshire Electric Power Co.) said that there was a definite coal famine, and future prices would be greater than in the past. High coal prices were, however, really to the benefit of the electrical supply industry, as they would affect the competitive methods of lighting, heating, and power to a greater extent than the cost of electric supply.

Mr. S. T. ALLEN (Wolverhampton) said that he now gets coke dust at 3s. 4d. and mixes it with small coal, using the mixture on underfeed stokers. He proposes to put in special stokers and burn it by itself. He had been successful with electric cooking in his own house, and endorsed what had been said with regard to the Bellring red-hot hot-plate. He had put it in the kitchen for a fortnight and then taken it away for a fortnight, and put it back again, and he had found that the units always went down when it was in use. His records for faults in flex. showed that these amounted to only 2½ per cent. per annum.

Mr. RAPHAEL said that the flex. with untinned copper wires covered with a layer of cotton and then pure rubber and cotton instead of vulcanised rubber, and the whole braided circular, gave a much longer life, and he now specified this for all purposes.

Other speakers were Mr. Hame (York), Councillor Sauvage (Wrexham), Mr. Shaw (Ilford), Councillor Barge (Poplar), Mr. Williams (Jackson Electric Stove Co.), Mr. W. R. Cooper, Mr. A. S. Barnard (Chloride Co.), and Mr. Barham (Watford). Several of the Councillor speakers severely criticised the debate which had taken place at the I.M.E.A. meeting in the morning, regretting that it had chiefly been devoted to discussing the method of arriving at the fixed charge.

The meeting terminated at about 11 p.m.

The annual general meeting was held on Friday morning.

THE COUNCIL'S REPORT

(Slightly abridged.)

THE report first explained the circumstances which had affected the arrangements made for the present meeting. When war was declared, Major H. Richardson, the President, wrote that he had been called up for war service, and would be unable to attend any meetings until after the termination of his military duties. The Council appointed Mr. A. C. Cramb (the Senior Vice-President) as Acting President during Major Richardson's absence. The President at the same time expressed the view that the Convention should be postponed, but that the ordinary work of the Association should proceed as usual. Under the Articles of Association, however, it is necessary to have an annual meeting, and the Council therefore resolved that the usual Convention should not be held in 1915, but that the annual meeting should be held in London, instead of in Dundee as previously arranged. It was resolved to arrange a business meeting to occupy two days, that no social functions should be held, and that the attendance be restricted to members and

official delegates of local authorities, and to members of the Electric Vehicle and Development Committees.

Office of President, 1915-16.—Since it has become evident that there is little likelihood of Major Richardson being able to give his services to the Association throughout the ensuing year if he were re-elected to office, his views have been ascertained, and in conformity with these the Council suggest that his name should be placed on the list of Past Presidents, and they record their desire that at the first opportunity he should be nominated for another term of office as President.

Model General Conditions of Contract.—It will be remembered that upon considering the model general conditions of contract placed before the annual general meeting in June, 1913, and further considered at a subsequent extraordinary general meeting held in the following month, it was resolved that the Association of Municipal Corporations should be consulted and that until the report of a Joint Committee, composed of members of that Association and of the I.M.E.A., had been laid before the general body of members, the Council were not to communicate with the B.E.A.M.A., or any other body, on the question. The Association of Municipal Corporations was immediately approached, but that body did not move very quickly, and it was not until the day before the annual meeting of 1914 that the Council received from the Association of Municipal Corporations a proof of the document as they had amended it. Even then it had not been submitted to the governing council of that body, but only to the Legal Council, and was the outcome of a joint meeting between representatives of the Association of Municipal Corporations and of the I.M.E.A. Council held six months previously. In the meantime the Council of the B.E.A.M.A., which had not at that time been consulted by the A.M.C. regarding the proposed amendments, decided to adopt the model general conditions as issued by the Institution of Electrical Engineers for a period of one year in respect of municipal contracts in order to see how they worked. The B.E.A.M.A. asked for the views of the Council upon this proposal, and inquired if they would fall into line with it. In the circumstances no reply could be given, and the matter is left as heretofore for each Corporation to deal with the manufacturers direct. The A.M.C. has since been in negotiation with the B.E.A.M.A., but arrangements have not reached a report stage.

I.M.E.A. Bill.—The Council has decided that no further action be taken in connection with the suggestion for a Joint Private Bill, and that the Association revert to the pressing forward of a Bill promoted in the manner originally arranged. The Acting President, Mr. A. C. Cramb, had an interview with Mr. Rawlings, the President of the Electrical Contractors' Association, as a result of which the Council decided that no further concessions be made beyond those contained in the Bill as last printed. After careful consideration of the results of the I.M.E.A.'s Parliamentary propaganda in support of the Bill Messrs. A. C. Cramb, Bailie Smith, A. H. Seabrook, S. K. Fedden, and H. Faraday Proctor, were appointed as a Sub-Committee to meet the B.E.A.M.A. with a view of discussing this question with them. Particular attention is drawn to the fact that the Corporation of Glasgow has arranged terms upon which it will operate its Publicity and Sales Departments. The Electrical Contractors' Association in Scotland have agreed to these terms which are less advantageous to themselves than those to which the Electrical Contractors' Association take exception in the Bill. [See ELECTRICAL ENGINEERING, March 25, p. 128.]

Delegate's Expenses.—The Association is represented by the Acting President, Mr. A. C. Cramb, on the Committee formed by the Royal Sanitary Institute to consider the question of obtaining powers for local authorities to pay delegates' expenses to annual Conferences.

Engineering Standards Committee.—The Association is represented by Mr. A. H. Seabrook and Mr. A. C. Cramb on the Sectional Electrical Committee, and is also represented on the various electrical sub-committees. The Council has voted twenty guineas as a donation to the Engineering Standards Committee, and make a special appeal to the Committees who control municipal electrical supply undertakings to give their generous support to the Standards Committee by making an annual subscription towards the fund.

Long Eaton and Ilford Cases.—Mr. Faraday Proctor has presented a valuable report on the subject to the Council. Having carefully examined the tariffs of over one hundred of the municipal undertakings, he was of opinion that there were only a few which might be subjected to attack on the grounds of the objections alleged in the Long Eaton and Ilford cases. Some of these cases were at the time receiving consideration with a view to amendment, and in other cases the Engineers were prepared to recommend amendments if such were thought desirable.

Lamp Specifications.—The Tungsten Lamp Association invited the Council to send representatives to form a Joint Committee to discuss the outlines of the specification proposed to be put forward by the Tungsten Lamp Association. As the Council were already represented on the Sectional Committee of the Engineering Standards Committee dealing with a similar subject, they did not see that any useful purpose would be served by meeting the Tungsten Lamp Association, bearing in mind the views which the I.M.E.A. representatives held on the matter.

L.G.B. Loans.—The Council has had under consideration the action of the Local Government Board in refusing loans for extensions, &c., owing to the war. After most careful deliberation and consideration of the subject from all points of view, including that of the desirability of bringing the war to a successful conclusion at the earliest possible date, the Council felt that they could not recommend action being taken on general lines. It was thought that the case of each undertaking should be considered upon its merits.

War Office and Enlistment.—With the object of ensuring that members of the staff of electricity undertakings should not be accepted for enlistment without special permission, the War Office had been approached, pointing out the desirability of preventing the depletion of the staff below the minimum necessary for the carrying on of the works of Electricity Departments. The War Office agreed that those who were of necessity engaged on such works were doing equal service to the country as those who had enlisted. The War Office has given consideration to the question of issuing a badge or certificate of exemption, but could not see its way to fall in with the proposal.

Joint Motor Committee.—The B.E.A.M.A. invited the Council to appoint four members to form a Joint Motor Committee. Messrs. A. C. Cramb, A. H. Seabrook, S. E. Fedden, and J. W. Beauchamp were appointed to represent the I.M.E.A. The suggestion of the B.E.A.M.A. was that there should be a standard specification which should be adopted by the I.M.E.A., and that an arrangement should be made as to preferential discount to undertakings in their districts where such undertakings have the power to sell motors. The Joint Committee eventually recommended that the I.M.E.A. and B.E.A.M.A. should adopt a standard specification for direct current motors, preferably that to be issued by the Engineering Standards Committee, and until this was issued, the B.E.A.M.A. motor specification. The Council have suggested several modifications to the specification, and the matter is still under consideration.

Board of Industry.—Messrs. H. Faraday Proctor, S. E. Fedden, A. H. Seabrook, A. C. Cramb, and Bailie Smith attended on behalf of your Council a joint meeting of representatives of the B.E.A.M.A. and the British Engineers' Association to consider the question of the protection of British interests. Proposals were made for the formation of a Government Department to be entitled the Board of Industry, and it was decided to invite the I.M.E.A. to appoint a representative on the Joint Committee, one of the main objects being to secure the principle that public money should be expended only on British manufactures. Mr. A. C. Cramb (Acting President) was appointed to represent the Association upon this Committee.

Municipal Loans.—The Council has supported the recommendations made by the Institution of Electrical Engineers in regard to the periods allowed for the repayment of loans, as follows:—

- | | |
|--|--------------|
| (a) Cables substantially constructed and laid | ... 30 years |
| (b) Conduits substantially constructed | ... 60 years |
| (c) Accumulators and batteries in cases where the sanctioning authority is satisfied that adequate provision has been made for the proper maintenance of the batteries | ... 15 years |
| (d) Reinforced concrete | ... 30 years |

Institution of Electrical Engineers Benevolent Fund.—In response to the recent appeal issued on behalf of this fund the Council decided to subscribe a sum of £10 10s. from the funds of the Association.

Report of the Development Committee.

A report of the Development Committee is appended to the Council's report. The activities of this Committee have been reported in our columns from time to time (*ELECTRICAL ENGINEERING*, Jan. 7th, p. 3, March 11th, p. 104, and April 1st, p. 139), but the following additional information is of further interest. Various sub-committees, who report occasionally to the Development Committee on the progress of their work, have naturally been working under some difficulties in view of the present abnormal conditions. The Publicity Sub-Committee have, after due deliberation, insisted upon the absolute necessity of providing regular funds and the establishment of at least a small paid staff whose whole time could be devoted to the work. They have also opened communication with the Publicity Committee of the London electric supply companies, with a view, if possible, to combining the efforts of all classes of electric supply undertakings in regard to publicity, to avoid wasteful overlapping, and bring about at the earliest moment an organised campaign for the development of public electricity service. At the present time the Sub-Committee are not in a position to report progress in this direction. Communications have also been received and considered from the Society for Electrical Development. New York, the Manager of which (Mr. Wakeman) was good enough to offer assistance and, so far as possible, means of co-operation between publicity undertakings on both sides of the water, and it is hoped that in circumstances more favourable to this class of work than those at present obtaining, this idea may be developed.

The Electrical Installations Sub-Committee will proceed so

far as possible:—(a) To examine, tabulate, and describe the various methods of wiring in use, with advantages and disadvantages, with a view to bringing about any possible reductions in the cost of installation work compatible with safety. (b) To obtain the assistance and opinions of practical men in touch with this class of work, and to promote discussion on the subject. (c) To promote practical criticisms of accessories in common use, in connection with installation work, with a view to collating information which would be valuable to manufacturers and users. (d) To take an early opportunity of considering alternatives to the present design of plug contact for heating, cooking, and other purposes, particularly in regard to the possibilities of superseding the ordinary pin or concentric patterns by some more satisfactory form of plug contact.

The Secretary of the Domestic Appliances Sub-Committee has reported preliminary work done and plans for the immediate future; it is proposed to carry out various investigations with regard to hot and boiling plates, and to invite the advice and criticisms of manufacturers in connection with that subject.

The Development Committee has considered a letter from Mr. C. H. Wordingham to the Secretary of the I.E.E., dealing with the question of establishing a central testing institution or proving house. The Committee associated itself with the views expressed by Mr. Wordingham therein, but urged that the National Physical Laboratory and its existing organisation should be employed whenever possible.

Report of the Electrical Vehicle Committee.

A report from this Committee is also appended to the Council's report, and summarises the work which has been done by the Committee during the past year, most of which has been reported in *ELECTRICAL ENGINEERING* in the ordinary course. The subjects mentioned are the establishment of a standard design of charging plug; the desirability of a uniform charging tariff of 1d. per unit; the fixing of a standard charging voltage between 85 and 120, and a standard number of cells (44) for vehicles with lead batteries; and the standardisation of a sign for charging stations.

At the instance of the Society of Motor Manufacturers and Traders, the Engineering Standards Committee decided to standardise certain rims for solid rubber tyres, and the Committee decided to support the Association in this important matter by recommending that these rims, of the following sizes, should be used for all commercial electric vehicles:—670 mm., 720 mm., 741 mm., 771 mm., 850 mm., and 881 mm. The Committee have also issued recommendations with regard to the instruments to be used on electric vehicles.

Arrangements have been made with the Commercial Motor Users' Association. The Committee will have a voice in all future arrangements in regard to parades of motor vehicles, in so far as such arrangements apply to electric vehicles. The Association has also very kindly offered to allocate to the use of this Committee a section in the next edition of its "Night Shelter Handbook for Commercial Vehicles," in which the Committee can set forth information as to charging stations about the country, tariffs, &c., and the Association has also offered to include a map upon which these charging stations may be indicated.

While this report mentions the special matters dealt with by the Committee, it does not detail the many other directions in which the Committee has been active in stimulating interest in the electric vehicle, and making efforts to promote its adoption. In closing the report, the I.M.E.A. representatives on the Committee express their thanks to the co-opted members for the extremely valuable work which they have so willingly performed during the year under review, without which the progress made would have been impossible.

Discussion.

Engineering Standards Committee.—Mr. R. A. Chattock said that a considerable number of members of the Association were representatives on this Committee, and were in personal touch with the work that was being done. The Standard Specifications issued by the Committee were of great assistance to municipal electric supply engineers, and saved an enormous amount of work in the preparation of their own specifications. For this reason the Council felt that it was justified in voting a sum of twenty guineas to the funds of the Standards Committee.

Local Government Board Loans.—Mr. H. Faraday Proctor (Hon. Secretary), referring to the above, said he had a letter from Sir John Snell, who, together with Mr. Sparks, President-elect of the Institution of Electrical Engineers, Sir John Wolfe Barry, President of the Institution of Civil Engineers, and Sir Alexander Kennedy, on behalf of the Institution of Mechanical Engineers, was forming a deputation to wait upon the Treasury with reference to municipal loans. Nothing definite had been done up to the present, but the three Institutions in question were showing sympathy towards municipalities, and he only wished to assure the members of the Association that their interests were being very well looked after wherever these interests coincided with the interests for the furtherance of the war. All the members of the Association had been circulated with regard to the matter, and inquiries were made as

to what municipalities wanted loans and the purposes of the loans. He himself went very carefully through all these, and the important cases were referred to Sir John Snell, who had taken, or was taking, this matter up with the Government Departments.

Alderman Barge (Poplar) moved, and Mr. E. S. Rayner (Doncaster) seconded, the adoption of the report, which was carried unanimously.

Balance Sheet.—THE CHAIRMAN explained that, unfortunately, the Hon. Treasurer, Mr. J. S. Edgcome was not sufficiently well to be present. The balance sheet was then adopted unanimously.

The Report of the Development Committee.—Mr. S. E. Fedden, as Chairman of this Committee, introduced the report for the past year. He said that it had been decided to cut the work up into districts for different parts of the country and to co-opt persons who were not members of the Association, but who would be useful to these Sub-Committees. It had been suggested that the present time was not really opportune to carry on such publicity work, but after very carefully considering the matter, it had been decided that, whilst the Committee was not going on with its work in an energetic manner, it would keep it alive, and, if possible, get the first organisation finished, and try to do some advertising if it could be done without any heavy expense.

The Electric Vehicle Committee.—Mr. R. A. Chattock (Chairman of this Committee) called attention to the large amount of work done during the past twelve months, especially in connection with the standardising of apparatus to be used with the vehicles. He referred also to the success of the Parade on the previous day, and the quarterly issues of the Committee's Journal, and reminded the audience that contributions to the Committee's fund were acceptable.

Mr. S. J. Watson, who seconded the adoption of the Report, emphasised the splendid work which had been accomplished on behalf of the Committee by Mr. Ayton, the Hon. Secretary.

Election of Officers and Council.

The following is the result of the ballot for officers and members of Council for the year 1915-16.

President: A. C. Cramb (Croydon).

Vice-Presidents: F. M. Long (Norwich), A. H. Seabrook (St. Marylebone).

Past-Presidents: G. Wilkinson (Harrogate), R. A. Chattock (Birmingham), Major H. Richardson (Dundee).

Members of Council: J. W. Beauchamp (West Ham), A. S. Blackman (Sunderland), S. E. Fedden (Sheffield), T. Roles (Bradford), W. A. Vignoles (Grimsby), W. Wyld (Hampstead), S. E. Britton* (Chester), W. W. Lackie* (Glasgow), S. L. Pearce* (Manchester), Councillor Crowther (Sheffield), Alderman Ellaway (Birmingham), Alderman J. P. Smith (Barrow-in-Furness), Baillie W. B. Smith (Glasgow), Councillor H. R. Barge* (Poplar), Alderman Sir J. Beecham* (St. Helens).

The names marked with an asterisk are newly elected.

Place of Meeting for 1916.—It was decided that the selection of this should be left in the hands of President and Council.

Insurance Against Aircraft Damage.—Mr. H. Faraday Proctor read a letter from Mr. J. E. Edgcome, the Hon. Treasurer, asking the Association to pass a resolution urging the Government to pledge itself to bear the cost of damage to property from hostile aircraft. The Council, said Mr. Proctor, was in sympathy with Mr. Edgcome's views. The following resolution was then carried unanimously: "That this Meeting is of opinion that the Government should hold themselves financially responsible for all damage to real and personal property situated in the British Isles, directly attributable to the present war."

Coal Supplies.—Baillie Smith, who had been representing the I.E.E.A. on the National Conference, said that after the very large meeting of the gas and electrical industries which had been held at the Institution of Electrical Engineers, a Committee had been formed to approach the Government. This was done about three weeks ago, and a dozen members had an interview with the Government Committee controlling the export of coal. It was found that that Committee had the whole thing at its fingers ends, and they could trust that Committee implicitly to keep a very tight grip on the question of letting coal go out of the country to neutral countries that were rather questionable. To our Allies that Committee would see that the coal was allowed to go out. About a week ago the Committee formed by the Conference was called to the Grand Committee Room at the House of Commons, and met about 200 members of Parliament, before whom they put the case, and a very good impression was made as to the necessity for some action. On Tuesday of that week a similar meeting was held with those members of Parliament, the representatives of the gas and electrical industries being led by Sir Corbet Woodall. The result was that a committee of twelve had been formed to go into the matter, and was to meet on the previous day, and it was hoped that within a week it would report to the Government and make some recommendations as to action. The six speakers representing gas and electricity industries were unanimous on two leading points. The first was the necessity of getting miners to work at least full time. In a report pre-

sented to the Government by a Committee formed a little while ago to inquire into the conditions in the coal-mining industry, it was admitted that there was avoidable absenteeism from 4 to 12 per cent. The second point was very well spoken to on the Tuesday afternoon by Sir Arthur Markham, Bart., of Mansfield, a colliery owner himself. He told members of Parliament that a fictitious and unreasonable price was being charged by colliery owners for coal, and he recommended the Government to form some organisation that would control and fix the price of coal in each district, and at each colliery, based on the price of coal a year ago, plus the necessary increase in price, but not to allow colliery owners to charge any speculative or fictitious price over and above that. He hoped the Government would adopt that view. Certainly just now it appeared to the Committee that the Government had got a move, and that they were going to do what they had been asked to do.

The Electrical Emergency Service.—Mr. H. Faraday Proctor (Honorary Secretary) said that he had brought the matter before the Council that morning. ELECTRICAL ENGINEERING, as no doubt most people were aware, had been energetic in taking up the question of the supply of switchboard attendants. There was a considerable shortage, both in London stations and the provinces as well as, of course, of other technical assistants. Mr. Raphael (Editor of ELECTRICAL ENGINEERING) had felt for some considerable time past that men who were engaged on other work than electricity works might take occasional shifts in electricity works as switchboard attendants, and he had registered the names of many such men, and had placed several of them in stations and sub-stations in London. Mr. Raphael thought that with the support of this Association the matter might be taken up and the movement extended into the provinces. In many provincial centres no doubt that might be arranged. In centres situated in engineering districts there were many technical men with a certain amount of electrical knowledge, but in some other districts it would be very difficult to find men who would be competent to take even the somewhat light duties of switchboard attendants. The Council did not propose that this matter should be thoroughly discussed that morning, because they felt that there were so many details in the arrangements that it would take up too much time. They therefore suggested that if it met with the approval of the members, it should be with the Council to make arrangements with Mr. Raphael, and if any of the members had any difficulty in getting temporary assistants or assistants during the war, they should apply either to the Council, or direct to Mr. Raphael, upon the matter.

Electric Cranes.—At a recent meeting of the Junior Institution of Engineers, Mr. C. H. Woodfield read a Paper on cranes and brought out many of the advantages of electric cranes over those worked by steam and by hydraulic power. The former lead easily in respect of first cost, durability, economy in working and upkeep, and in ease of control. And where many cranes were employed the fact of the power supply being centralized gave them a great advantage over isolated steam cranes. For warehouses, &c., the choice was between electric and hydraulic working, and a serious disadvantage of the hydraulic crane was the fact that it cost as much to lift the minimum as the maximum load. In comparing with steam cranes, he mentioned the superior overload capacity of the electric crane, its ease of control, and the advantage that power was always available without keeping a local boiler under steam. Again, the rate of insurance was less with electric power.

Soft Soda Glass suitable for X-ray Bulbs.—The Glass Research Committee of the Institute of Chemistry find that a glass such as that made from formula No. 10, recently published by them and recommended for X-ray bulbs (see ELECTRICAL ENGINEERING, April 13th, p. 164), does not give a green phosphorescent glow if it is made from approximately pure materials. The slight glow given is blue. In view of the fact that a green phosphorescence appears to be preferred by users of X-ray tubes, it seemed desirable to determine the conditions for obtaining this effect. It has been traced to the presence of manganese, and such a glass as No. 10 will give this green glow if manganese dioxide is added to the batch mixture in the quantities frequently used to correct the colour due to iron.

The Electric Vehicle Committee.—At a meeting on June 11th Mr. A. R. Fearnley (General Manager of the Sheffield Corporation Tramways) was co-opted as the representative of the Municipal Tramways Association. It was decided to send in a request that evidence be heard by the Special Committee of the Local Government Board on Motor Traffic with regard to the effect of the use of electric vehicles. The Secretary was instructed to write to the representative electrical institutions in the Colonies suggesting the advisability of adopting the Committee's standards in regard to electric vehicles. The next meeting will be held in September.

Electric-light Switching Competition.—The following is additional to the list of successful overseas competitors published in our issue of 10th instant:—*Preliminary Certificate*—Sapper H. C. Page, R.E., 40th Coy., R.E., Wellington Barracks, Hong Kong.

COAL SUPPLIES

THE Members of the House of Commons who are interesting themselves in this matter, presided over by Lord Claud Hamilton, held a further meeting on the 15th inst. to discuss the question of the difficulties arising owing to the scarcity in supplies and the high price of coal and freights. The discussion was confined to the Members of Parliament, the deputation representing gas and electricity interests not being called upon for any further opinion.

The previous work of the deputation was referred to on p. 252 of our last issue. At the conclusion of the meeting it was proposed, and carried unanimously, that a Committee of twelve should be elected to consider the whole question and formulate recommendations to be laid before an adjourned meeting of the Members of Parliament.

The Committee is constituted as follows, viz.:

Colliery Proprietors.—Sir Arthur B. Markham, Bart., M.P., Sir Alexander Henderson, Bart., M.P., the Hon. H. D. McLaren, M.P.

Shipowners.—Sir Walter Runciman, M.P., Mr. R. D. Holt, M.P., Mr. R. P. Houston, M.P.

Workmen.—The Rt. Hon. Charles Fenwick, M.P., Mr T. Richards, M.P., Mr. B. Kenyon, M.P.

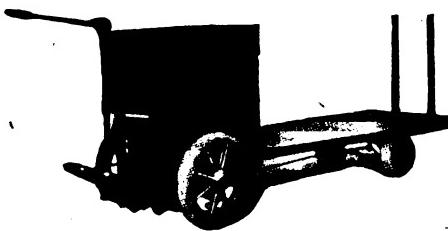

Consumers of Coal.—Mr. W. Joynson Hicks, M.P., Sir Daniel Ford Goddard, M.P., Sir Corbet Woodall.

In connection with the above, Bailie Smith, of Glasgow, made an interesting speech at the annual meeting of the I.M.E.A., reported elsewhere in this issue.

The *Times* of yesterday stated that at the final conference between Members of Parliament, coal consumers, shipowners, coal masters and miners, the following resolutions were passed:—“(1) That during the continuance of the war the maximum price of coal, for home consumption and export to our Allies, at the pit-head be fixed on the basis of the prices charged at the pit-head for substantial quantities of coal sold during the twelve months preceding the war, with an addition of 4s. 3d. per ton, or such other sum as may be prescribed, to cover the increased costs owing to the existence of the war. (2) That the rate of freight for coasting steamers employed in the coal trade be fixed on the basis of the rate charged for freight during the twelve months preceding the war, with an addition of such sum as will reasonably cover the increased cost owing to the existence of the war, and that the Government be urged to assign a further number of the interned steamers for the use of the coal trade. (3) That the Government be asked to regulate the price charged by the merchant to the consumer.” It is added that whilst the first two recommendations were passed practically unanimously, there was a considerable minority against the third. The resolutions are to be presented to the Board of Trade.

ELECTRICAL PLATFORM TRUCKS

A NUMBER of models of self-propelled trucks equipped with Edison batteries are being put on the market in this country by the Railway Track Supply Co. (80 Gracechurch Street, E.C.). These very handy little vehicles have already been taken into use by several British railways, and their advantages render them suitable for a variety of purposes in works, warehouses, and other industrial establishments where goods have to be moved about. A considerable

ELECTRICAL PLATFORM BAGGAGE TRUCK
AS USED BY G.W.R.

saving of labour as well as increase in speed is attained by their adoption—matters of great importance especially at the present time. Various patterns are made, some with flat platforms and some with drop frames, some with the mechanism above the platform and some below. The general principles of the propulsion and control are, however, the same in all of them. The motors are wound for 25 volts, except on some of the more powerful vehicles, which can

act as tractors and draw several trucks, in which case a 50-volt equipment is used.

The driver stands on a little platform in front, arranged with springs so that it is only horizontal when he is standing on it. It is made in two portions interlocked with the control and brake gear, so that as long as the driver stands on the left-hand half the main circuit is closed, but is opened automatically when he steps aft. In like manner the right-hand half keeps the brake off. Thus when the driver is not on his platform the truck is locked by the brake and cannot be started by moving the controller. As an additional safeguard the controller is arranged to take up its neutral position if released. Steering is effected by all four wheels, so that a very narrow turning circle is possible. In some cases control apparatus is provided at both ends of the truck. An enclosed motor is used, driving through a geared universally-jointed countershaft, which carries pinion gearing into an internal rack on the driving wheels. The controller is of the drum type, giving three speeds by certain groupings of the field windings. The battery is of 21 A6 cells of 225 ampere-hours capacity, and a speed of five to six miles per hour is attainable with full load of 4,000 lb. The weight of the truck complete is 1,880 lb. The details of the design are thoroughly well thought out, and the large extent to which they are used in America testifies to their utility.

ELECTRIC TRACTION NOTES

The strike upon the L.C.C. tramway system had the effect of reducing the revenue during the time it last by some £77,000.

The revenue of the Glasgow Corporation Tramways for the year to May 31st shows a decrease of about £8,000 compared with the previous twelve months.

The Hove Corporation has decided to postpone further progress with its trolley-omnibus scheme until three years after the war. This matter has been the subject of much controversy between Hove and Brighton, and at one time the Board of Trade was asked to arbitrate.

The result of the past year's working of the G.B. surface-contact system at Lincoln has been the slight increase in running costs per car-mile of from 5'91d. to 6'37d. The cost of repairs to the G.B. equipment, whilst slightly less than in the previous twelve months, is still considerably in excess of the average guarantee of £90 given by the Company, and the actual average cost of repairs to the equipment has now increased to £110 per annum. Mr. Stanley Clegg, the Tramway Manager, however, points out that evidently the £90 guarantee was on the basis that the G.B. system would be applied in many other towns, and that in consequence the cost of repair parts would be considerably less than was now actually the case when they all had to be made specially as required.

The Bill relating to the pooling of funds, &c., of the railways associated with the Underground Electric Railways Co. of London has undergone considerable change since we last referred to the matter on p. 219 of our issue for May 20th. As the result of a meeting of the promoters, opponents, and the authorities of Parliament, the promoters have agreed to strike out all powers dealing with the interchange, &c., of traffic and the establishment of a Joint Committee, thus limiting the measure to the pooling of the receipts of the companies. It has also been agreed to insert a clause preventing any powers being conferred upon the London General Omnibus Co. The L.C.C., however, is not yet satisfied, and suggests further amendments to the effect that any agreements under the Bill should be subject to the approval of the Board of Trade, the Council to have an opportunity of submitting its views; that any pooling arrangement shall be shown in the accounts, and that the Bill shall only remain in force for three years.

The report of the British Electric Traction Co. for the year to March 31st, 1915, shows a net profit of £135,057 after deducting debenture stock interest. The payment of full dividend on the 6 per cent. cumulative preference stock and 3½ per cent. on the 7 per cent. non-cumulative preference stock is recommended. The balance of £71,399 is carried forward, no sum being carried to reserve for depreciation in view of the fact that the directors now propose to proceed with the capital reorganisation scheme which was passed before the shareholders last July, but which was postponed in consequence of the war.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

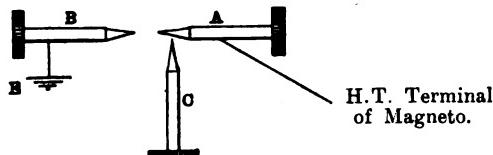

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,448.

It is the custom in testing magnetos to connect the high-tension terminal through a spark gap to earth, the gap being such as that shown on the accompanying diagram, the points

being lettered *A* and *B*. It is found, however, that when a further point, *C*, insulated from both of the others, and from earth, is introduced, as shown, the magneto sparks much more readily. What is the explanation of this?—"RADIIUM."

(Replies must be received not later than first post, Thursday, July 1st.)

ANSWERS TO No. 1,448.

A manufacturer sent a shunt motor and starter, both in perfect order and carefully inspected and tested, to a distant job. He received a telegram from his customer stating that the motor ran enormously above its rated speed. What is the most probable reason that the manufacturer would suggest for this?

The first award (10s.) is given to "E. B. P." for the following reply:—

The most probable reason for the racing of the motor is wrong connections, as shown in Fig. 2. Here the field

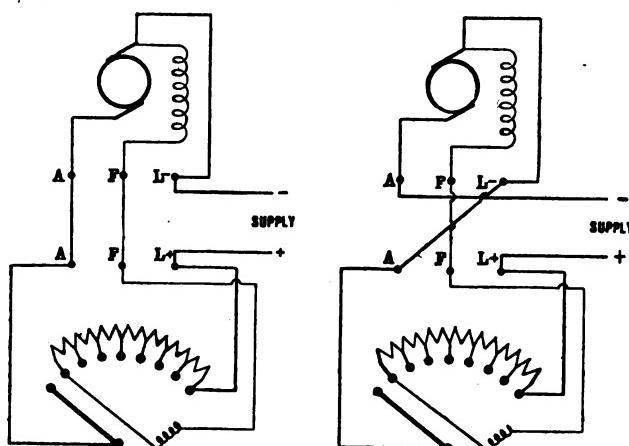

FIG. 1.

FIG. 2.

winding is connected as a shunt across the starting resistance. The effect of this is as follows. On

first switching on, practically all the voltage-drop occurs across the starting resistance; since the field is connected as a shunt across this, the P.D. between its terminals will be high and a strong field will be the result, enabling the motor to start easily. As the motor runs up its B.E.M.F. increases, and the P.D. across the starter and the field winding decreases, weakening the field. This action goes on as more and more of the starting resistance is cut out, till at full-speed position the field winding would be short-circuited and the field strength zero. The speed of the motor will therefore increase very rapidly. The correct diagram of connections is given in Fig. 1 for comparison. The terminals are lettered in the way they probably would be on the actual motor and starter, and it will be seen that the terminals affected are the "A" and "L" terminals on the motor.

The second award (5s.) is made to "E. H.," who writes as follows:—

The speed of a given motor depends upon two factors, namely, the counter E.M.F. and the exciting current. In a shunt motor on no-load the counter E.M.F. is practically the same as the terminal voltage. Now it might be that the voltage had been incorrectly specified, or that the motor was connected between the outer instead of between one outer and the mid-wire of a three-wire system. A customer, however, would probably check these points before communicating with the manufacturer. By far the most likely reason for the very high speed of the motor is that the starter has been wired to the motor terminals in the manner indicated in the figure. Any other arrangements of the connections—except the correct one—would result either in a short-circuit across the mains, or in a short-circuit of the shunt

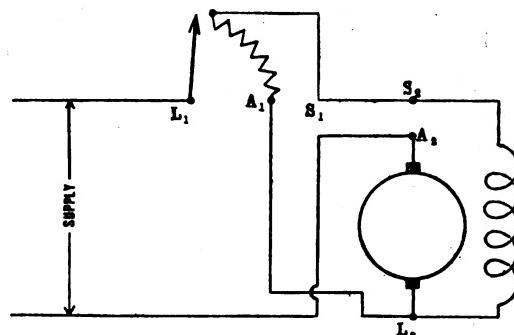

FIG. 3.

winding, so that the motor would not even start. In Fig. 3 the shunt winding is actually connected across the starting resistance. Now, when such a motor is started, by far the greater portion of the supply voltage is absorbed in the starting resistance. The current in the shunt winding is, therefore, only slightly less than its normal value, with the result that the motor starts up without any difficulty. As the speed increases and the starting resistance is cut out, the voltage across and the current in the shunt winding decrease, until, when the starter is "full on," the shunt is short-circuited. Hence the enormous speed of the motor. The connections are easily corrected by changing over the leads at *A*, and *L*, i.e., by joining *A*, to *A*, and *L*, to the line. The probable reply of the manufacturer would therefore be:—Check voltage; if correct, cross over two main leads at motor terminals.

ANSWER TO CORRESPONDENT

C. G.—(1) Small fan motors for running on A.C. circuits are frequently constructed on the same lines as D.C. motors, but usually with the field system laminated to reduce iron losses, and thus form single-phase series commutator motors. The ordinary resistance starter can quite well be used in such cases. (2) The current supplied to the electrodes of an ozone plant is at sufficiently high pressure (5,000 to 10,000 volts) to cause what is known as a silent discharge between them, and this pressure is obtained from a step-up transformer supplied with A.C. A full description of one of the ozone plants on the Central London Railway was given in ELECTRICAL ENGINEERING, Vol. VIII., page 261, May 16th, 1912. (3) We have no information as to the size of the batteries employed in the case you mention. Batteries are sometimes rated in watt-hours, but the ampere-hour rating is more usual. The lamps are most likely of the metal filament type.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 17th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

12,867/14. Heating Elements. C. O. BASTIAN. Resistances for heating purposes composed of relatively fine wire wound in a single layer on a quartz or other rod. The contiguous convolutions are sufficiently insulated from one another by a coating of oxide on the wire. (Three figures.)

13,159/14. Series Generators. COMPAGNIE DE L'INDUSTRIE ELECTRIQUE. An improved form of high-tension continuous-current series machine controlled by shifting the brushes, in which the field magnet is constructed like the stator of an induction motor, but with the slots only partly filled with copper for the purpose of reducing to a predetermined minimum value the induction in the armature teeth, and in consequence reducing the eddy current and hysteresis losses in the armature. (One figure.)

13,247/14, 13,248/14, and 6,476/15. Production and Amplification of Continuous Oscillations. MARCONI'S WIRELESS TELEGRAPH Co. and H. J. ROUND. The first of these describes an improved form of vacuum "oscillation valve" tube, which can be used either for magnifying or for producing continuous oscillations for wireless telephony or telegraphy. The tube contains a heated cathode and an anode, and has a constricted portion, to which an external metallic coating is applied, taking the place of a grid or screen within the tube. An electromagnet adjacent to the constricted portion also acts on the discharge. (One figure.) The second specification describes a scheme for using such a tube for the production of continuous oscillations, the special feature of which is the insertion of a condenser in the circuit of the coating or screen, shunted by a high resistance and potentiometer arrangement to increase the stability of the valve. (Two figures.) The last specifies the use of a cathode in the form of a tube of platinum coated with lime heated by an internal carbon filament. (One figure.)

13,362/14. Automatic Telephones. C. A. W. HULTMAN. In an automatic telephone exchange a selecting arrangement in which the subscribers' wires are arranged in bundles of any parallelogrammic cross-section, but having a plurality of the subscribers' wires along both sides of the parallelogram, each subscriber's wire being arranged in a single group, and the line selectors being arranged so as to be movable along the sides of the parallelogram to co-operate with the subscriber's wire, the line selectors being connected with number switches, which in turn can be connected with the calling subscriber, only one line selector being, however, used to perform the connection between two subscribers. (Eight figures.)

17,686/14. Joint-box Compound. W. H. WALKER. A compound for cable joint-boxes for exposed situations, which remains plastic indefinitely and protects machined iron surfaces, composed of prepared chalk 60 to 80 per cent., vaseline 10 to 20 per cent., oil risini 1 to 5 per cent., and oxide of iron paint 1 to 5 per cent.

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

DYNAMOS, MOTORS, &c.: FOX [Combined motor and generator] 7,746/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Motor control] 13,231/14; AYRES [Starting A.C. motors] 13,709/14.

Heating and Cooking: HOWARD [Liquid heater] 10,930/14;

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Erit.—One 2,000-kw. high-pressure turbo-alternator with condensing plant, switchgear, &c., and one water-tube boiler with all auxiliaries. Borough Electrical Engineer. July 5th.

HENRY WILSON & Co. and FAIRBAIRN [Electric heaters] 17,345/14; HOWARD [Water heater] 2,387/14.

Ignition: KETTERING and CHRYST [Ignition and engine-starting system] 4,762/14; VARLEY [Ignition apparatus] 5,040/14; WILLIAMS [Sparkling plugs] 14,156/14.

Incandescent Lamps: ELECTRIC UTILITY Co. and LONG [Repairing incandescent lamps] 8,683/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Manufacture of tungsten] 13,076/14 and [Shaping filaments] 14,229/14.

Storage Batteries: COUNELL and HOHNE [Battery plates] 20,671/14.

Switchgear, Fuses and Fittings: OWNBEY [Rotary switches] 3,701/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Liquid rheostats] 13,238/14; HOLT [Switches] 19,598/14; MCPHERSON and SHADWELL MFG. Co. [Lighting cinema theatres] 506/15.

Telephony and Telegraphy: SIEMENS BROS. & Co. [Circuits for semi-automatic telephones] 5,841/14; RELAY AUTOMATIC TELEPHONE Co., BRYANT and WARD [Automatic telephones] 13,173/14; CONNER and ROBINSON [Telephone systems] 13,410/14; MARKS (Delany Foreign Co.) [Telegraphy] 18,677/14.

Traction: KETTERING and CHRYST [Engine starters] 13,002 and 13,057/14; RENEAULT [Engine starters] 15,464/14.

Miscellaneous: MARSCHALL [Thermopiles] 6,102/14; BARROWS [Electric mining signals] 13,810/14; CADENCE [Electro-magnetic locking devices] 13,715/14; DIXON [Fire alarms] 17,732/14; LEA [Electric couplings] 1,600/15; MIDGELEY and VANDERVELL [Switches for motor-car horns] 3,003/15 and [Dashboard lamps] 4,276/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electrometallurgy: PERREUR LLOYD [Electrolytic production of zinc] 4,625 and 4,681/15.

Ignition: POGNON [Sparkling plugs] 6,593/15.

Miscellaneous: LANDIS & GYR A.G. [Short time switch] 6,991/15.

Applications for Suspension

10,457/06, B. HOFFELT; 2,711/10, 20,634/10, 9,941/11. SPECIAL FABRIK FÜR ALUMINIUM SPULEN & LEITUNGEN G.m.b.H. (Berlin) and 27,651/12. J. LOEWENTHAL. Aluminium Conductors. Licences have been granted on the application of G. H. Wilson, trading as the Manchester Armature Repair Co., in relation to these enemy-owned patents. All relate to the manufacture of coils of aluminium wire with the only insulation between turns consisting of a film of oxide or other aluminium salt on the surface. In the last-mentioned, a film of aluminium compounds is electrolytically deposited on a conductor of other metal.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS and TRANSFORMERS: W. GEIPEL and F. M. T. LANGE [Control of printing press motors] 5,213 and 5,214/04; B.T.-H. Co. (G.E. Co., U.S.A.) [motor-generators for searchlights] 4,379/05; B.T.-H. Co. (A.E.G.) [Motor-generators for searchlights] 15,130/08; B.T.-H. Co. and A. A. POLLOCK [Motor-generators for searchlights] 23,070/08.

Heating and Cooking: H. J. DOWSING [Electric light bath cabinets] 5,119/04.

Instruments and Meters: O. SCHULZE [Eddy current meter brakes] 13,136/08.

Telephony and Telegraphy: H. CARBONELLE [Copying telegraph] 5,187/07 and 19,516/09.

Miscellaneous: J. and G. J. SUTTON [Fire alarms] 5,087/07 and 3,204/08.

Halifax.—The Electricity Committee requires a 5,000-kw. turbo-alternator with condenser; two natural-draught cooling towers, and a water-tube boiler with superheater and mechanical stokers. Borough Electrical Engineer. July 1st.

Luton.—Extensions at an estimated cost of £27,000 have been sanctioned by the Council. The plant includes a new turbo-alternator, sub-station and converting plant, and H.T. and L.T. cables for connecting with a new sub-station in which two 500-kw. converters will be placed. (See "Tenders Received" column.)

Manchester.—Additional electric lighting plant, Baguley Sanatorium. City Architect. June 28th.

Miscellaneous

Australia.—The Sydney Corporation requires fuses and fuse-boxes. Preference will be given to British manufacturers. Further particulars at 73 Basinghall Street, E.C.

**TENDERS RECEIVED AND ACCEPTED
AND ORDERS PLACED**

Carlisle.—A contract has been entered into with the Tudor Accumulator Co. for the maintenance of the battery at the power station for ten years at £55 per annum.

Edinburgh.—A recent recommendation by the Electric Lighting Committee to accept a tender by the Stirling Boiler Co. for water-tube boilers for the new power station at Portobello at £32,286 has been confirmed by the Corporation by 18 votes to 14. There was some opposition on the ground that such large capital expenditure should not be incurred at the present time.

London.—The Postmaster-General has placed a contract with the Edison & Swan United Electric Light Co. for a six months' supply of Royal Ediswan tungsten drawn-wire lamps.

Luton.—In connection with the proposed extensions referred to in our "Tenders Invited" column, the Electricity Committee recommends the acceptance of a tender by the Brush Electrical Engineering Co. for a 3,000 to 3,700 kw. Ljungstrom turbine at £11,175.

Salford.—The Electricity Committee recommends the acceptance of a tender by the British Westinghouse Co. for a 5,000-kw. turbo-alternator. In a report by the Committee, it is stated that a similar plant ordered from Messrs. Willans & Robinson last October could not be delivered for many months owing to War Office demands upon that particular firm, hence the transfer of the order.

APPOINTMENTS AND PERSONAL NOTES

Mr. Raymond J. Mitchell has resigned his position as commercial engineer to Edison Accumulators, Ltd., to take up a position as engineer to Mr. E. Sanger Shepherd, (5, 6, and 7) Gray's Inn Passage, Holborn, whose work extends over many scientific fields, including colour photography and telegraphic transmission of photographs.

Mr. Cameron Gibson, Borough Electrical Engineer at Nuneaton, has been released by the Council for military duty.

Mr. S. J. Watson, Borough Electrical Engineer at Bury, has joined the local Munitions Committee.

Mr. R. N. Mayne, Borough Electrical Engineer at Redditch, who recently obtained a commission in the Army, has been released by the War Office at the urgent representation of the Corporation, who desire to keep Mr. Mayne at his post in view of the responsibility attaching to keeping supply going in the district.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. Geo. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £95 to £96 (last week, £96 to £97).

Agency.—A firm in Dartmouth (Nova Scotia) desires to represent British manufacturers of electrical apparatus,

fittings, and accessories. Further particulars at 73 Basinghall Street, E.C.

Bankruptcy.—Mr. Trevor Duesbury, Borough Electrical Engineer at Sutton Coldfield, has been adjudicated bankrupt.

LOCAL NOTES

Belfast: *Reconstruction of Electricity Department.*—Schemes for the reconstruction of the Electricity Department still continue to be drafted, and, judging from a discussion at a recent meeting of the Corporation, neither the Electricity Committee nor the Corporation seem to know whose duty it is to make a move next. The matter has been referred backwards and forwards between the Committee and the Corporation on several occasions, but the latest report on the matter is by Mr. T. W. Bloxam, the City Electrical Engineer. This report is now being printed.

London: *Hammersmith: The Amalgamation Scheme.*—The Council has expressed its approval of the amalgamation scheme referred to on p. 258 of our last issue.

Southampton: *"Northumberland" Clause Refused to Gas Co.*—A Committee of the House of Commons on Tuesday refused an application by the Southampton Gas Co. for the insertion of the "Northumberland" Clause in an Electric Lighting Order which has been granted by the Board of Trade to the Southampton Corporation extending the area of supply to the parish of Bitterne. The Gas Company asked that the Clause, which provides for a revision of prices every three years in the event of a loss being made upon the undertaking, should be applied not only to the extension area, but to the whole Borough of Southampton. Sir John Snell gave very effective evidence on behalf of the Corporation, and stated that in the only case in which a Gas Company had endeavoured to force the application of the Clause, he had been compelled to advise the Gas Company that the position of the borough would be worse if the Clause were enforced, as further losses would be incurred by an increase of prices. Sir John Snell also stated that in the case of Winchester a few years ago he supported the Clause on behalf of the Gas Company, but had since been compelled to change his opinion.

Torquay: *Extensions Stopped by the L.G.B.*—According to the *Western Morning News*, the L.G.B. has given instructions for the work in connection with the extension of the Torquay Corporation electricity generating station to be stopped at once. The scheme was for the expenditure of £16,000 for the supply of new machinery and the alteration of the existing buildings to hold it. Of the amount stated, £12,000 was for machinery, and the orders had been given and much of the plant completed. It is understood that the Corporation will not suffer any loss, as arrangements have been made which will be satisfactory to the contractors and the Corporation alike.

Metal Filament Lamp Patents.—In the Chancery Court on Tuesday, Mr. Justice Joyce commenced the hearing of a case in which an action is brought by Osram Lamp Works, Ltd., against Pope's Electric Lamp Co., Ltd., for alleged infringement of Patent No. 23,899/04 of Just and Hanaman, which describes a method of manufacturing "squirted" tungsten filaments. The case was opened by Mr. A. J. Walter, K.C., for the plaintiffs, and details of the process used by the defendant as revealed to the plaintiff's experts were described by Dr. Passmore in his examination by Mr. Colfax, K.C. The case was continued yesterday, and was still proceeding when we went to press. A fuller report will appear in our next issue.

Obituary.—We regret to announce that Mr. Ralph P. Hulton, who was formerly North Country Representative of Holophane, Limited, has succumbed to wounds received in the operations at the Dardanelles. Immediately upon the outbreak of war, Mr. Hulton enlisted in the Engineer Section of the Royal Naval Division.

The death is announced of Herr Rathenau, Managing Director of the Allgemeine Electricitäts Gesellschaft of Berlin, at the age of seventy-six.

The Ediswan Works.—The Society of Engineers paid a visit to the works of the Edison & Swan United Electric Light Co., Ltd., at Ponder's End, Middlesex, on Thursday of last week, where, in addition to inspecting the various processes of incandescent lamp manufacture, including the blowing of the bulbs in the recently extended glass-houses, they were shown the extensive shops devoted to switches, switchboards, instruments, and other electrical accessories.

SUMMARY

OUR advertisement pages announce a great extension in the range of British-made half-watt lamps.

AN important metal filament lamp case, in which Osram Lamp Works, Ltd. are suing Pope's Electric Lamp Co., Ltd., for alleged infringement of patent, is now being heard (p. 283).

OUR illustrated description of the electrical installation at the Regent Palace Hotel is concluded (p. 285).

SOME of the features of electrical working in mines in America are discussed in a review of an article by an American engineer (p. 286).

CONSIDERABLE trouble has been experienced in a group of mines in France, where shot-firing is carried out from a station on the surface, by the effects of lightning causing premature explosions (p. 286).

THE patents dealing with electric mining and metallurgy and published during the past month are reviewed (p. 287).

THE advantages and disadvantages of the "non-arcing" metals for use as fuses are discussed in our questions and answers columns (p. 288).

THE orders for the week of the Engineering Institutions Volunteer Training Corps are given on p. 288.

AMONG the subjects of specifications published at the Patent Office last Thursday are incandescent lamp-repairing and filaments, heaters, telephony, and A.C. motors. A Westinghouse railway signalling patent expires this week after a full life of 14 years (p. 289).

A NEW quick-break and quick-made tumbler switch is described (p. 290).

EXTENSIONS are to be carried out at Darlington (£34,950); at last the Manchester Barton power station scheme has been sanctioned; mains and transformers are required at Stalybridge (£4,000) (p. 291).

THE effect of the working agreement between Poplar and Stepney is reflected in the increased efficiency of the Poplar system last year.—A sum of about £20,000 for extensions at Salford is to be taken from the renewals fund.—The Fulham, Hammersmith, and Battersea linking-up scheme has received the sanction of the Fulham and Hammersmith Councils (p. 292).

THE OSRAM v. POPE PATENT ACTION

A S briefly announced in our last issue, a commencement was made on Tuesday of last week in the hearing of an action for infringement which is brought against Pope's Electric Lamp Co., Ltd., by the Osram Lamp Works, Ltd. The case is being heard by Mr. Justice Joyce, and the counsel for the plaintiffs are Mr. A. J. Walter, K.C., Mr. H. H. Colefax, K.C., Mr. J. Hunter Gray, and Mr. E. Lunge; and for the defendants, Mr. T. Terrell, K.C., Mr. T. E. Hughes, K.C., and Mr. E. Russell Clarke.

The patent in question is No. 23,899* of 1904 [Just & Hanaman], which will be remembered to have figured prominently in the case against the "Z" Lamp Co. in 1912 (see ELECTRICAL ENGINEERING, Vol. VIII., p. 218, April 15th, 1912). The following is a brief abstract:

It describes a process of manufacturing filaments of pure tungsten by mixing finely divided tungsten or tungsten compounds such as tungstite, tungstic acid, or tungstic sulphide with an organic binding medium such as collodion, or a solution of cellulose in chloride of zinc or cupreous ammonia oxide. The filaments squirted from the resulting paste are then carbonised (in some cases after denitration), and the carbon is then removed by passing current through the filament and raising it to a high temperature in an atmosphere of steam and hydrogen. The carbon is oxidised to form carbonic oxide, and a filament of pure tungsten is left. The filaments are then rendered uniform by submitting them to the action of current in an atmosphere of volatile tungsten compounds in the presence of a large quantity of hydrogen, whereby the tungsten deposited equalises the filaments. [The patent was amended in 1909, and was published in full in its amended form in ELECTRICAL ENGINEERING of September 9th of 1909, Vol. V., page 737.]

The plaintiffs allege infringement of this patent, and claim damages and delivery up of the articles made in its infringement. The defendants deny infringement, and allege that the invention described in this patent was not new in view of prior knowledge, and that the statements therein are ambiguous and misleading, and do not give all the particulars required for a successful result.

In opening the case for the plaintiffs, Mr. A. J. Walter, K.C., recapitulated the history and state of the art of incandescent lamp manufacture prior to the patent in question, calling attention to certain patents which would figure in the case. No. 1,535/98 of Welsbach, the validity of which had been upheld by Mr. Justice Warrington in the case against the "Z" Co., referred to the manufacture of osmium filaments containing carbonaceous materials in various ways, and decarbonising by heating in an atmosphere of steam and hydrogen. Among other patents, he referred to that of Abel (20,277/04), wherein Siemens & Halske suggested a process for making wire-drawn filaments of tungsten; but there were difficulties in working the process described, although other metals could then be made into drawn wires. There was also the German specification No. 154,262, granted to Just & Hanaman in 1903, in which tungsten was obtained from its oxychloride. The other patent (abstracted above) of Just & Hanaman covers a process in which the carbon from the binder

was burnt out, as had been done in the case of osmium, in the presence of hydrogen. This patent had also been upheld by Mr. Justice Warrington in the case already mentioned, and he contended that no other metal would work with the form of the process described, nor had anyone suggested trying tungsten in this way before this specification. Others had tried coating carbon and other filaments with tungsten, but had failed. He then read the judgment given in the "Z" case, but emphasised that he was now only dealing with the one patent. He further summarised the two processes used by the defendants. In one of these the filament, squirted from a mixture of powdered tungsten and its oxide with a carbonaceous binder, was dried and then heated in a vertical tube furnace of iridium or porcelain, gradually passing up from the cold to the hot end of the furnace to a temperature of 950° C. in a stream of hydrogen. Here it was first carbonised at the lower temperatures, and subsequently the tungsten oxide was reduced and the steam formed oxidised the carbon and burnt it out, while oxidation of the tungsten was prevented by the protective action of the hydrogen. This substantially amounted to the process described in the specification. The filaments were then heated to about 220° C. in air, which partially re-oxidised them, and again treated in a similar manner in the iridium or porcelain furnace, but this time heated to 1,850° C. to complete the action; in another process used by the defendants the heating was done in a vacuum, instead of in hydrogen.

Dr. F. W. Passmore was then examined by Mr. Colefax on matters of detail relating to the process described in the patent alleged to be infringed, and the state of the art at the time of that patent. In his opinion the facts known regarding osmium would tell nothing about the behaviour of tungsten, as there were various differences in the chemical behaviour of the two metals; there was nothing in the Welsbach patent to show how to make a squirted tungsten filament. He denied that the description of the process was in any way ambiguous or insufficient, and said that there was no need to set forth the proportions of the materials used. He had had no difficulty himself in making filaments in accordance with the description in the Just & Hanaman patent. He then described in detail the processes used by the defendants as demonstrated to him.

This description was concluded when witnesses' examination was continued on the Wednesday, and Dr. Passmore was further examined on the results of analyses of the materials and filaments showing the proportions of carbon, &c., at various stages in the process. Particular attention was drawn to the re-oxidation which occurred on the "second ovening" at 220° C. He then passed on to experiments of his own to determine what was the agent in the defendants' process by which the carbon was removed, heating the substances in question in a vacuum and analysing the gases given off. These experiments showed that the effect was due to the steam formed and the hydrogen present, just as in Just & Hanaman's process; this was shown particularly by the fact that carbon monoxide was produced. Other experiments showed that at temperature below 950° C. tungsten oxides alone were powerless to remove the carbon without water, although a vigorous action of this nature occurred above 1,000° C.

Dr. Passmore was then cross-examined by Mr. Terrell, and said that furnaces of the kind used in the defendants' process were not known at the time of the Just & Hanaman patent, although electrical heating of the filaments was. He did not admit that it was possible to make a tungsten filament by simply substituting tungsten for osmium in the process described in Welsbach's patent of '98, and would have been unable to tell without experiment whether it was possible. Some discussion also took place on a process of producing tungsten filaments by heating carbon filaments in an atmosphere of tungsten oxy-chloride when the carbon is replaced by tungsten. This process is described in an earlier German patent of Just & Hanaman, and Dr. Passmore did not quite agree that was the same process as that originally included in the Just & Hanaman English patent and afterwards disclaimed by amendment.

The cross-examination of Dr. Passmore was continued throughout the whole of Thursday's sitting. He gave it as his opinion that the carbon could not be completely eliminated by this process. Other points in which he disagreed with the defendants' view were that he thought that tungsten carbide was not formed in the defendants' process, nor could their process be considered analogous to the oxychloride process with the oxychloride replaced by oxide. He was submitted to a long cross-examination regarding the knowledge at the time of the patent proceeded on of the reduction of tungsten by hydrogen, and as to the possibilities of the process patented in America by Bottome, which produced a compound carbon and tungsten filament. Although the process depended on reduction by hydrogen and water vapour, a pure tungsten filament could not be obtained by it. Nor did the heating in the Bottome process produce a true sintering of the filament. The American patents 575,002 and 575,668 of Lodyguine were also for compound filaments. After some discussion on the details of the Just & Hanaman patent alleged to be infringed. Dr. Passmore was cross-examined on his experiments and the conditions under which they were performed, but he could not agree with the view put by Mr. Terrell that the quantity of hydrogen given off in the vacuum experiments was too low to support the plaintiffs' theory that the action was due to the effect of water vapour produced

incidentally, and not to direct action. He emphasised again that tungsten oxide did not react direct on carbon below about 1,000° C. Even when a higher temperature was reached, as in the second furnace in the defendants' process, the water action would predominate.

On Friday Dr. Passmore was further cross-examined at length regarding his experiments, but upheld the view throughout that the action was due to water vapour present. Mr. Terrell then detailed a number of experiments by the experts who would be called by the defendants. Dr. Tait's experiments were directed to proving that no free carbon existed in the filaments, as they could be dissolved in mild alkaline oxidising solvents of tungsten carbide, in which carbon was insoluble. Mr. Ballantyne had made confirmatory experiments, but witness did not regard these as conclusive, as there was a possibility that carbon might, in certain circumstances, dissolve in the reagents used. Other experiments were quoted to combat Dr. Passmore's statement that carbon did not react on carbon directly below 1,020° C., but witness again considered that they were not conclusive, as the action might have been due to water present. Counsel also cross-examined witness on further experiments of the defendants' experts to show that tungsten filaments could be made by using all the atmospheres mentioned in the Welsbach osmium patent, and that filaments could not be made satisfactorily with all the materials as stated in the Just & Hanaman specification. Another point taken up was the question of whether the Just & Hanaman specification should not be held to contemplate only heating by electric current, and Mr. Terrell suggested that this was evident from the fact that the filaments were carbonised to improve their conductivity, a view in which Dr. Passmore did not concur.

The case was then adjourned till Tuesday to give Dr. Passmore an opportunity to try further experiments.

Dr. Passmore's cross-examination was concluded on Tuesday regarding the details of various experiments. Mr. Terrell suggesting that if the witness's theory of the action was correct, the decarbonisation should be greater at the top of the filament which was longer in the hot part of the furnace. Some argument ensued on this point, but Dr. Passmore did not agree that this result would necessarily follow.

Mr. Walter then re-examined Dr. Passmore on the details of the defendant processes. Witness thought that it made any difference to the action if the filament were heated electrically, as in the specification, or externally, as by the defendants. It was impossible to make a tungsten filament according to any of the specifications cited as anticipating, and his own experiment to check those of the defendant's efforts on the making of filaments, according to the instructions of Just and Hanaman, were much more successful. Mr. Terrell afterwards put a few questions to Dr. Passmore.

The next witness was Sir James Dewar, who corroborated generally the results and inferences of Dr. Passmore during his examination of Mr. Colefax. The case was still proceeding when we went to press.

Manchester Industrial Reserve.—The Manchester Municipal School of Technology has arranged with the Munitions Committee to open a register of persons willing to devote the whole or part of their time to service in connection with munitions production. For those whose experience in engineering workshops is limited, classes, for which a small fee (five shillings for ten hours' instruction) will be charged, are to be conducted in the workshops of the School in order to provide preliminary training in order to enable suitable persons to be recommended for employment in the manufacture of munitions of war.

International Engineering Congress, San Francisco.—A booklet has been issued by the Committee of Management of the International Engineering Congress to be held at San Francisco, September 16th-25th, containing a general programme of the Congress. We are asked to state that copies can be obtained by mail from Mr. W. A. Cattell, Secretary, International Engineering Congress, 417 Foxcroft Building, San Francisco, Cal., U.S.A.

Scholarships in Heating and Ventilating Engineering.—Two heating scholarships, tenable in the Faculty of Engineering of University College, London, each of the value of £50 a year, together with £11 11s., being the amount of College fees, may be awarded in July by the Institution of Heating and Ventilating Engineering. Candidates must produce evidence that they have already pursued a course of engineering training and are familiar with the work of an engineering laboratory. The research students will be required to devote their whole time to research work in connection with heating and ventilating engineering. Full particulars can be obtained from the Secretary of University College, London, to whom applications must be made not later than Wednesday, July 7th, 1915.

The National Electric Light Association.—This year's Convention of the American National Electric Light Association has been held in connection with the Panama-Pacific Exhibition at San Francisco, under the Presidency of Mr. H. H. Scott. The meetings of the various sections were held on June 8th to 11th, and the programme included a large number of papers on technical, administrative and commercial matters.

THE ELECTRICAL INSTALLATION AT THE REGENT PALACE HOTEL

(Concluded from p. 265.)

THE circuits from the main distribution boards to the various floors are all separately metered, and these boards are fitted with G.E.C. cartridge fuses. All the switchboards, together with the local distribution boards (which are of the carrier-fuse type) and most of the accessories, were supplied by the General Electric Co., who also supplied the 180 miles of cable and the 300,000 ft. of screwed-barrel "Geekoduct" in which the wiring is carried out. All the cable used is of the 2,500-megohm grade. In the building, much accommodation was left for the wiring to save undue "cutting away," and "dummy beams" on the ceilings of the various floors have been put in for the same purpose. The draw-in boxes are watertight, and are to a special design of Messrs. J. Lyons & Co.'s electrical engineers, and the lengths of tube are screwed together with brass unions where running sockets are used in the ordinary way, thus doing away with the long thread liable to rust and short life. The distributing switch and fuse boards were also specially designed by the electrical engineers.

The usual hotel arrangement of two lamps and two 3-way switches is adopted in the bedrooms, and ordinary 10-ampere plugs and switches are put in for the electric fires. Among the fittings in the public rooms we noticed particularly some artistic but not too ornate bowls used in the large "Rotunda" lounge and elsewhere, and some neat lustre fittings in the grill-room. The large dome of the "Rotunda" lounge has a line of 30-watt lamps behind opal bull's-eyes in the risers, giving a novel but pleasing effect; and around the dome is a ring of 180 lamps, not visible from floor-level, designed to throw a considerable volume of light into the glass dome. For reasons which will be apparent to our readers, these are not now in use.

The scheme adopted for the electric bells is simpler than the usual bell-signalling system in large hotels, but should be equally effective. Each floor is complete in itself and divided into eight sections, each with a large indicator. By means of a four-point relay an indicator is also operated in the service room showing which section has been rung up. When the chambermaid goes to that particular section she is shown by the section indicator the number of the room calling. At night the bells and buzzers on the bedroom floors are switched off, and each floor is switched on to a night call indicator in the porter's office on the ground floor and another in the basement hall. All the bell-wire is 300-megohm grade and drawn in heavy-gauged screwed barrel, and no multiple cable is employed at all.

Waygood-Otis lifts are employed. There are five electric passenger lifts, each constructed to carry a load of 15 cwt.s. at a speed of 300 ft. per minute, the height of travel varying from 85 ft. to 122 ft. 3 ins.—this last travelling from the basement to the roof. The cages are fitted with safety apparatus, designed to arrest the descent of the cage in case of failure of the suspension ropes. The motors are coupled to machine-cut worm and wheel winding gear designed for smooth running.

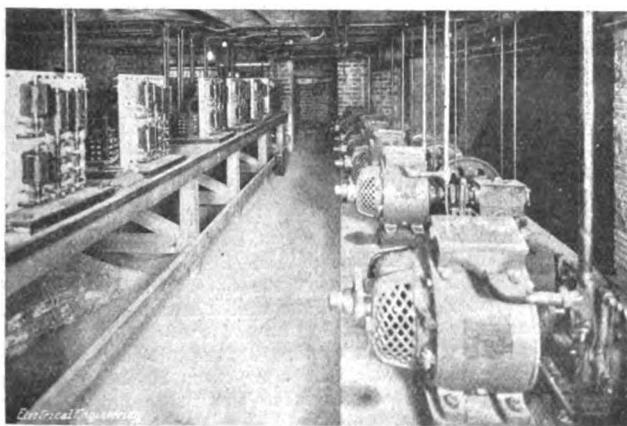

FIG. 6.—LIFT MOTORS AND CONTROL GEAR.

Each lift is controlled by a pilot switch in the cage operated by a removable handle which actuates the main controller. In each cage a flashlight annunciation signal fixture is fitted. When a passenger wishes to call a lift he pushes the button on the enclosure and this illuminates in each cage a miniature lamp representing that particular floor, and also operates a buzzer. The first cage arriving at the floor from which the signal is given will stop and pick up the passenger, and upon leaving the

floor will automatically extinguish the signal lamp in all cages. The signal is entirely automatic in its operation, and gives the operator no opportunity to extinguish it until he has reached or passed the floor from which the signal is given. The indicator also shows the direction in which the passenger wishes to travel as well as the floor on which he is standing. One call-push on each floor is arranged for two lifts, and one for the other three lifts. On the ground floor in connection with each lift is provided a mechanical indicator with arrows working on a semi-circular dial, which will show the position of each lift in the shaft. Up and down signal lights are fitted on intermediate floors, which indicate the direction in which the lift is travelling.

Fig. 6 is from a photograph of the lift motors and control gear in the basement.

There is also an electric luggage lift carrying a load of 15 cwt.s. at a speed of 300 ft. per minute, and two electric goods lifts of the same duty which travel from the basement to the ninth floor.

Fig. 7 shows the line of buffing machines for cleaning boots,

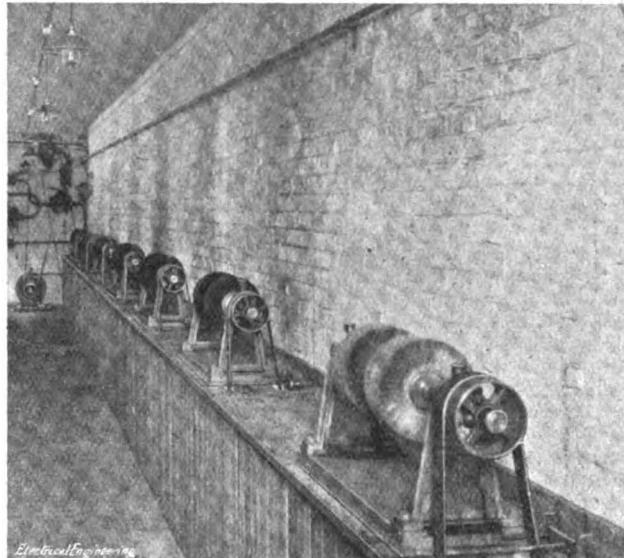

FIG. 7.—BOOT-CLEANING MACHINES.

which is driven by a small motor, and has already been mentioned among the miscellaneous applications of electric power.

There are thirty-eight "Magneta" electric clocks in various parts of the building. This system is one in which no batteries are employed. Impulses are transmitted to the dials every minute from a weight-driven master clock. This clock contains a device consisting of a bobbin with a pivoted core lying between the poles of a horse-shoe permanent magnet. This is oscillated rapidly through an angle of 45° every minute by means of mechanism connected to the clock movement, and the direction of the lines of force through the bobbin is reversed and a momentary current is sent through the dial circuits.

Time-stamps are used in various departments—twenty in all—and the clocks of these are also electrically operated from a master clock and a relay. These are independent of the electric clocks already referred to and were supplied by Rusmold's, Ltd. This system is battery-controlled on the clock side and impulses are sent by the relay every minute.

Reinforcement of Electric Light Trenches.—The question of the reinstatement of the trenches in which electric light mains are laid has been receiving considerable attention at the hands of road authorities for some time past. As the law stands at present, electric supply companies or municipal electric supply departments have to reinstate the trenches themselves and maintain them in a good condition for twelve months afterwards. In many places it has been found that this system is not satisfactory, and not infrequently arrangements are made with the road authorities to reinstate the surface of the roadway after the electric supply authority has filled in the trench. This, however, still involves certain difficulties due to subsidences in the road surface, and a strong feeling now exists that Parliamentary authority should be given to road authorities to do the whole of the filling in and reinstatement after the supply authority has merely laid the mains. Obviously, general legislation applied to all the country would be the best, but one county council, probably foreseeing difficulties in this direction for some little while to come, is endeavouring to obtain these powers for itself by means of clauses in private Acts of Parliament promoted by companies or local authorities as the opportunity arises from time to time. The matter was a subject of discussion at the annual meeting of the Institution of Municipal and County Engineers last week.

ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

ELECTRICITY IN MINING IN AMERICA

A GENERAL survey of the use of electricity in mines relating principally to American practice is given by Mr. D. B. Rushmore in the *General Electric Review*. Dealing with mining in its widest sense, the author writes that "due to the fact that a large number of mines in one locality have use for power and that in each mine the machinery is separated by considerable distances, the use of electricity as a means of transmission and application of power has very decided advantages. In fact, the age is passed when advocacy of electrification of mines has to be put forward as regards new developments. The replacement of antiquated machinery in mines which have been worked well on toward exhaustion is, however, an economic problem which does not always admit of the introduction of electrical apparatus at such a late period."

He points out that the question whether a mine should generate or purchase its power is a local condition and the size of the undertaking, but insists particularly on the possibilities electrical methods open up in the generation of power at the pit from qualities of coal unmarketable except when made up into briquettes, instancing the 80,000-kw. plant of the Lehigh Coal & Navigation Co. at Haute, Pa., as an example.

Dealing first more particularly with gold and other metal mining, he refers to the large developments of the electrically-worked shovel or excavator built on the lines of the "steam navvy" long familiar in this country. These shovels are, as a rule, equipped with three or four motors; one or two for the hoist, one for the swing and one for the boom. The two hoisting motors are located at the back of the main machinery, and longitudinally in relation to the car-frame, one on each side, and transmit their power to an intermediate hoisting shaft through bevel gears. This intermediate shaft gears direct into the hoisting drum shaft which carries the drum on which the hoisting chain is wound, this drum being provided with friction and check bands for controlling the hoisting and lowering of the dipper. The swinging motor is geared to the swinging drum through a system of spur gearing, this drum carrying two cables, one on either end, which lead forward and pass round the swinging circle connecting directly to the boom. This motor is provided with a brake, used in case of emergency. The boom motor for controlling the dipper handle is located on the boom and geared to the shipper shaft, which carries two pinions which engage with the racking of the handle. Continuous-current series motors give the best results, and the control is usually by contactors and master controllers. It is stated that a consumption of 0·241 kw.-hours is required per cubic yard under good conditions, and a very marked saving in cost is effected over steam driving. Another extensive field for electric power is in the driving of gold dredges, of which well over 100 are already in use. The bucket type is most commonly used. The machinery of a gold dredge consists of the bucket line, revolving screens, sluice tables and boxes, stacker for carrying the tailings, high and low pressure pumps. Dredge motors are mostly of the alternating-current class, the variable speed type being required for the operation of the bucket line as well as for the winch by which the dredge is kept in place or moved about. All the other motors are of the constant speed type, with the screen and stacker motors usually phase-wound. Bucket-line motors vary in size from 75 to 400 h.p., winch and stacker motors from 15 to 50 h.p., and screen and pump motors from 25 to 150 h.p. The power is transmitted to the dredges by means of armoured cable, carried on floats, and if the transmission can be economically carried out at 2,300 volts, the motors are usually wound for this voltage. For higher transmission pressures step-down transformers are, however, provided on the dredge and the pressure reduced to a motor voltage of 440.

Electric coal-cutters were first adopted in America on a commercial scale about the year 1891, and in 1912 over 15,000 were in use, cutting 47 per cent. of the total produc-

tion. The types in use do not differ in general features from those employed in this country.

The great difference between American and British underground haulage arrangements is the much more extended use of underground locomotives in the United States. These are now principally electric locomotives, although a small proportion of compressed air and petrol machines are still in use. They are usually equipped with two motors with series parallel control, and are made in sizes from 4 to 20 tons of remarkably compact design. Locomotives used for gathering are generally of a smaller capacity than those used for the main haulage. In order to obviate the use of trolley wires in the entries, these locomotives are often equipped with cable reels, containing several hundred feet of cable, the outer end of which can be connected to the trolley wire in the main entries, and through which power may be fed to the locomotive when it enters the working rooms. The cable reel is motor-operated and automatically controlled in such a manner as to keep the cable taut and rewind it when the locomotive returns. Some gathering locomotives are also in addition provided with hoist drums to be used for steep grades. There has also been a steady increased demand for the storage-battery type of locomotive for gathering work, these being built in sizes from 3 to 7 tons.

Electric winders (or, as they are more usually called in America, "electric mine hoists") were, as Mr. Rushmore points out, "first developed in Europe, and their use there had become universal before the mining interests in this country were ready to adopt them. After a campaign of education lasting over several years, their adoption in this country [America] came with unusual rapidity, and now it is only under exceptional circumstances that any other kind of hoist would be considered." Both the three-phase and continuous-current equaliser systems are employed. The author comments further on the uses of electric power in pumping and ventilation, but no distinctive features are revealed.

Finally, some statistics are given from which the following figures may be extracted to give an idea of the magnitude of the application of electrical engineering in American mining:—

| | All Mining Industries | Anthracite Coal. | Bituminous Coal. |
|--|-----------------------|------------------|------------------|
| Number of Mines, etc. | 198,688 | 429 | 6,068 |
| Total H.P. of Motors | 728,727 | 47,498 | 354,882 |
| H.P. Worked by Purchased Power | 216,108 | 1,410 | 25,294 |
| H.P. Worked by Generated Power | 14,842 | 1,152 | 9,720 |

In another part of the article it is mentioned that 510 million tons of coal were mined in America in 1914.

ACCIDENTAL SHOT-FIRING BY LIGHTNING

A N instance of trouble being experienced in the shot-firing circuits of mines due to lightning is recorded in a Paper by M. Ferez before the Société de l'Industrie Minérale, which is referred to in the *Colliery Guardian*. The mines in question, at Rochabell and Fontanes, in France, are provided with a central system of shot-firing, by which all shots are fired from a station at the pit-head after the men have been withdrawn. In some cases 30 to 50 shots at a distance of two kilometres from the firing point are exploded, and current from the 120-volt lighting circuit is employed for the purpose, the detonators in each working place being connected in series. On several occasions accidents occurred through shots going off by themselves when the control board was not even connected to the mains. In order to provide against the recurrence of such incidents, it was decided to cut the lines at the point where they passed from the shafts to the roadways, connection being made by the onsets some moments before firing took place.

They were disconnected by the workmen deputed to carry out the examination after the firing of the shots. The following measures were taken in addition. When the wire was disconnected at the pit-eye, the shaft conductors were at the same time connected with earth, a copper wire serving, before and after shot-firing, to connect each shaft conductor to the firing circuit or to earth respectively. This was replaced by a two-way switch, and by a flexible cable terminated by a brass contact, so adapted as to be connected up with a contact soldered or bolted on to the extremity of the wire extending into the mine, or to a contact with earth. A gap was thus secured of about 1 m. Certain improvements were subsequently made in the control board and insulated cables were substituted in the shafts for the bare wires on insulators previously in use, but the trouble occurred again during a storm. The management accordingly decided to establish a second gap, similar to that at the pit-eye, at a distance of about 100 m. from each of the workings. It was further decided to sectionalise each branch line by means of a gap placed at the entry of the quarter served by it, and placed as near to the workings as possible. The disconnection is made, and the wire earthed by the men carrying out the examination, and the connection is effected as nearly as possible at the end of the shift by the last workmen to go out. The effect is to diminish the capacity of the wires and the inductive influence of the atmosphere. In accordance with the mining regulations, a return wire is necessitated, and the wires will be completely insulated.

ELECTRICAL MINING AND METALLURGICAL PATENTS OF JUNE

Mining.

In Specification No. 12,885 of 1914, E. C. Theedham describes a mine-signalling apparatus, in which the handle of the transmitting key has to be partially rotated before being pushed in to make the signal. This partial rotation closes a circuit, and thus resets the indicator which has recorded the last signal, so that it is ready to record the signal about to be made. It is therefore impossible to give one signal on the top of another.

G. B. Burrows, in Specification No. 13,310/14, describes a system of electric signals for main-and-tail haulage in mines by means of current from the power or lighting mains suitably transformed. The principal feature is a series of signalling stations at junctions and terminal points equipped with means for transmitting aural signals to distant stations, and at the same time indicating in a visual manner at the sending station, and arranged so that the visual signals confirm the receipt of the aural signals. Means are also provided for indicating the sending station in the engine-room.

Electro-metallurgical.

In Specification No. 11,950 of 1914, A. M. Hanriot describes an electrolyte process for extraction by electricity of the metals silver, copper, and mercury from their ores, silver chloride, copper glance, and cinnabar respectively. These ores are placed in contact with the cathode in a conducting bath of alkaline salts, and the metal appears at the same place as it occupied in the ore.

A process for the reduction of complex sulphide ores in the electric furnace is described in Specification No. 4,937 of 1914 by F. W. Highfield. The ore, after having been roasted to remove sulphur and mixed with a reducing agent, is heated in a special form of three-phase resistance furnace in a reducing atmosphere to a temperature (about 950° C.) at which zinc is volatilised but lead is not, so that the lead can be run off in a liquid condition and the remaining matter heated electrically to the heat of formation of silicious slags (about 1,300° C.). The copper and iron sulphides can be further decomposed in the same furnace by the action of a continuous current. The furnace employed is described in more detail in Specification No. 2,728 of 1915 by the same inventor. It has a cast-iron body lined with silica and with an inner lining of magnesite or other second-class conductor. There are three water-cooled electrodes 120° apart at the sides for the main three-phase heating current, and separate electrodes for the continuous-current for the further electrolytic reduction. One of these, of a carbonaceous character, is in the centre of the bottom of the bath, and the other, also water-cooled, is suspended from the roof.

FARADAY HOUSE

(ESTABLISHED 1889)

The Electrical Standardizing, Testing & Training Institution, Ltd.
62-70, Southampton Row, London, W.C.

TESTING LABORATORIES

FARADAY HOUSE—Undertakes TESTS of every kind of ELECTRICAL MACHINERY, APPARATUS, and MATERIAL.
LOANS CALIBRATED INSTRUMENTS.
Gives facilities for Private Tests in separate Test Rooms.

Scale of Fees on application.

FARADAY HOUSE
SOUTHAMPTON ROW, LONDON, W.C.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,449.

At present, owing to the war, it is difficult to obtain supplies of small dry batteries used for pocket flash lamps. Is there any good and simple way of refilling the used cells?—"Lux."

(Replies must be received not later than first post, Thursday, July 8th.)

ANSWERS TO No. 1,447.

Why have the so-called "non-arcing metals" not been generally adopted for fuse-wire?

The first award (10s.) is given to "C. H. W." for the following reply:—

The non-arcing metals—certain brasses, zinc, cadmium, bismuth, mercury, &c.—are so called on account of the fact that an alternating current arc cannot easily be maintained across a short gap between electrodes made of such metals. The Wurtz multigap lightning arrester consists of a number of short air gaps in series between non-arcing metal electrodes: The number of short gaps making a total gap sufficient to hold the line voltage. Wurtz found that if the gaps are long, say half-inch, the short circuit may be maintained, that is, the arc will not necessarily be suppressed. The necessity for the gap to be kept very short, and for the electrodes to be massive in order to get rid of heat, makes it difficult to employ fuse-wire of non-arcing metal. For if such a fuse-wire of ordinary length melted at a point along its length, the non-arcing electrodes formed of the remainder would be of small mass, and the gap would be too large. It might conceivably be possible to employ an exceedingly short non-arcing fuse wire between fairly massive non-arcing electrodes, but there still remains the difficulty that it is only alternating arcs which are suppressed. For direct current these metals would not be effective, as shown by the following considerations. While the vapours of mercury, zinc, &c., are good conductors when the current is passing through them, they become practically insulators when the current ceases at the end of the half wave. Hence it is that the arc cannot be restarted by the next half wave of voltage unless there is impressed a very high initial voltage to break the gap down. Thus for ordinary circuit voltages the arc ceases at the end of the first half wave of current. With carbon electrodes, owing to the high boiling point, the vapour being at a high temperature remains fairly conducting after the current has ceased, owing to the current wave going to zero value. Thus the arc can be restarted by the next half wave of voltage without any necessity for a high "breaking down" pressure. It will be seen from this short explanation that the non-arcing properties of mercury, zinc, &c., are confined to alternating-current circuits.

The second award (5s.) is made to "L. R.," whose reply is given in slightly abbreviated form below:—

Although the non-arcing property of certain metals is valuable from the fuse point of view, and although these metals possess certain other useful properties common with the arcing metals, yet on the whole the disadvantages outweigh the advantages. With some non-arcing metals, viz., with zinc and cadmium, mechanical weakness is found, and they cannot be obtained satisfactorily in the form of wire. With aluminium,

although these difficulties are overcome, special spring arrangements may have to be used to make a satisfactory fuse. The non-arcing metals generally speaking are oxidising metals, and are capable of forming oxide sheaths strong enough to hold up the metal after fusion, so that in some cases a sheath is formed which contains molten metal, and this permits the passage of current after the fuse has theoretically blown. Other points have also to be noted, as, for instance, the surface tension of the molten metal as influencing the globules formed, and whether the globules burn in air or not quite apart from the non-arcing properties of the metal.

The boiling points of lead, tin and zinc are approximately 1,000° C., and it is certain that many of the globules of these metals scattered on disruption approximate to this temperature. In general it may be taken that the mass of metal in a fuse should be as small as possible. The kind of difference obtained with various metals from the no-arcing point is as follows, taking a fusing current of about 40 amperes:—Copper wire, minimum no-arc length, 4½ in., and zinc strip, 3 in. This varies somewhat according to the voltage, short-circuit current, and the inductance of the circuit, but under the same conditions in open type fuses the minimum no-arc length for zinc is always decidedly less than copper. Zinc blows fairly cleanly, the molten metal is not scattered far, but occasionally globules show a tendency to continue to burn in air where they fall. On the whole, therefore, it is a good material from a short-circuit point of view. With enclosed fuses on the other hand the minimum no-arc length is found to be somewhat greater for zinc than for copper, viz., for the 40-ampere fuse, zinc strip, 2 in., copper 1·3 in. This is due to the greater mass of metal involved for a fuse of given capacity, and to the molten metal being confined by the filling. Possibly, also to the metal vapour not being so quickly oxidised as when the fuse is in air. Zinc, again, gives rise to a high inductive voltage rise at the breaking of the circuit, and the arc formed (even with non-arcing metals there is always really some instantaneous arc formation), is unstable. Further, the inductive pressure rise seems to be irregular, and the break is sluggish. On the whole the same applies to aluminium, the inductive voltage curve being usually very peaked, although sometimes the total rise is not very high, and the arc persists for a longer period. Cadmium is very similar to zinc, the maximum voltage rise being rather greater, and it takes a considerable time to die away. It is better than copper from the point of view of the duration of the arc. All the no-arcing metals are comparatively sluggish, and this is accentuated with an enclosed fuse, the greatest difference in time element being, say, between an open fuse of copper and an enclosed fuse of a sluggish metal, such as tin or zinc. Thus the non-arcing metals are not sensitive as fuses. Silver and copper yield the quick-acting fuses, while lead, tin and zinc the slow-acting, and of these last three, zinc is the slowest, but as it has the least mass the amount of metal scattered when the fuse is blown is less than in the case of lead and tin. Tin is the most economical metal to use, then come silver, aluminium (with spring attachment), copper, and aluminium without spring, in the order named.

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING JULY 10TH, 1915,
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

On Mondays, Wednesdays, and Fridays, drills at 6.30 and 7.30 p.m. Technical instruction will be given by instructors of the London Electrical Engineers for one hour, and squad and platoon instruction for one hour on Monday and Wednesday. On Friday, company and squad drill. *Orderly Sergeant*, H. N. Fullerton. *Recruit Orderlies*, Squad 3:—C. F. McInnes, Squad 4:—W. H. G. Saunt.

E. G. FLEMING.

(*Company Commander and Acting Adjutant.*)
The Temporary Headquarters are at Marconi House, Strand, W.C. (Tel.: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W.

Employment of Disabled Sailors and Soldiers.—The Council of the Institution of Electrical Engineers desire to call attention to the demand for employment from disabled sailors and soldiers. The number at present requiring employment is not very large, but it may increase considerably during the next few months. The Committee, which deals with the question of the employment of these men, is the Association for the Employment of Ex-Soldiers, 119 Victoria Street, Westminster, London, S.W., to whom all applications for further information and lists of the local branches of the Association should be addressed. Many of the men could, no doubt, after some training, do useful work as switchboard attendants. Attention is also drawn to the Report of the Local Government Board Committee upon the provision of employment for sailors and soldiers disabled in the war, copies of which can be obtained from any bookseller, at the price of 1½d. each.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 24th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

8,683/14. Repairing Lamps. ELECTRICAL UTILITY Co. and R. W. LONG. A method of repairing a broken incandescent lamp which consists in removing the hub from the brass cap, cutting through the hub transversely at about the middle part of its length, and sealing to the cut surface of the flanged portion of the hub a counterpart of the hub that has been cut off.

10,930/14. Immersion Heaters. A. HOWARD. An improved form of immersion heater of the class in which the liquid is heated by alternating current actually passing through it between concentric tubular electrodes. (Two figures.)

13,076/14. Tungsten Filaments. B.T.-H. Co. (*G.E. Co., U.S.A.*). A method of rendering drawn tungsten wire capable of taking a permanent set without heating, which consists in heating the wire after drawing in an oxidising atmosphere, and then heating the oxidised wire in an evacuated chamber or in nitrogen or hydrogen with or without water vapour.

13,410/14. Telephony. M. S. CONNER and R. E. ROBINSON. In connection with branch exchange switchboards of the battery signalling type, junction circuits between the main and the private branch exchange and relays associated with these circuits arranged so that when a main exchange subscriber is connected through one of the junction lines to a private branch subscriber and the latter hangs up his receiver, clearing signals are simultaneously operated, one at the main exchange and one at the branch exchange, the signal at the branch exchange being located in the junction line circuit. (Five figures.)

13,709/14. Starting A.C. Motors. W. E. M. AYRES. Starting apparatus for slip-ring induction motors, comprising mesh connected resistances for the rotor phase windings and a controller arranged to short-circuit portions of the resistance in each of two phases alternately, no portion of the resistance in the third phase being short-circuited. (Five figures.)

14,229/14. Shaping Metal Filaments. B.T.-H. Co. (*G.E. Co., U.S.A.*). A method of giving a zigzag shape to continuous filaments consisting in winding a number of turns of the wire, each turn of figure 8 form on a pair of conducting supports, and heating the wire by passing current through it from one support to the other. In the case of tungsten the temperature is about 2,000° C. (Three figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Arc Lamps: MOUL (*Kürtting & Mathiesen A.G.*) [Reflector for arc lamps] 5,345/14.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: WITTRIN [Means of attaching insulators] 5,240/14; BEAVER and CLAREMONT [High voltage cables] 20,549/14.

DYNAMOS, MOTORS AND TRANSFORMERS: BERRY [Transformers] 14,030/14; SCOTT [Armatures] 14,043/14; A. E. G. [Insulation of armature coils] 14,044/14; JEFFCOTT [DYNAMOS] 14,415/14.

Incandescent Lamps: ELECTRIC UTILITY Co. and LONG [Incandescent lamps] 8,684/14.

Instruments and Meters: SIEMENS, SCHUCKERTWERKE GES. [*Meters*] 6,341/14.

Switchgear, Fuses and Fittings: A. E. G. [Feeder switching system] 5,467/14; ADAMS [Lamp holders] 12,059/14; DUNSIFFE [Switches] 14,733/14; CUSTER [Controlling devices] 14,974/14; RAILING and KRAUSE [Fuses] 18,276/14.

Telephony and Telegraphy: SIEMENS & HALSKE A.-G. [Semi-automatic telephones] 19,518/13; BETULANDER and PALMGREN [Automatic telephones] 17,415/14; IMRAY (*Siemens & Halske A.-G.*) [Selectors] 23,930/14; SIEMENS BROS. & CO. (*Siemens & Halske A.-G.*) [Automatic telephones] 24,227/14.

TRACTION: JANSSEN [Current collectors] 6,182/14; SIEMENS BROS. & CO. and FERREIRA [Signalling] 6,520/14; COLAS [Track contact rails] 14,006/14; O'DONNELL and GLENN [Signalling] 14,024/14.

Miscellaneous: MÖLLER [Electrical dust precipitation] 18,357 and 19,732/13; WILLIAMS [Burglar alarms] 11,097/14; WOOLSCROFT and H. T. BOOTHROYD, LTD. [Connectors] 11,156/14; SIEMENS, SCHUCKERTWERKE GES. [Cooling of electric drilling machines] 14,022/14; HILL (*Apparate-Bauanstalt Fischer Ges.*) 17,797/14; CADENEL [Electric locking devices] 8,060/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: A. E. G. [Arc lamp with tungsten electrodes] 8,272/15.

DYNAMOS, MOTORS, &c.: SIEMENS, SCHUCKERTWERKE GES [Slot-closing devices] 7,923/15; BRESLAUER [Unipolar driving system] 8,334/15.

Telephony: TURRI [Telephone instruments] 7,963/15; GES FÜR DRAHTLOSE TELEGRAPHIE [Wireless receivers] 7,358/15.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:-

13,468/01. Railway Signalling. WESTINGHOUSE BRAKE Co. and E. DE M. MALAN. A system of electrically interlocking railway signal levers.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS, and TRANSFORMERS: MAVOR and COULSON and H. A. MAVOR [Induction motors with primary and secondary both capable of rotation] 5,926/04; R. D. MERSHON [Induction motor control] 5,564, 5,564A, and 5,565/07.

Incandescent Lamps: B.T.-H. Co. (*G.E. Co., U.S.A.*) [Filament cutting-off machines] 5,576/07.

Instruments and Meters: V. A. ARCIOMI [*Meters*] 5,891/02.

Switchgear, Fuses, and Fittings: SIEMENS BROTHERS & CO. (*Siemens & Halske*) [Cartridge fuses] 5,802/02; A. P., C. G., and P. A. LUNDBERG [Tumbler switches] 5,826/07.

Telephony and Telegraphy: C. WIRTH [Wireless selector] 5,811/09.

Miscellaneous: H. LELARGE [Separator depending on conductivity] 5,799/04; C. O. BÄSTIAN [Mercury vapour lamps] 5,892/04; A. ZÜND [Electric aural massage] 4,525/07; W. D. WHYTE [Magnetic compass] 5,068/08; H. GRAY [Cables] 5,199/08.

Diesel Engine Users' Association.—At the June meeting of this Association the question of a suitable allowance for depreciation of Diesel engine plant in connection with income-tax assessment was considered. It was generally felt that the present practice of allowing only 5 per cent. for depreciation, and that only on the diminishing capital value, was quite insufficient for the purpose. A somewhat larger percentage had recently been offered in the case of the Diesel engine plant of an electrical undertaking, but the increase offered was only small, and it was thought that if Diesel engine users generally would take some action in the matter, and protest against the inadequacy of the present allowance, the income-tax authorities might be persuaded that a more liberal treatment in this respect was only just and reasonable. After some discussion the question was adjourned for further consideration.

The next meeting of the Association is to be held on Wednesday, July 21st, when the questions of lubrication and of cracked pistons are to be further discussed. Information and particulars concerning the Association can be obtained from the Acting Hon. Secretary, Mr. Percy Still, 19 Cadogan Gardens, London, S.W.

Relationship between Production and Sales Departments.—On the 17th inst., at the last meeting of the Sales Managers' Association before the summer adjournment, Mr. H. Williams read a Paper on this subject. He emphasised the necessity for co-operation between the outdoor selling staff and the office staff, and suggested that greater financial accommodation towards customers in the future than has been the case in the past on the part of British traders will be a dominating factor in our trade. One of the reasons of the success of Germans in trade had been the extraordinary terms of credit they were prepared to give. Many of the suggestions put forward were mere elementary truths, but it cannot be disguised that their existence in many cases seems unknown, judging by the methods that are sometimes employed. A number of speakers took part in the subsequent discussion.

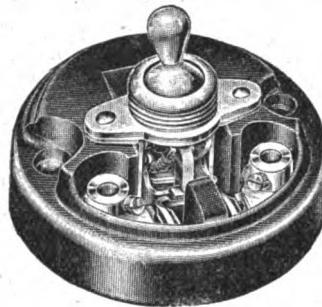

Obituary: Killed in Action.—We regret to hear that three members of the staff of the County of London Electric Supply Co. have been killed in action. Mr. A. P. Featherstonhaugh, who had been with the company 14½ years, was a sergeant in the London Rifle Brigade, Mr. G. Boast was serving in the 23rd County of London Regiment, and Mr. P. G. M. Brown was in the London Rifle Brigade.

We regret to record the death, at the age of 83, of Mr. C. E. Spagnoletti, a Past-President of the Institution of Electrical Engineers, who was one of the pioneers in the electrical industry and the founder of the well-known engineering firm bearing his name, which was recently converted into the Park Royal Engineering Works, Ltd.

A QUICK-BREAK AND QUICK-MAKE SWITCH

WE illustrate here a new pattern of quick make and break tumbler switch that has just been put on the market by J. H. Tucker & Co. (King's Road, Hay Mills, Birmingham) in response to a demand which has existed for some time from consulting engineers. The new switch is uniform in size and external appearance with our standard flat type switches. The diameter of the base is 2½ in., whilst the over-all projection is only 1½ in.

The movement is of simple, sound construction, and a positive action is obtained in the initial opening and closing of the switch. The contacts are of special design to obtain great flexibility and reliability of contact. Micanite only is used throughout for insulation, whilst the bases are of highly

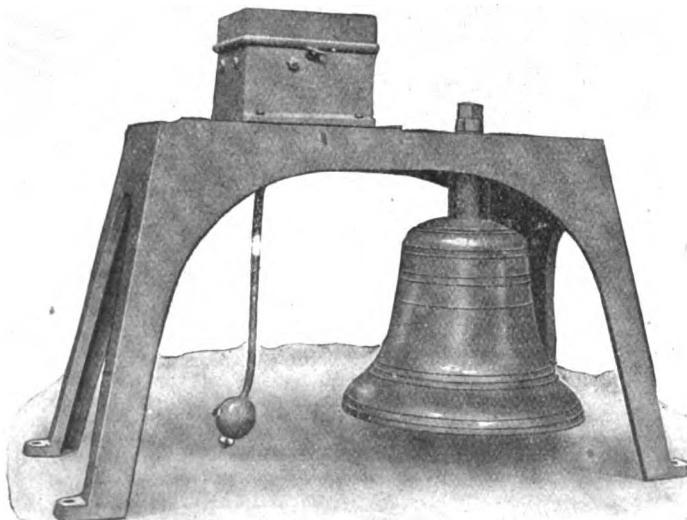

QUICK MAKE AND BREAK
TUMBLER SWITCH.

vitrified porcelain. The switch-knob is in the same relative position when the switch is "on" or "off" as the knob of the ordinary tumbler switch, and there is, therefore, no confusion to be expected in this respect. It is the firm's invariable custom before placing any new apparatus on the market to submit same to very stringent tests in their works. We are informed that the movement of this particular switch has been mechanically operated on test for over 2,000,000 times without breaking down. Switches with quick "make" and "break" movement are now ready in the ordinary "one-way" form, and also in the "two-way," with china or brass covers, in either plain or fancy forms and in many different styles of finish.

ELECTRIC BELLS AND ACCESSORIES

A NEW edition has just made its appearance of the catalogue of electric bells and accessories of the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), which is a very complete production, containing prices and particulars of a very large number of types of bells of the ordinary trembler, single-stroke, and relay patterns, as well

LARGE PATTERN OF ELECTRIC TOLLING BELL.

as large tolling bells for works, fire alarms, &c., up to the 4-cwt. bell illustrated here. The special designs include watertight and gastight bells, tramcar bells, &c. The variety of indicators is as great as that of the bells, and a still greater number of designs of pushes are listed. Among special apparatus may be mentioned a wind-direction indica-

tor, transformer for working bells, &c., from A.C. mains, and relays for special purposes. The list also contains burglar-alarm apparatus, lightning conductors, mine exploders, and other apparatus, and a full range of wet and dry batteries forms a prominent feature.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Darlington.—A L.G.B. inquiry was held last week concerning a loan of £34,950 for extensions to the electricity undertaking. In support of the application, a representative of the North Eastern Railway Co. gave evidence that the Company's North Road shops, which are steam-driven, are to be converted to electric drive; that the shops are employed on Government work; and that this would probably be increased very shortly. The Inspector elicited the fact that of the amount asked for, £11,000 are required for mains and services during the next three years, but the Town Clerk assured the Inspector that there was no intention to spend a penny on mains that could be avoided.

London: Stepney.—The Finance Committee of the L.C.C. recommends sanction to a loan of £24,000 for additional boiler and engine house plant.

Manchester.—Sanction has been received to the borrowing of £432,470 for carrying out the first section of the new Barton power station.

Mansfield.—Sanction has been given to a loan of £2,000 for plant in connection with supply to the military camp.

Stalybridge.—The Joint Board has received sanction to borrow £4,000 for mains and transformers.

Wiring

Edinburgh.—Electric lighting of public washhouse, M'Leod Street. City Electrical Engineer, Dewar Place.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Aldershot.—Additional block at Isolation Hospital. Borough Surveyor.

Bury.—Sanatorium. Clerk, Joint Hospital Board.

Castleton.—Extensions to works, Ormerod & Sons.

Ely.—Isolation Hospital. Architect, S. J. Wearing, 15 Upper King Street, Norwich, or City Surveyor, Ely.

Hanwell.—Isolation hospital (£4,000).

Harrogate.—New art and music rooms at Ashville College. Architect, James Hartley, Skipton.

London.—Enlargement of Royal Free Hospital (£30,000).

Malvern.—New school.

Manchester.—Reconstruction of Union Mill, Audenshaw, after fire. Proprietors, J. & W. Hamer.

Paignton.—Extensions to Isolation Hospital (£2,500).

Rushden.—New school.

Scarborough.—Business premises, corner of Queen and Market Streets. Architect, J. C. Petch, Bar Chambers.

Sunderland.—Considerable extensions at Borough Sanatorium, Hylton Road. Borough Surveyor.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Oldham.—The tender of the Corporation Electricity Department for lighting the Higinshaw School has been accepted at £200. Our local correspondent states that a good deal of annoyance has been caused among electrical contractors in Oldham by this decision of the Education Committee, and particularly with the remark of one local councillor, that he did not know of any local contractor who could do the work. It is probable that the matter will be raised at the next meeting of the Corporation, as it is regarded not so much as a matter of municipal trading, but as an instance of one municipal department helping or "obliging" another.

Salford.—A contract for a 1,000-kw. rotary converter and transformer at £2,820 has been placed with the British Westinghouse Co. W. T. Glover & Co. are to supply H.T. cable to the approximate value of £1,457.

APPOINTMENTS AND PERSONAL NOTES

The City of Dundee Fortress Engineers (1st Company), under the command of Captain H. Richardson, City Electrical Engineer to the city, got an enthusiastic send-off on Tuesday afternoon when they left for France. Headed by the Royal Scots Band, they marched from headquarters to the station, where the departure was witnessed by a large crowd, including the Headquarters Staff, Captain Richardson's brother officials of the city, the Lord Provost and Town Councillors, and the chief members of the staff of the Electricity Works.

Mr. W. J. Cridge, who joined the Queen's Westminster Rifles in November last, has been gazetted as Second Lieutenant in the Sherwood Foresters.

Mr. R. H. Cridge has received an appointment in the control gear section of the British Westinghouse Electric & Manufacturing Co., Ltd. (Trafford Park, Manchester).

With reference to our Note last week to the effect that Mr. Cameron Gibson, Borough Electrical Engineer at Nuneaton, had joined the Forces, it was reported at the last meeting of the Council that Mr. Gibson had been appointed Lieut.-Commander, R.N.V.R., and it was decided to allow him £200 per annum during his absence, this allowance to be modified in the event of promotion to higher rank.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £94 10s. to £95 10s. (last week, £95 to £96).

Advance in Prices.—The General Electric Co. give notice of the following advances on their list prices:—Fittings, 20 per cent.; fittings accessories, 50 per cent.; heating and cooking apparatus, 20 per cent.; and lanterns, 20 per cent.

The Bastian Meter Co., Ltd., have been compelled to advance their prices by 20 per cent.

LOCAL NOTES

Bradford: Satisfactory Electricity Profits.—The net profit on the electricity undertaking last year was £18,955, an increase of £4,050 over the preceding year.

Dublin: Increase in Electricity Charges.—In dealing with a proposal to increase the electricity charges last week, the Chairman of the Electricity Committee said the point which had to be considered was whether the consumers should be asked to pay extra or whether a deficit of £21,000 should go on to rates. Having considered the matter very carefully, the Committee proposed to increase the lighting charge by 1d. per unit and the power charge by 1d. per unit. There was a long discussion, and eventually the recommendation was carried by 34 votes to 11.

Glasgow: Smoke Abatement Exhibition.—A Smoke Abatement Exhibition is to be held in the Exhibition Hall, New City Road, from Sept. 23rd to Oct. 16th, under the patronage of the Corporation. The preliminary classification of exhibits includes, of course, electric lighting, heating, cooking, and power. Mr. James M. Freer, 38 Bath Street, is Manager.

London: Hampstead: Decreased Electricity Receipts.—

The net income of the Electricity Department last year was £69,724, or £2,163 less than the previous year. The net profit was £2,766, compared with £6,258 in the previous twelve months. Mr. W. Wyld, Chief Electrical Engineer and Manager, reports that the number of consumers being charged upon the maximum-demand system continues to decline, the flat rate being more popular. A gratifying increase in the supply of energy for power, heating, and cooking is taking place. The policy of hiring out apparatus continues to meet with success, the number of heaters having increased from 101 to 200 in the twelve months, cookers from 24 to 55, motors from 5 to 18, and miscellaneous apparatus, such as fans, &c., from 9 to 28.

Fulham: The Linking-up Scheme.—The linking-up scheme between Fulham, Hammersmith, and Battersea, referred to on p. 258 of our issue of June 17th, has received the sanction of the Council.

Poplar: Large Electricity Profits.—In the course of a debate at the I.M.E.A. meeting this year on the "Point-Five" tariff, Mr. H. W. Bowden, the Borough Electrical Engineer, mentioned the very satisfactory figures of profit which his undertaking showed for the past year. The accounts which have just come to hand bear this out. The net profit after providing for capital charges and a number of miscellaneous items amounting to £1,435 was £14,749, compared with £8,010 in the previous twelve months. Adding to this the unappropriated balance from last year's accounts, there is a net available surplus of £19,966, and of this £9,346 are recommended for allocation to a large number of details, many of which are of a capital nature. It is proposed to keep in hand a working balance of 10 per cent. of the total income and leaving a sum of £5,785. Of this Mr. Bowden recommends that a part should be retained in hand for at least six months in view of the war. It is interesting to note in the accounts that the reciprocal supply with Stepney is the dominating factor in the improvement of the efficiency of the system from 80·98 to 81·37 per cent. by saving works units when shut down. This agreement will obviate the necessity for further extensions until the maximum demand upon the Poplar undertaking has reached 10,000 kw., and allows for an output of 25 million units per annum, which will probably answer all demands until the winter of 1917.

Stoke Newington: New Loan.—A loan of £4,000 has been sanctioned by the L.C.C. for mains and meters.

Northampton: Objections to New Power Station.—The proposal recently mentioned in our columns of the Northampton Electric Light & Power Co. to erect a new power station has been objected to by a number of people, including the Corporation, on various grounds. It is proposed to erect the new power station just outside the Borough boundary, and there were the usual objections from residents on aesthetic grounds. These, however, judging from the remarks of Mr. A. P. Trotter, who held an inquiry into the matter last week, are not likely to have much weight. The chief objection, however, comes from the Corporation on the ground that, if erected, the new power station, which would constitute the Company's chief works, would be outside the Borough and affect the rateable value of the existing property of the Company inside the Borough. Mr. Trotter did not think that the question of the rateable value could be gone into, but only the matter of nuisance likely to arise from the works. All the objectors having been heard, the inquiry was closed.

Salford: Meeting Cost of Extensions.—The Finance Committee, reporting upon the Electricity Committee's recommendation to spend £19,225 for new plant, as mentioned on p. 262 of our issue for June 17th, recommends that the amount be taken from the depreciation and renewals fund, and not borrowed in the ordinary way. At the last meeting of the Corporation this proposition was discussed in private, and eventually was passed by 28 votes to 9.

Swansea: Heaters and Cookers on Loan.—In reporting a profit of £1,786 upon the electricity undertaking last year compared with £3,313 in the previous year, the Borough Electrical Engineer recommends the loaning to consumers of electric heaters and cookers, and further points out the possibilities for development in the use of electric vehicles.

Ediswan v. Siemens' Rifle Competition.—On Saturday last a shooting match between teams of 17 members each, representing the Ediswan and Siemens' rifle clubs, was decided on the Ediswan range by a win for the home team by 1,234 to 973. Spoons were awarded to Mr. Fowler (Siemens), and Mr. Black (Ediswan) for the highest scores of 97 and 91 respectively. Wooden spoons were also given for the two lowest scores.

SUMMARY

Two articles deal with the new sizes of half-watt lamps which have just been placed upon the market (pp. 294 and 298).

THE action brought by Osram Lamp Works, Ltd., against Pope's Electric Lamp Co., Ltd., is still proceeding (p. 294).

WE give an illustrated description of a 200 h.p. rail car equipped with the Thomas electrical transmission system, destined for New Zealand (p. 295).

A PHENOMENON occurring in the testing of magnetos is discussed in our "Questions and Answers" columns (p. 296).

AMONG the subjects of specifications published at the Patent Office last Thursday are electrical precipitation of dust, etc., from gases, meters, incandescent lamps, transformers, and variable speed motors. A patent for electromagnetic switches is opposed (p. 297).

A 6,000 kw. turbo-alternator, etc., is required at Bristol; mains and services and an alternator at Barking; meters and maximum demand indicators at Melbourne; and machinery oils at Hull (p. 299).

NOTWITHSTANDING the war the accounts of municipal electricity undertakings for the year to March 31st, 1915, which are being gradually published, show on the whole increases in output. At the same time increases in charges are becoming more general, owing to the higher price of coal, labour, etc.—The Edinburgh City Electrical Engineer deprecates refusing to connect new consumers in view of the check this will have upon the development of the undertaking (p. 300).

THE General Electric Co.'s accounts for 1914-15 show a net profit of £138,022, and 10 per cent. is

recommended on the ordinary shares.—No dividend is recommended on the ordinary shares of Crompton & Co. for last year, the balance of £7,691 is carried forward after meeting preference dividend (p. 300).

A Self-closing Circuit-breaker.—A new form of circuit-breaker, which not only opens on overload, but recloses automatically when the short circuit is off, is described in the *Electric Railway Journal*. The main contact brush is moved to the closed position and held closed by the operating coil. In case of an overload the armature of a series coil is raised, and this opens a contact which breaks the circuit of the operating magnet, the latter being held open by a latch until the trip coil operates. After opening the main contact a small index current is permitted to flow around the breakers with high resistance. So long as the resistance of the load circuit is low the index current will be shunted around the trip coil, but if it is increased, enough current will be forced through the low-resistance trip coil to operate the latch and allow the contact arm to close the circuit of the operating coil, thus closing the breaker.

Electrolytic Disinfectants.—A report of the Medical Officer of Health for the Borough of Poplar on the manufacture of disinfecting fluid for the Borough by an electrolytic process records that since the installation of the plant in 1906, 381,794 gallons of fluid have been manufactured at a cost of £401 for electricity and £345 for materials. Various improvements in the plant have been made from time to time, which have improved its efficiency and economy.

Electric Vehicles at the Road Exhibition.—There were several electric vehicles among the exhibits at the National Road Exhibition at the Horticultural Hall last week. Edison Accumulators, Ltd., show a tipping wagon similar to that described in ELECTRICAL ENGINEERING (June 17th, p. 254) in connection with the I.M.E.A. Parade, and also a small electric hoist for short haulage work. The General Vehicle Co., Ltd. (Imperial House, Kingsway) (the leading features of whose cars were also described in the article referred to), took part in the exhibition as well, and showed among other examples of their vehicles an electric 3½-ton chassis equipped with street-watering gear.

The I.E.E. Museum.—The collection of electrical apparatus of historic interest at the Institution of Electrical Engineers is making substantial progress, but is not yet by any means representative of the early days of the electrical industry. The Council invite members and others to help by sending or presenting suitable apparatus which is now out of use. Early forms of electric motors, arc lamps, and measuring instruments are desired, and the Council are in search particularly of a Jablochkoff Alabaster candle-holder.

The late Mr. C. E. Spagnoletti.—At the funeral of the late Mr. C. E. Spagnoletti, Honorary Member and Past-President of the Institution of Electrical Engineers, whose death we recorded in our last issue, at West Hampstead Cemetery last Friday, July 2nd, the Institution was represented by Sir John Snell (President), Professor Carey Foster, F.R.S., Dr. S. P. Thompson, F.R.S., Mr. J. E. Kingsbury, Mr. Roger T. Smith, Mr. H. Hirst, and Mr. P. F. Rowell (Secretary).

Brazil.—We have before us the fourth edition of a handbook on Brazil, just issued (price 7s. 6d.) by Mr. J. C. Oakenfull (c/o Cappelle, 2 Upper Janemount, Cork, Ireland). Although the book is in the main not concerned with electrical or engineering matters, a few pages give brief particulars of some of the hydro-electric power plants, and an indication of some of the conditions to be complied with in obtaining concessions. It appears that there are very large waterfalls still unexploited.

NEW SIZES OF HALF-WATT LAMPS

HERE is already considerable demand for the new sizes of half-watt lamps, advertised by several firms last week. As has been the case in almost every step in improvement in lamp manufacture, the greater benefit is at first obtained by users of low voltage. The private installations at 25 volts, put down in the earlier days after the introduction of the metal-filament lamp, partly to save capital cost of secondary batteries, and partly in order to utilise the smallest candle-powers of metal-filament lamps then available, are now able to obtain a range of half-watt lamps of from 15 to 100 watts. They are fitted with the ordinary bayonet cap, instead of the Edison screw, and are not of abnormal size or shape, the smallest size being 4½ in. long by 2½ in. diameter, and the largest (100 watt) from 6½ to 7½ in. long by 4 in. diameter. In the 50- to 65-watt lamps, of which the smallest size of half-watt lamps has hitherto been 100 watt, 30- and 60-watt lamps are now obtainable. Greater interest will attach, however, to the lamps for ordinary supply station voltages. For 100 to 130 volts there are two new sizes, viz., 60 and 100 watts, measuring about 5½ in. by 3 in., and 6½ in. by 4 in. respectively, and both with bayonet caps. For 200 to 250 volts the new sizes listed are 100, 150, and 200 watts; of these the 100-watt size only is fitted with bayonet caps, the two larger sizes having Edison screw caps. The 100- and 150-watt 200-volt lamps measure about 6½ in. by 4 in., and the 200-watt lamps 8½ in. by 4½ in. The dimensions vary to some extent, according to the different makes of lamps.

All the lamps mentioned are stated to have approximately an efficiency of ½ watt per c.p., so that the candle-powers may be taken roughly as twice the watt ratings. Illustrations of some of the new lamps appear in our Trade Section. It will be seen that in the 100-watt sizes the filaments are in an absolutely horizontal plane, so that the maximum candle-power will be vertically downwards. Argon is, we understand, the inert gas used for filling these lamps.

Considerable progress is being made in the manufacture of half-watt lamps in this country, especially in the larger sizes, but, up to the present, the new sizes appear to be chiefly imported from Holland, under licence. In this connection it is interesting to note that the Dutch and some of the German makers have, for some little time past, been advertising gas-filled lamps of smaller size still at the usual supply station voltages, but investigation will probably show that in nearly all of them the efficiency is by no means half a watt per candle; in some cases it is much nearer one watt per candle. For instance, one German maker announced in the last two June issues of the *Elektrotechnische Zeitschrift* that they have introduced a new gas-filled lamp with a bulb not very different in size and shape from that of the ordinary tungsten lamp, and its filament placed in a horizontal plane; the smallest size in 100- to 130-volt lamps is 40 watts, but the mean spherical candle-power of this lamp is only 45 Hefner, and the candle-power in a line with the axis of the lamp 55 Hefner. The 200- to 250-volt lamps of this type are 75 and 110 watt, having mean spherical candle-powers of 80 and 110 Hefner respectively, and candle-powers in an axial direction of 100 and 140 Hefner respectively.

THE OSRAM v. POPE PATENT ACTION

THE hearing of this case has continued before Mr. Justice Joyce since our last issue. When we went to press last week Sir James Dewar was giving evidence for the Osram Lamp Works, Ltd., and the only other witness called for the plaintiffs in the action was Dr. Otto Oberlander, who also generally confirmed the evidence given by Dr. Passmore.

Mr. H. Colefax, K.C., then addressed the Court. He said there was no contest between the parties that carbon is chemically removed, according to the process used by the Pope Co., but whereas the Pope Co. maintained that the carbon was present in the filament carbide of tungsten, and was oxidised through the agency of the oxygen in the tungsten oxide, the Osram argument was that the carbide or free carbon was removed by the oxygen in the steam. Whether the Judge assumed that the defendants were right or not, there would still be a case for consideration as to whether they escaped infringement. The cross-examination of the plaintiffs' witnesses had raised one or two points on this question of infringement. The Pope Co. seemed to think that the carbonising was a separate and distinct step from any step in which carbon was removed as carbonic oxide. Another point was that the defendants did not

pass a current through their filaments to raise them to a high temperature, but adopted as the source of heat an electric furnace in which they heated the filaments externally, whilst a third point was the suggestion that the Just & Hanaman specification called for a soft paste as contrasted with a hard paste used by the defendants. There was, however, nothing in the specification which tied the patentee down to either form of paste, nor did it matter what method of heating was adopted. The plaintiffs' experiments with the defendants' process had shown the presence of hydrogen and steam at each and every stage of carbonisation, and they got absolutely all that the specification detailed. The defendants had made no attempt to see whether water was present; they had the means for doing so, but had relied entirely upon theory to rebut the case for infringement. The plaintiffs' experiments with the defendants' process, on the other hand, had shown that hydrogen was present and that carbon was being removed.

This closed the case for the Osram Lamp Works, Ltd.

Mr. Hughes, K.C., in opening the case for the defendants, put forward the points that the defendants in their process used a hard paste where the Just & Hanaman specification referred to a soft paste, and that the filaments were heated externally and not by means of passing an electric current through them. This latter, he contended, was an improvement on the Just & Hanaman patent in that it facilitated manufacture because bundles of filaments could be dealt with at once instead of each filament separately. Furthermore, there was greater risk of unevenness in thickness of soft paste filaments. He was not at all sure that this in itself would not have constituted subject matter for a new patent. Again, the hydrogen used in the Pope process was absolutely dry; it was purchased in a moist state, but all the moisture was taken out. When the plaintiffs started their action for infringement in October, 1913, they did not know in the least what the Pope process was, but in 1914 they discovered that the result obtained was not produced by the passage of an electric current through the filaments, and that the hydrogen used was absolutely dry. He could not help feeling that this must have been startling, as also must have been their discovery of the alternative process of manufacture in vacuo. Consequently a number of distinguished men of science had been called upon to find a theory to fit the facts as they were found. The theory which had been put forward was, to say the least, extravagant, for it came to saying that although the defendants used dry hydrogen, and that water was produced in the course of the process, consequently the filaments were treated in an atmosphere of steam and hydrogen. He contended that it could not be put forward as infringement, inasmuch as if any water was produced it was a result of the process, and not a necessary item with which to begin the process.

Dealing with the question of validity of the Just & Hanaman patent, counsel argued that there was no subject-matter for a patent, inasmuch as it merely took tungsten, a metal already known as suitable for the purpose, and applied to it the Welsbach process already known in connection with osmium. Such a combination was not invention within the meaning of the patent law.

Mr. Ballantyne was then examined by Mr. Terrel on processes described in the patents cited as anticipations, and in the Just and Hanaman patent, and particular attention was drawn to the difference between heating the filaments singly by passing current through them, as described in the patent, and heating them in bulk in a furnace, as done by the defendants. The Just and Hanaman process was, he said, practically similar to that of Welsbach, with tungsten substituted for osmium, and the instructions were such that a soft paste was indicated, and not a hard paste as used by the defendants. The defendants used such a small quantity of binder that the carbon played no important part in holding the filament together, and owing to this hard paste, different plant, including a hydraulic press for squirming, a calendar for more intimate mixing, and a continuous acting furnace was used. Nearly all the carbon was removed by the preliminary drying off of the volatile constituents of the binder, so that there was no true carbonising in the first furnace. Examined as to Dr. Passmore's experiments, witness denied that they proved in any way that the plaintiff's theory that the action was due to steam was correct. Again, the experiments to show that tungsten had no direct action on carbon except at very high temperatures were inconclusive owing to the form of the carbon being different. His own experiments under the conditions of the process indicated that a carbide was formed. He succeeded in making filaments, using all the gaseous atmospheres described by Welsbach, but had failed to produce them on the soft paste system, which the Just and Hanaman specification appeared to indicate.

The case was still proceeding when we went to press.

Obituary: *Killed in Action.*—The Chesterfield Corporation Electricity Works have suffered a great loss by the death of Mr. T. E. Bennett, Second Assistant Engineer, who was killed in action on Wednesday last week. Mr. Bennett, who was 33 years of age, had been with the Corporation for nearly 10 years, and together with several other members of the staff joined the 6th Notts and Derby's in November last, and proceeded to the front in February.

A 200 H.P. RAIL COACH WITH THE THOMAS TRANSMISSION

OUR readers are already familiar with the ingenious combined mechanical and electric transmission gear known as the "Thomas Transmission," which has been applied not only to petrol-engined touring cars and heavy commercial vehicles (see ELECTRICAL ENGINEERING, May 4th, 1911, p. 236), but also to rail-coaches propelled by internal combustion engines (see ELECTRICAL ENGINEERING, November 7th, 1912, p. 627). The system is such as to give almost the equivalent of a continuously variable ratio gear, with the result that the engine can be always running at its most efficient speed, and the carburettor can be set for economy rather than flexibility, so that figures of fuel consumption have been obtained markedly lower than by any other system. This fact was emphasised in the case of the road vehicles by the award of the R.A.C. "Dewar Trophy" in 1911 and the results of tests of the 160-h.p. rail coach supplied (in conjunction with Leyland Motors, Ltd.) to the South African Railways five years ago. It was the successful results with this coach that led to the New Zealand Railway authorities determining to give the system a trial, and the chassis of a 200-h.p. coach which is complete and ready for shipment

is thus locked solid with the engine, so that when the battery provided for the purpose is connected across the series machine C the engine is caused to rotate and starts up. In order to understand the action of the gearing, let it be assumed that both clutches are disengaged. When the engine drives the casing B a differential action is set up between the large sun wheel and the small sun wheel. The large sun wheel tends to rotate forwards in the same direction as the engine and the small sun wheel tends to rotate backwards in the opposite direction to the engine. If the clutch E is engaged, then the large sun wheel will be held stationary as it is connected direct to the load, and as the small sun wheel is free, it will rotate backwards at about the same speed as the engine rotates forwards. If current is taken from the machine C the motion of the small sun wheel will be retarded, so that the large sun wheel, i.e., the load, must begin to move. By manipulation of the field of the machine C this action can be continued until the small sun wheel is practically brought to rest, and the large sun wheel caused to rotate at about half engine speed. During this initial period the current from the machine C is transmitted to the motor, driving the second bogie electrically. It is clear, therefore, that there is a mechanical drive to the first bogie and an electrical drive to the second bogie. The next operation is to increase the speed of the large sun wheel gradually until it reaches the engine speed, so that the gearing can be locked solid by means of the clutch F, and a "direct" drive obtained for top speed. This speeding up of the large

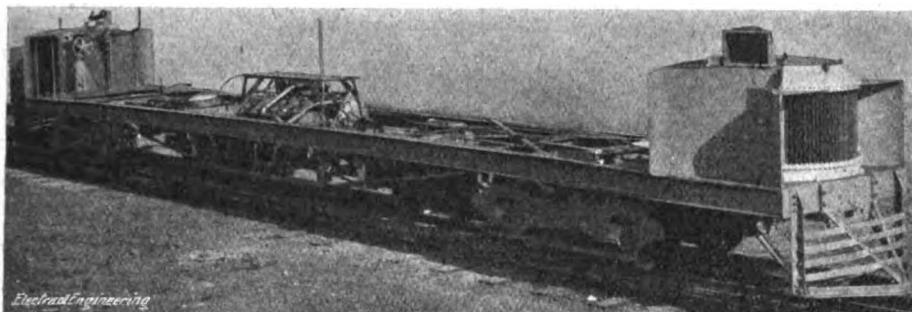

FIG. 1.—COMPLETE CHASSIS OF 200 H.P. RAIL COACH.

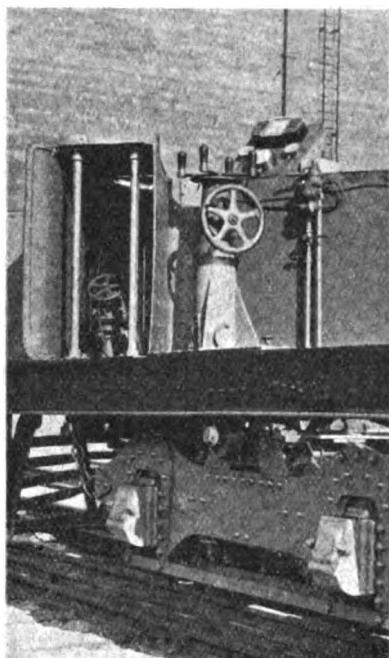

FIG. 3.—CONTROL APPARATUS.

was recently shown running to a party of engineers and Press representatives. The complete chassis is shown in Fig. 1, and further details of the control gear can be seen in Fig. 3. The coach is driven by a 200-h.p. eight-cylinder engine made by J. Tylor & Sons, Ltd., running at from 900 to 1,500 r.p.m., and situated in the centre of the vehicle. This is coupled to the electro-mechanical apparatus shown in Fig. 2, and with certain covers removed and diagrammatically in Fig. 4. This forms the first part of the Thomas transmission gear proper, and the shaft D drives one bogie through universal joints and a bevel and spur reduction gear. The other bogie is driven in circumstances detailed more fully below by an electric motor only through a similar cordon shaft, this motor taking current when in use from the dynamo C (Fig. 4).

The variable ratio drive is obtained in the following manner:—The engine shaft is permanently connected to the casing B, which carries a set of planet wheels on two spindles which are supported in roller bearings in the sides of the casing. Each spindle has rigidly fixed to it two planet wheels of different diameters, and these in turn mesh with two sun wheels. The larger sun wheel drives the shaft D through the free-wheeling magnetic clutch E. The smaller sun wheel is connected direct to the armature of the electrical machine, and a magnetic clutch F is provided for locking the planetary gearing. In order to start the engine, the clutch E is disengaged, and the clutch F engaged. The electrical machine C

sun wheel from half speed to top speed is obtained by changing the functions of the two electrical machines, and causing the motor in the other bogie to act as a generator and supply current to C as a motor, driving the latter in the same direction as the engine. This operation is a gradual one, and is carried out by manipulation of the field of the motor. When the sun wheels and the casing have reached a common speed, the magnetic clutch F is engaged, so that the electrical transmission is cut out altogether and a direct drive obtained from the engine to the first bogie.

It is important to notice that with this arrangement the adhesion of the driving wheels on both bogies is made use of during acceleration when the tractive effort is greatest, although on top speed the drive is by one bogie only. As the vehicle has to travel equally well in either direction, it is necessary to provide a reversible engine, but for shunting and reversing for very short distances an emergency reverse is provided, which works in the following manner:—The clutch E is disengaged and the clutch F engaged, so that the machine C is locked solid with the engine. Current is then taken from this machine as a generator to the machine on the other bogie acting as a motor with a reversed field, and the vehicle driven purely electrically from the second bogie in the opposite direction. The battery is quite small, being only used for starting the engine and lighting the vehicle, and is charged when the car is running on top speed and the electrical machines are not contributing to the drive.

The chief advantages claimed for the system compared with those of other electrical transmission gears are the low cost of

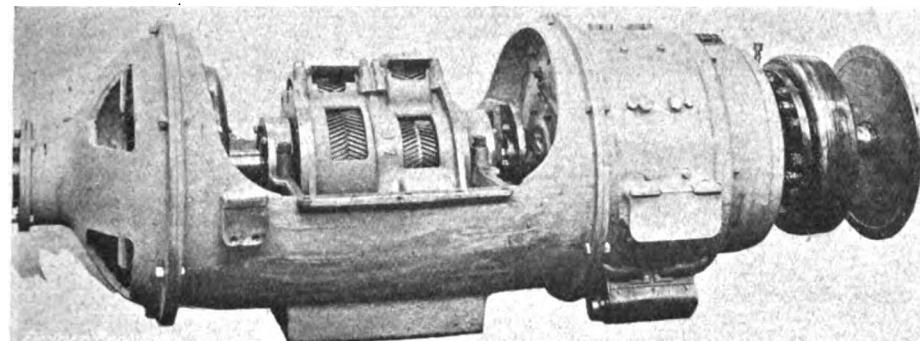

FIG. 2.—THOMAS TRANSMISSION GEAR.

the electrical equipment, high efficiency, and simplicity of control. The electrical machines only transmit a portion of the power from the engine, and are only in action when the vehicle is accelerating or climbing gradients. The result is that they can be smaller than is possible with any other system. The high efficiency obtained is due to the fact that a direct drive is provided for top speed, and on all the lower speeds most of the power is transmitted to the load direct mechanically through the large sun wheel. The control is remarkably simple as it is purely electrical, and is obtained by manipulation of the fields of the two electrical machines and the excitation of the two magnetic clutches, and as we have already remarked, a very large number of controller stops can be obtained.

This chassis will have a 50-seated body mounted thereon, and two 25-ton trailers will accommodate a further 50 pas-

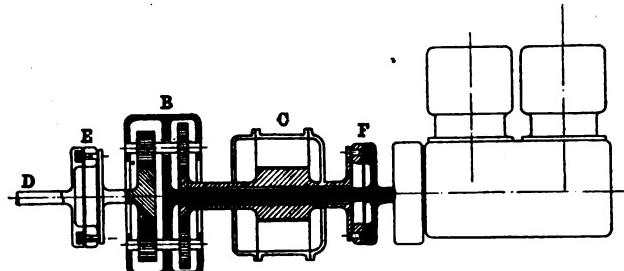

FIG. 4.—DIAGRAM SHOWING ARRANGEMENT OF TRANSMISSION GEAR.

sengers each. On the level its maximum speed will exceed 40 m.p.h., and it will haul one trailer of a 1 in 40 grade at 28 m.p.h., or both at 10 m.p.h. The fuel consumption on a give-and-take road is expected to be within one gallon per 200 ton-miles.

It will be remembered that in the road vehicles fitted with the system the second electrical machine was mounted on the equivalent of the shaft D (Fig. 4), contributing to the drive of the same wheels when in use, but otherwise the system is identical. Another use to which the system is being adapted is the propulsion of a road train. In this case the engine's first electrical machine and planetary gear is on the tractor, while the trailing vehicles are all electrically-driven to a greater or less extent on the lower speeds, but not when the top speed is attained and the direct drive is in use.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,450.

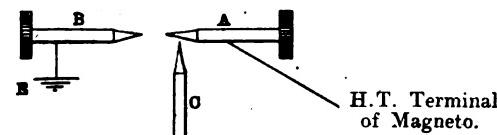

I am in charge of the electrical plant at a large works. The current is supplied to us through a 1,200-kw. 6,000-500-volt three-phase transformer, and drives a large number of induction motors. The star-point of the transformer is not earthed. I have tested all motors and feeders to earth with the megger, and I get a good test; but when I put the current on, I get a faint glow on two 220-volt lamps connected in series from all three phases to earth. I afterwards placed one 220-volt lamp across each phase to earth, but I only got the same faint glow.

I then switched the current off the transformer, and I tested the low-tension side of transformer when in circuit with ten feeders and distribution-boxes up to the motor switches. I got a test of 600,000 ohms on all phases to earth. The current was then switched on the feeders, but I still get the same faint glow on the lamps as before. The question is: Why do I get a glow on the lamps, and why only the same glow on the single lamp? If there is leakage to earth there must be a short on at least two phases through earth, but I have no fuses blown.—"PELICAN."

(Replies must be received not later than first post, Thursday, July 15th.)

ANSWERS TO No. 1,448.

It is the custom in testing magnetos to connect the high-tension terminal through a spark gap to earth, the gap being such as that shown on the accompanying diagram, the points

being lettered A and B. It is found, however, that when a further point, C, insulated from both of the others, and from earth, is introduced, as shown, the magneto sparks much more readily. What is the explanation of this?—"RADIAUM."

The first award (10s.) is given to "L. R." for the following reply:—

The action of the auxiliary discharge assister will be best understood by considering a modified form on which it is based. If a discharge is taking place between the ends of two wires connected with the poles of an induction-coil, the ends of the wires being at such a distance that the spark passes freely, then if an insulated wire be so placed that one end is near the positive terminal, and some other point on the wire is almost touching the wire leading to the positive terminal, the length of the spark is greatly increased. A wire similarly placed with regard to the negative terminal has no effect, if the condenser is properly adjusted. The ratio of the increase depends upon the shape of the terminals, but the actual length of the spark tends towards a maximum almost independent of the shape of the ends. Also, if an insulated wire be placed at right angles to the negative wire, near its terminal, the length of the spark is similarly increased—to some extent if touching the negative wire, to a greater extent if almost touching. This is the arrangement referred to. It is, of course, incidental that a magneto is used instead of an induction coil, the same results being obtained on the corresponding half waves.

The explanation is probably that the action of the negative assist is due to the attraction of the negative electrons in the assist and discharged from the assist on the positive electrons. When the negative assist is impulsively charged across its spark-gap this causes an induced impulsive rush in the positive wire, causing the positive electrons to leave the terminal with greater velocity. The effect on the negative assist is probably added to by a discharge of negative electrons from its point when it is impulsively charged. This negative discharge from the point is in an effective position to act attractively upon the positive electrons, and endures long enough to produce its full effect. When the negative assist is surrounded by an insulator, or when a sheet of vulcanite is brought up close to its point, the negative discharge is either entirely prevented or is quickly re-absorbed.

This matter is discussed at some length in a Paper by T. J. Bowlder in the *Philosophical Magazine*, Vol. 8, p. 487, 1904, and details of the variations of the spark length under certain conditions are given therein. The phenomenon has also been employed by Williams in the spark-gaps for Hertzian transmitters and the like, and he explains it on the ground that the assisting electrode forms a circuitous shunt for the discharge of a small fractional part of the whole of the electric energy, very minute sparking being maintained between the assisting electrode and the adjacent electrode, the stem of the assist serving to collect the distributed invisible discharges between itself and the remote electrode. He leads up to this by first taking the case of an assist which bridges across the gap, but does not touch either electrode, gradually coming to the form in which the assist is at right angles to the path of the spark, one end being close to one electrode (see British Patent No. 175 of 1903). Williams also proposes to use the device for ensuring the ignition sparks in internal combustion engines.

The second award (5s.) is made to "P. R. C." who writes as follows:—

The phenomenon described by "Radium" is one that is not confined to the testing of magnetos, as it is apparently merely a variation of the discovery originally made by Hertz as long ago as 1887 that the impact of ultra-violet light upon a spark-

gap which is on the point of breakdown has a stimulating action upon it, and facilitates the passage of the spark discharge. In the case described very minute sparks would pass to the insulated side point, and these being so close would easily influence the main spark, and cause the discharge to pass more readily. The use of a point for the side electrode would facilitate the passage of these side sparks more than would be the case if a knob were used. In addition to the above, a slight action would in all probability be due to the close proximity of the side sparks causing the main spark-gap to become slightly

ionised. This would again facilitate the passage of the main discharge.

Question No. 1,446.—A correspondent has pointed out an error in the diagrams in Figs. 1 and 2 in the published answers to the question on p. 280 of our issue of June 24th. The letters *A* and *L+* on the starter terminals should be interchanged so that the positive line connection is brought to the starter arm and armature terminal to the last resistance stop. This brings the connections in line with those in Fig. 3.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 1st, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

18,357/13 and 19,732/13. **Precipitation of Dust, Smoke, &c.** E. MÖLLER. Methods of separating suspended solid particles from gases by the presence of charged electrodes. In the first method a grid is used of alternating ionising electrodes in the form of rods, with saw-like toothed edges, and non-ionising electrodes of strip form. In the second, the gases are passed through parallel cylindrical tubes with a high-tension electrode in the form of a wire down its centre. (Four figures and two figures.)

6,341/14. **Meters.** SIEMENS-SCHUCKERT WERKE G.M.B.H. Induction meters maintaining the straight line relation between the load and the speed of the armature at light loads by shunting a variable proportion of the lines of force generated in the field coils by suitably dimensioned magnetic masses which begin to be saturated before the higher values of the load are reached, and are placed so as to deflect the lines of force from the armature. (Two figures.)

8,684/14. **Incandescent Lamps.** ELECTRIC UTILITY Co. and R. W. LONG. A device for winding filaments of incandescent lamps, comprising a block or thimble adapted to be mounted temporarily on the stem of the lamp, and carrying stout wires or like supports so situated that when the block or thimble is in place, there is a wire or support in such relationship to each of the flexible hooks on the stem of the lamp that the filament can be wound on a horizontal portion of the wire or support, and afterwards slipped therefrom into the hook. (Two figures.)

14,030/14. **Transformers.** F. E. BERRY. Improvements in transformers of the class in which laminated iron strips are placed between the primary and secondary windings to provide a shunt path for the leakage flux in cases where high reactance is desired. According to this invention the shunt path is constituted by a series of laminated iron strips arranged in groups separated by air gaps, the air-gap separation proceeding in a direction axial on both circumferential and axial to the transformer windings. (Three figures.)

14,415/14. **Variable Speed Motors.** H. H. JEFFCOAT. Means for varying the speed of A.C. motors, consisting in a combination of a commutator connected directly to the windings of the stator or rotor or commutator, connected to both, and brushes capable of rotation driven by a variable speed or other mechanism. (Two figures.)

20,549/14. **Cables.** C. J. BEAVOR and E. A. CLAREMONT. A high-tension cable designed to increase the cross section of the conductor so as to minimise stress on the insulation without using more copper than is necessary for conduction. The conductor is composed of a hollow metal core with metal strands stranded or braided thereon, and a metal tube forming the outside of the metal strands. The core and tube may be of lead or other suitable pliable metal, and the metal strands of copper. (One figure.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

DYNAMOS, MOTORS, AND TRANSFORMERS: BRESLAUER [Alternators] 19,445/13; KLEINER [Motors for shaking shoots] 20,776/13; BRITISH WESTINGHOUSE Co. [Dynamos] 4,560/15.

Heating and Cooking: BERRY [Heaters] 14,469/14.

Ignition: HEINS and WILD [Ignition system] 6,992/14.

Instruments and Meters: A.E.G. [Coil bobbin for instruments] 21,959/13.

Switchgear, Fuses, and Fittings: A.E.G. [Oil switchgear, &c.] 23,348/13; B.T.-H. Co. (A.E.G.) [Regulators] 7,007/14;

WINEBERG and PARKER [Conduit continuity device] 14,163/14; MANSON [Conduit fittings] 14,392/14; ELLISON [Circuit-breakers] 16,984/14; DICKINSON and OPTALYTE, LTD. [Hand lamp] 19,679/14; HEMMING and BECK [Conduit fittings] 19,908/14; B.T.-H. Co. (A.E.G. Co., U.S.A.) [Rheostats] 19,943/14 and 20,129/14; R. BOSCH [Electromagnetic switch] 20,927/14; SCLATER [Conduit fittings] 24,742/14.

Telephony and Telegraphy: SIEMENS & HALSKE A.G. [Automatic telephones] 23,336/13; STILLE [Telegraph or telephone relay] 7,200/14; [Electric transmission of sound] 7,202/14 and [Microphones] 7,203/14; SIEMENS BROS. & CO. and PETTITHORPE [Automatic telephones] 7,208/14; SIEMENS & HALSKE A.G. [Semi-automatic telephones] 7,327/14; SCHIESSLER [Wireless telegraphy and telephony] 11,708/14; BURFEIND [Telephone systems] 14,808/14; GREEN [Telephone switches] 15,125/14; SCHNEIDER and STOLZ [Telephones] 19,538/14.

Traction: NUSSER and MILES [Signalling] 20,824/13; MIDGLEY and VANDERVELL [Engine starters] 21,782/14.

Miscellaneous: B.T.-H. Co. (A.E.G.) [Mercury-vapour rectifiers] 21,574/13; ZEHDEN [Burglar alarms] 7,266/14; HEIMROD [Mercury-vapour rectifiers] 13,973/16; SIEMENS SCHUCKERT-WERKE GES. [Electrically-driven drilling machine] 14,021/14; EHRLHART [Condensers] 14,793/14; GREEN and LANDON [Mining signals] 20,342/14; PORDES [Batteries] 1,530/15; MARSHALL [Air heaters for thermopiles] 7,283/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Telegraphy: AGNER [Wireless telegraphy] 6,217/15.

Traction: R. BOSCH [Engine starters] 20,928/14, and [Car lighting] 5,184/15.

Miscellaneous: Soc. ANON. DES ETABLISSEMENTS L. BLÉRIOT [Electromagnetic make-and-break device] 8,770/15.

Petition for Restoration of Lapsed Patent

10,675/10. **Reinforced Concrete Telegraph Posts.** R. ESPAZA. A petition has been lodged for the restoration of this patent, which had been allowed to lapse owing to non-payment of renewal fees. The specification describes a method of constructing hollow concrete telegraph posts on a reinforcing framework of upright rods and helical wires.

Opposition to Grant of Patent

22,435/14. **Electromagnetic Switches.** T. E. BARNUM and W. E. DATE. Opposition has been entered to a grant on this application. The specification describes electromagnetic switches or contactors of the lock-out type controlled by separate and opposing electromagnets energised by a common current, which, if it does not exceed a predetermined value, operates to close the switch; but, if it does exceed that value, prevents the closing of the switch.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: A. D. JONES [Enclosed flame arc lamps] 5,829/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: J. LUNDGREN [Braiding machines] 6,646/02; J. STRATTON and E. A. CLAREMONT [Cables] 6,151/09.

DYNAMOS, MOTORS AND TRANSFORMERS: A. J. BOULT [Testing insulation of wire while winding field coils] 6,099/06; L. J. HUNT and SANDYCROFT FOUNDRY Co. [Cascade windings] 6,223/06; G. WESTINGHOUSE [Ventilation of turbo-generators] 6,118/07; B. T.-H. Co. (G.E. Co., U.S.A.) [Compensating windings] 6,649/07; [Motor control] 6,564/09; and [Motor speed indicator] 6,673/09.

Instruments and Meters: D. COX [Resistance measurement by electrometer] 6,193/02.

Switchgear, Fuses and Fittings: B.T.-H. Co. (G.E. Co., U.S.A.) [Contactor controllers] 6,528/07.

Miscellaneous: D. K. MORRIS and G. A. LISTER [Long stroke magnets] 6,083/07; MAVOR & COULSON, S. M. and H. A. MAVOR [Coal cutters] 6,051/09.

"ELECTRICAL ENGINEERING" TRADE SECTION

NEW SIZES AND PRICE REDUCTIONS IN HALF-WATT LAMPS

SEVERAL firms have sent us lists and particulars of the new sizes in half-watt lamps, and have also reduced the price of some of the sizes hitherto on the market.

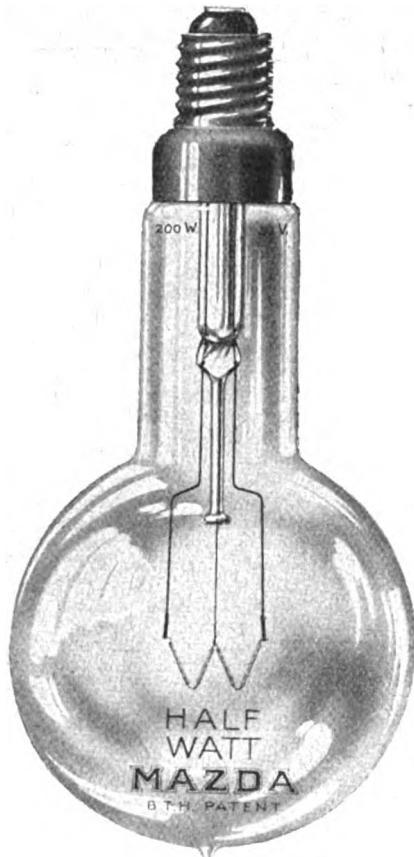

FIG. 2.—200-WATT LAMP.

It will be useful to give a complete list of the sizes of these lamps now obtainable. Those in italics are new sizes:—

25 volts:—15, 30, 60, and 100 watts. All bayonet caps. Prices from 4s. 6d. to 12s. 6d.

FIGS. 1 & 1A.—100-WATT MAZDA LAMP AND SKETCHES SHOWING SHAPE OF FILAMENT.

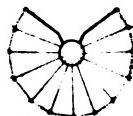

FIG. 1.—100-WATT MAZDA LAMP AND SKETCHES SHOWING SHAPE OF FILAMENT.

Bayonet caps for the 100 watts, Edison screw caps for the 150 and 200 watts, and Goliath screw caps for the remainder. Prices from 12s. 6d. to 50s.

FIG. 3.—SPECIAL PROJECTOR LAMP.

Mazda Half-Watt Lamps.

The British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), issues its list in the form of an attractively got-up catalogue containing general particulars with regard to the lamps and their scope, and some illustrations showing effective lighting by half-watt lamps. We reproduce three illustrations of the lamps themselves: Figs. 1 and 1A show the 100-watt size with a plan underneath showing the shape of the filament; Fig. 2 is a 200-watt lamp; and Fig. 3 is a special projector lamp with grid filament in a vertical plane and one side of the bulb silvered. At present the latter lamp is only obtainable for 100-130 volts, and in sizes from 300 to 1,500 watts.

Royal Ediswan Half-Watt Lamps.

The Edison list (The Edison & Swan United Electric Light Co., Ltd., Ponders End, and 123-5 Queen Victoria Street, E.C.) includes an excellent picture, which we reproduce (Fig. 4), of the 100-watt lamp, showing clearly the shape of the filament. The list is in the form of a four-page sheet, which is well arranged and practically confines itself to the essential details of sizes, &c.

Wotan Half-Watt Lamps.

Like everything published by the Lamps Department of Siemens Bros. Dynamo Works, Ltd. (38 and 39 Upper Thames Street, E.C.), their new catalogue of Wotan half-watt lamps is distinctive. Besides complete technical and business details, they include in it pictures of stage, railway station, and bank lighting.

Osram "Atmos" Type Lamps.

"Atmos" is the name now given by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), to the Osram half-watt lamp. The voltages and wattages and caps are those already mentioned, but the distinctive feature of the leaflet issued by

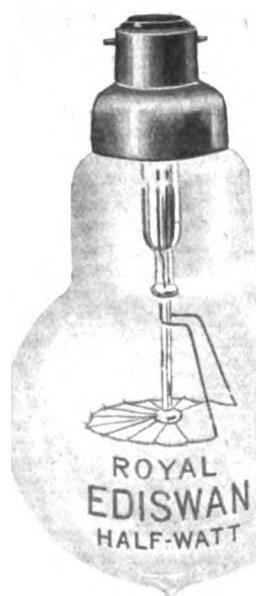

FIG. 4.—100-WATT LAMP.

50-65 volts:—30, 60, 100, 150, 200, 300, and 500 watts. Bayonet caps from 30 to 100 watts, Edison screw caps for 150

this maker is that it is stated that the lamps are made at Hammersmith.

Drake & Gorham Lamps.

Messrs. Drake & Gorham, Ltd. (1 Felix Street, Westminster, S.W.), have printed their list of half-watt lamps in three different forms, destined for practical use. One is in the form of a letter to the contractor, another is a hanging card of convenient size and shape, and the third is a neat pocket folding leaflet for the pocket book, giving, in addition to the list, a few "selling points" briefly and tersely put. Lamps of new sizes and prices are conveniently indicated by red type.

Other matter with regard to the new half-watt lamps will be found in an article on p. 294.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Australia.—The Melbourne City Council requires 1,381 meters and 75 maximum demand indicators. Tenders by July 27th to McIlwraith, McEacharn & Co., Biliter Square Buildings, London, E.C.

Barking.—In reference to the Council's application for a loan of £18,000 the L.G.B. has sanctioned £1,376 for mains and services and £117 in respect of an alternator and transformers. As regards the remainder, the decision of the Board is deferred until revised estimates have been prepared.

Bristol.—A L.G.B. inquiry was held last week concerning a loan of £27,295 for the purposes of the electricity undertaking. Of this amount a 6,000-kw. turbo-alternator, &c., represents £26,949, and the balance is for excess of expenditure over existing loans. The Inspector was informed that the estimated extra demand of 2,174 kw. added to the present load of 4,947 kw. would leave a margin of only 2,715 kw., or rather less than the full capacity of one of the largest units of plant, viz., 3,000 kw. This, it is felt, is an insufficient margin, and hence the desire to instal a new generating set. The Bristol Ratepayers' Association opposed the loan on the ground that there is no real need for it at present. The offer was made to the Corporation to call in an independent electrical engineer to value the existing plant, the argument being that if it is all in good condition the new plant is not required. This inspection the Ratepayers' Association offered to pay for. In reply it was stated that the Corporation feels the need of being in a position to supply as much current as possible for the large amount of munitions which are being made in the district.

Hull.—Machinery oils for electricity works and sub-stations. Acting City Electrical Engineer. July 22nd.

Manchester.—Street electric lighting extensions in Oldham Street.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Manchester.—Shop property and commercial premises. Architect, J. B. Thorley.

Wednesbury.—Extensions to municipal offices, public baths, and new education offices.

Miscellaneous

Australia.—The Victorian Railway Commissioners, Spencer Street, Melbourne, require 20 miles of vulcanised rubber electric light cable. Further particulars at 73 Basinghall Street, E.C.—The Deputy Postmaster-General, Adelaide, requires magneto bells, trembling bells, switchboard cable, and lead-covered paper-insulated cable. British firms may consult specification at 73 Basinghall Street, E.C.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Winchester.—Messrs. Ferranti, Ltd., have received a contract for twelve months' supply of prepayment meters.

APPOINTMENTS AND PERSONAL NOTES

Mr. J. Shepherd has now taken over the Consulting Engineering practice of Shepherd & Watney (32-34 Greek Street Chambers, Leeds), and hopes to make the inspection of plant a particular feature of his future work, in addition to the other activities of the firm. Mr. Watney will continue his interest in the practice in an advisory capacity. Mr. Shepherd has left the L.C.C. tramways after 13 years' service with them; for eight years he was Chief Assistant Electrical Engineer, and since 1910 has had entire charge of the electrical work of that undertaking. During the previous fifteen years he had held responsible positions with leading manufacturing companies.

A switchboard attendant is required in the Leek Electricity Department. Salary 30s. per week.

The Birmingham Corporation Electricity Department requires sub-station attendants. (See advertisement on another page.)

A switchboard attendant is required by the Mexborough & Swinton Tramways Co. (See advertisement on another page.)

Engine-drivers and electric light attendants are required at the Aghada Camp, County Cork. Applications in writing to the Officer Commanding R.E., at the Camp.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Sons, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £93 to £94. (Last week, £94 10s. to £95 10s.)

Australian Agencies.—A firm in Queensland desires to represent British manufacturers of electric lamps. A Melbourne firm desires to represent British manufacturers of electrical goods. Further particulars at 73 Basinghall Street, E.C.

Companies Struck Off Register.—The names of the following will be struck off the Register of Joint Stock Companies in three months' time unless cause is shown to the contrary: British Automatic Telephone Syndicate; Consolidated Electric Works & Appliances; "Electricity," Ltd.; Haywards Heath Electric Supply Co.; Pacific Radiotelegraph Co.; Premier Electric Control; Radio & Electric Power Co.; Tramways Construction Syndicate; Tungsten Metal Co.; United Electrical Construction Syndicate.

"Westool" Electric Tools.—The Westminster Tool and Electric Co., of Suffolk House, Laurence Pountney Hill, Cannon Street, London, E.C., inform us that they have discontinued the use of the name "Vulcan" in connection with their electric tools. In future these portable electric drills, blowers, and lifting magnets will be known by the registered trademark "Westool."

"Thermoid" Flexible.—In the discussion at the Point Five's meeting on June 17th, Mr. A. S. Blackman (Chief Electrical Engineer, Sunderland), referred to a new type of flexible wire which he had found particularly satisfactory for electric irons and other heating apparatus. This is known as Thermoid flexible, and is made by W. T. Henley's Telegraph Works Co., Ltd. It is constructed with a special heat-resisting insulation, and with a flame-resisting external covering. It is designed to combine flexibility with strength, and not to kink. From samples which the firm have kindly sent us we find that cotton is used between a special rubber compound and the copper in the 4-ampere size the tinned copper is stranded as three strands of 7-strand wire, and in the 10-ampere size as seven strands of 7-strand wire. The outer braiding is impregnated effectively with a flame-proof composition, and the wire should combine strength with sufficient flexibility, which is the desideratum for electric irons and heating and cooking apparatus generally.

LOCAL NOTES

Eastbourne: *Electricity Accounts.*—Whilst there was a slight reduction in the revenue from private lighting last year, that from power increased almost sufficiently to counterbalance this loss. There was also an increase in the consumption for heating, but a slight decrease in that for cooking, but it is anticipated that during the coming year this latter will increase, as two large cooking outfits were being installed.

Edinburgh: *War and the Electricity Department.*—Mr. F. A. Newington, the City Electrical Engineer, has reported that it will be impossible for him to release any further members of his staff, having regard to the needs of the Department. So far as new works were concerned, the laying of new mains might be delayed, but he did not think it advisable to refuse to connect new consumers, having in mind the check this would have upon the development of the undertaking. The Corporation is well forward with the arrangements for supplying a number of parishes outside the existing limits, and here again Mr. Newington does not think it advisable to reduce the number of men employed on the mains to any extent during the next three or four months.

Exeter: *Electricity Profits.*—The net profit of £1,554 upon the electricity undertaking is to be carried forward rather than any proportion of it being transferred to relief of rates. The object of this is that the Committee hopes by this means to be able to carry through the current year without an increase in the price of current, notwithstanding the heavy extra expenditure which will undoubtedly be incurred.

Middlesbrough: *Electricity Profits.*—The gross profits on the electricity undertaking last year were £11,000 compared with £11,741 in the previous twelve months. Out of the net profit a sum of £2,000 has been allocated for the relief of rates. Thirty per cent. of the regular staff of the Department have joined the forces.

Leeds: *Large Increase in Sales.*—The report of the electricity undertaking for the year to March 31st shows, unlike so many other towns during the past year, an unprecedentedly large increase in sales to private lighting consumers, the number of units sold being 11 per cent. greater than in the preceding year, and the income 10 per cent. greater. An interesting effect, however, of the use of metal filament lamps is that the income from this source is now £3,065 smaller than it was in 1907-8, although the number of lighting consumers has grown from 5,504 to 10,759. The necessity for restricting expenditure upon services has kept off the mains a number of consumers desirous of coming on. What is called a tariff for "residential bulk supplies" has been fixed, but this is none other than the rateable value system with a charge of $\frac{1}{d}$. per unit. The net profit for the year was £24,224, but owing to the large amount invested in permanent works out of the year's profits, viz., £12,053, the amount allocated to relief of rates is reduced from £14,315 in the previous year to £12,171.

London: St. Pancras: *Increased Charges.*—The electric lighting charges are to be increased by 10 per cent.

Lytham: *Bulk Supply.*—It is possible that arrangements will be come to for taking a supply in bulk from the St. Anne's Council. A preliminary agreement has been made for entering into a contract for ten years.

Nottingham: *Increase in Charges.*—A 12 $\frac{1}{2}$ per cent. increase in the present charges for electricity is to be made in consequence of the advance in the price of coal, &c.

Oldham: *Electricity Accounts.*—There was a net profit of £3,550 on the working of the electricity undertaking last year. The total number of units sold increased by 927,058, or 13·13 per cent. In connection with the scheme of extensions which was sanctioned by the L.G.B. in December, tenders have been accepted for the supply of two 3,000 kw. British Westinghouse turbogenerators, three B. & W. water-tube boilers, two water-cooling towers, extensions to the Ferranti E.H.T. switchboard, and a new battery house and battery.

Redditch: *Electricity Accounts.*—In presenting the accounts of the Electricity Department for the past year, which show a loss of £2,508, the Chairman of the Committee pointed out that although there has been an average loss of £2,662 per year during the past three years, the actual position of the undertaking has materially improved. He also drew attention to the fact that a sum of £3,000 had been spent out of revenue on works of a capital nature.

Stoke-on-Trent: *Improved Electricity Position.*—The electricity accounts for the past year show that the net loss of

£6,162 in 1913-14 has been turned into a profit of £71. There is an accumulated deficit of £6,819 standing in the accounts of the Department. The very substantial progress which the undertaking has made is due to the re-arrangement in conjunction with the new power station which has been carried out under Mr. Yeaman's direction. Last year 10 $\frac{1}{2}$ million units were generated, compared with 9 million units in the previous twelve months, yet the coal bill was less by £2,800.

Walsall: *Electricity Accounts.*—The net profit for the year was £1,385. The question of increasing the charge to consumers is under consideration, having regard to the general increase in working costs due to coal, &c. Much depends upon whether the new power station is completed in time for the coming winter. So great has been the delay with the new power station that the Borough Electrical Engineer declines to take responsibility for dealing with the load next winter should the new plant not be available, and the Committee has been faced with the suggestion of purchasing plant for the existing works at a cost of £1,000 to deal with the winter load. This, however, the Committee is not prepared to do, and it prefers to trust to there being no accident, in which case it is believed the winter demand can be met.

Worcester: *Maintenance out of Revenue.*—In reporting a slight decrease in the revenue last year compared with the previous twelve months, and a net profit of £961 after meeting capital charges, Mr. C. M. Shaw, the Borough Electrical Engineer, points out that the policy of effecting improvements and works of a capital nature out of revenue renders it practically impossible to show large net profits. He also reminds the Council that the value of this policy is now demonstrating itself, as had it not been adopted the position of the undertaking would have been serious at the present time owing to the increased cost of labour, fuel, and other materials.

COMPANIES' DIVIDENDS, REPORTS,
MEETINGS, &c.

Crompton & Co.—The report for the year to March 31st, 1915, shows a net profit of £28,649. The sum of £6,500 is to be placed to reserve, £3,500 to special depreciation account, £1,608 is written off preliminary expenses, and after meeting the full dividend on the 7 per cent. preference shares, a balance of £7,691 is carried forward. The Company's works continue to be fully employed, a large amount of Government work being done.

General Electric Co.—In spite of the war, the total income for 1914-15 was £164,877, against £157,893 in the previous year. After setting aside £18,855 for depreciation, and £8,000 for debenture interest, a net profit of £138,022 remains. The preference dividend absorbs £38,681, and a dividend on the ordinary shares at the rate of 10 per cent. per annum is recommended the same as for the previous twelve months. Reserve is credited with £20,000, and after meeting sundry other items a balance of £36,701 is carried forward. The cable business which the company has started in conjunction with Messrs. Pirelli, of Milan, is progressing, the works at Southampton having been completed during the year. Considerable work is naturally being done for the Government, but the report points out that although the great majority of the company's products are essential for war purposes, the outlook for the year is one of some uncertainty. Nevertheless, the company, from a perusal of the accounts, is in a strong financial position to meet any troublesome period that may come along.

Edmundsons' Electricity Corporation.—After meeting the dividend on the preference shares, the profits last year permit of £10,000 being transferred to reserve, and £3,365 carried forward.

Manufacture of Cables in Norway.—The *Anglo-Norwegian Trade Journal* states that before the war, Germany exported almost all sorts of electric cables and wires to Norway. The import was free of duty for the finished goods, while Norwegian factories in this branch had to pay duty up to 10 per cent. of the value for raw materials. There were, therefore, no possibilities for a Norwegian industry until the war stopped all export of German cables, and the Norwegian factories got an opportunity which they at once seized. In Drammen there is a factory for copper wire, "Elektrisk Industri," and a cable factory "Norsk Kabelfabrik," while in Christiania there are the cable factories "Elektrisk Bureau" and "Norsk Elektrisk Kabelfabrik."

Glover's Almanac.—There are not only many items of useful technical information, but also many sparks of wit expressed in literary and pictorial form in the well-known daily tear-off almanac now issued by W. T. Glover & Co., Ltd., for the fourteenth time, and covering the period from June, 1915, to June, 1916, a time fateful in the destiny of nations.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

SUMMARY

THE fourth list of members of the Institution of Electrical Engineers on active service brings the total up to 1,083 (p. 302).

SOME notes on the forthcoming sessions of technical colleges, etc., are given (p. 302).

SOME descriptive particulars are given of the two 1000 kw. Ljungström turbo-alternators recently installed at the Luton Electricity works (p. 303).

THE hearing of the patent action between Osram Lamp Works, Ltd., and Pope's Electric Lamp Co. was concluded on Tuesday. Judgment was reserved (p. 304).

A PROBLEM on the regulation of a plating dynamo is propounded in our Questions and Answers column (p. 304).

AMONG the subjects of specifications published at the Patent Office on Thursday, were high frequency alternators, voltage regulators, telephone relays and conduit joints. Application has been made to suspend certain patents relating to meters. Two patents relating to electric furnaces expire this week after a full life of fourteen years (p. 305).

THE estimated loss on the L.C.C. tramways for 1915-16 is £91,614 (p. 306).

CONSIDERABLE difficulty is being experienced in maintaining direct wireless communication between Germany and America (p. 306).

NEW ironclad switchgear and examples of street lighting by half-watt lamps are illustrated in our Trade Section (p. 307).

A LOAN of £20,000 is to be taken up for mains at

Bradford; cable, cable accessories and transformers are required at Dublin; electrical stores at Edinburgh and generating plant at Halifax and Erith (p. 307).

THE Manchester electricity undertaking showed a satisfactory profit last year notwithstanding the war.—The municipal wiring powers recently granted to Plymouth by a House of Lords Committee have been modified by the Lord Chairman of Committees, who has substituted the old "model" clause stipulating that work shall be done through a contractor (p. 308).

AT the annual meeting of the General Electric Co. last week reference was made to the large amount of Government work which the Company was carrying on.—No interim dividend is to be paid at present on the ordinary shares of the Newcastle-on-Tyne Electric Supply Co. (p. 308).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING JULY 24TH, 1915,
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday:—6.30 and 7.30.—No. 1 Platoon, Technical Instruction and Squad Drill. No. 3 Squad, Squad Drill without arms.

No. 4 Squad, Squad Drill with arms.

Wednesday:—6.30 and 7.30.—Platoon and Company Drill.

Friday:—6.30 and 7.30.—No. 1 Platoon, Technical Instruction and Squad Drill. No. 3 Squad, Squad Drill with arms.

No. 4 Squad, Squad Drill without arms.

Orderly Sergeant:—R. W. T. Corbett.

Recruit Orderlies:—Squad 3, S. V. Spiers; Squad 4, J. Foxton.

Munition Work:—Owing to shortage of material, it has been impossible to arrange work for Saturday, July 17th.

Camp at Thames Ditton:—The Architects will welcome any member of the E.I.V.T.C. who wishes to spend the week-end in camp. Names must be given to the undersigned by Wednesday morning, and members going to camp must take with them blankets, knife, fork, spoon, cup, and soup plate: expenses about 7s. 6d.

Punctuality on Parade:—Owing to the amount of time lost on falling-in on parade, members are reminded that drills commence at 6.30 and 7.30, and every man must be in position when the fall-in is sounded. Any member who is not present when his name is called will not count a drill for the hour for which he is late.

E. G. FLEMING.

(Company Commander and Acting Adjutant.)

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W.

The Electrical Market in China.—H.M. Consul at Shanghai (says the *Board of Trade Journal*) reports that the importation of machinery and the installation of electric lighting apparatus in China is worthy of the closest study by British firms. Last year the Shanghai municipality supplied over 40 million units, compared with 21 million units in the previous twelve months, and no less than 1,500 radiators have been installed in Chinese houses. British installations have recently been completed for a number of large cities in China, but hitherto the business has been largely in the hands of Germans, mainly because they have been willing to undertake entire contracts and to finance them.

ELECTRICAL MEN ON MILITARY SERVICE

THE fourth list of members of the Institution of Electrical Engineers on military service has just been issued, and includes 228 names, bringing the total to 1,033. The first list was published in our issue of Jan. 21st, the second list on Feb. 18th, and the third list on March 4th. We give the fourth list in full below:—

MEMBERS.

R. L. Alkin (2nd Lieut.); Brig.-Gen. W. B. Brown (R.E.); J. H. Butters (Capt. Australian Engineers); L. E. Caine (Director British East African Field Telegraphs); W. S. Carr (Lieut. R.G.A.); W. L. Carter (Capt. Hong-Kong Volunteer Reserves); C. L. Cartwright (Lieut. Madras Volunteer Guards); J. K. Catterson-Smith (Lieut. R.N.V.R.); J. Clarke (Lieut. Nauru Volunteer Reserve); Major C. G. G. Crawley (R.M.); H. Dawson (Hon. Major Australian Engineer and Railway Staff Corps); G. H. J. Hooghwinkel (Capt. R.F.A.); Major J. N. C. Kennedy (R.E.); H. S. King (Sergeant New Zealand Field Engineers); Lt.-Col. E. H. Leaf (R.E.); Lt.-Col. H. M. Leaf (R.E.); G. McAlpine (Lieut. R.N.V.R.); J. M. S. Maxwell (Capt. R.E.); T. H. Minshall (Major R.E.); J. S. Pringle (2nd Lieut.); F. J. Robins (Lieut. 1st Calcutta Volunteer Rifles); W. A. Vignoles (Major).

ASSOCIATE MEMBERS.

C. E. Abell (2nd Lieut.); J. O. Archer; J. G. Balsillie (Chief Radio Censor, Melbourne); Capt. J. S. Barker (R.E.); W. F. B. Bartram (Lieut. R.M.); T. O. H. Bates (2nd Lieut. Indian Army); H. L. Bazalgette (Lieut. R.E.); R. G. Beer (2nd Lieut. R.E.); H. B. Bennett (2nd Lieut. Indian Army); P. R. Blake (A.B. Anti-Aircraft Corps); R. W. H. M. Bland (Lieut.); E. G. Boissier (Sub-Lieut. R.N.D.); F. H. Brandreth (2nd Lieut.); C. A. Brearley (Sapper Divisional Engineers, R.N.D.); A. W. Brown (2nd Lieut.); M. A. Bulloch (Lieut. A.O.C.); K. D. Bullpitt; Capt. E. D. Carden (R.E.); J. H. Cardew (2nd Lieut. R.F.A.); W. J. I. Casewell (Divisional Engineers, R.N.D.); P. J. Clears; J. Coghlan (Australian Field Engineers); Major S. H. Cowan (R.E.); F. G. Cresswell (Engr.-Lieut. R.A.N.); A. E. H. Dinham-Peren (Lieut. South African Engineer Corps); W. E. Downey (Lieut. A.O.C.); P. Dunsheath (2nd Lieut. R.E.); G. B. Dyke (2nd Lieut. R.G.A.); E. A. Edwards (2nd Lieut. R.E.); A. W. Empson (Mechanic Motor Machine Gun Service); C. T. Eriksson (Lieut. Rhodesia Reserve Volunteers); Major L. Evans (R.E.); C. L. Faunthorpe (2nd Lieut.); P. L. R. Fraser (Lieut. R.N.V.R.); Hon. E. Fulke French (Divisional Engineers, R.N.D.); M. R. Gardner (A.B. Anti-Aircraft Corps); F. J. Gellion (Hong-Kong Volunteer Reserves); J. W. Gibson (A.B. Anti-Aircraft Corps); S. C. Gibson (Lieut.-Comm. R.N.V.R.); V. W. Gill (Divisional Engineers, R.N.D.); H. Gray (Capt. R.F.A.); J. W. Griggs (Divisional Engineers, R.N.D.); W. Harling (Lieut. R.E.); E. J. Harper (Divisional Engineers, R.N.D.); R. A. Harris (2nd Lieut. R.E.); J. R. Henry (South African Burgher Commando); W. J. Henry (Sub-Lieut. R.N.D.); W. Hockley (Squad-Comm. Vancouver Engineer Reserves); F. R. Hoggett; G. A. Hollings (Bombay Volunteer Rifles); Stratton Holmes (Lieut. R.N.V.R.); W. Holmes; F. H. Horner (2nd Lieut. R.E.); B. Hoyle (R.E.); A. H. Huddart (Lieut. A.S.C.); D. G. Hurllab (Bombay Volunteer Rifles); P. S. E. Jackson (Madras Artillery Volunteers); J. G. Jones; Major G. S. Knox (R.E.); P. B. Lawson (Director of Posts and Telegraphs, Cameroons); R. F. Long (Hong-Kong Volunteers); R. T. McArthur (Capt. South African Field Telegraph Corps); C. R. McGowan (Lieut. R.E.); Capt. C. H. Malden (R.M.L.I.); T. S. L. Mann (Westminster Dragoons Yeomanry); G. E. Marley (Hong-Kong Volunteer Reserves); H. F. Mason (Lieut. R.G.A.); T. H. Matthewman (Hong-Kong Volunteer Reserves); W. J. Mitchell (Lieut. N.Z.G.A.); S. M. Mohr (2nd Lieut.); A. R. Newman (R.N.); J. O. Nichol (Lieut. R.N.V.R.); C. H. Noyce (Divisional Engineers, R.N.D.); H. Ogilvie (Canadian Force); G. Paton (2nd Lieut.); F. G. Payne (Lieut.); J. V. Payne (Driver A.S.C.); A. Podmore (2nd Lieut. R.E.); B. Pontet (Bihar Light Horse Reserve); A. R. Z. Porter (Lieut.); T. Y. Porter (2nd Lieut. A.S.C.); T. F. Potts (Staff-Sergeant, R.E.); H. H. L. Prendergast (2nd Lieut. Railway Transport Dept.); E. B. C. Preston (2nd Lieut. 32nd Sikh Pioneers); A. R. Price (2nd Lieut. Reserve of Officers, Indian Army); Capt. W. C. H. Prichard (R.E.); J. D. K. Restler (Sub-Lieut. R.N.D.); Major G. B. Roberts (R.E.); A. M. Robertson (2nd Lieut. R.E.); Comm. E. G. Robinson (R.N.); C. G. Seeley; R. C. Simpson (Lieut.-Col. Australian Militia); D. H. Slack (2nd Lieut. R.E.); Prof. C. A. M. Smith (Hong-Kong Volunteer Reserves); F. Smith (Calcutta Scottish Volunteers); T. V. Smith (2nd Lieut. Royal Flying Corps); W. H. Smith (Capt. R.E.); V. Sorby (Chief Petty Officer R.N.); R. E. Staco (Capt. R.E.); H. A. Starkey (Lieut. Calcutta Naval Volunteers); W. D. Stewart; C. Stafford (Hong-Kong Volunteer Reserves); J. H. Thomas (2nd Lieut. R.E.); F. E. Tilley (Divisional Engineers, R.N.D.); C. G. Trevett (Lieut. South African Engineer Corps); F. L. N. Tuck (2nd Lieut. New Zealand Territorial Force); A. E. Turpin (2nd Lieut. R.F.A.); G. L. Walsh (Canadian Force); W. H. Walton (A.B. Anti-Aircraft Corps); A. G. Warren (Hong-Kong Volunteer Reserves); P. D. Webb (Calcutta Scottish Volunteers); R. H. Whittington (Lieut.); H. G. Wightwick (2nd Lieut. Singapore Volunteer Infantry); A. P. Williams (Australian Field Engineers); R. A.

Williams (2nd Lieut. R.E.); A. C. Wilmot (Staff Lieut.); J. L. Wilson (Lieut. R.E.); W. Winkworth (2nd Lieut.); A. E. G. Wood (Divisional Engineers, R.N.D.); J. Young (2nd Lieut.).

ASSOCIATES.

E. K. Abbott (Natal Carabiners); A. E. Brown (Capt. New Zealand Garrison Artillery); W. Brown (Hong-Kong Volunteer Reserves); Capt. T. C. Cunningham (R.G.A.); H. Fulton (Capt. and Hon. Major R.E.); R. Griggs (R.E.); Col. W. F. Hawkins (R.E.); R. H. Kent; Major M. C. Maunsell (Reserve of Officers); Rev. F. W. R. Metcalf (Chaplain R.N.); J. E. Newman (London Electrical Engineers); W. A. Quennell (Capt. A.O.C.); A. J. Saltren-Willett (Lieut.-Col. R.G.A.).

GRADUATES.

G. J. Baldock (Australian Artillery); F. L. Cater (A.S.C.); H. Cross (Lieut. Australian Force); F. C. Davies (Bombay Volunteer Rifles); I. Day (Hong-Kong Volunteer Reserves); J. P. Feloy (Lieut. R.G.A.); G. E. F. Graham (Wireless Telegraph Officer R.A.N.); L. T. G. Mansell (Lieut. A.O.C.); G. T. Medforth (Royal Canadian Engineers); C. E. Monks (2nd Lieut.); R. E. L. Owen (2nd Lieut. R.G.A.); E. A. Richards (2nd Lieut.); C. W. Saunders (New Zealand Engineers); W. J. Shaw (Lieut. A.S.C.); E. Wyatt (Divisional Engineers, R.N.D.); V. L. Wynyard-Wright (2nd Lieut. Indian Army).

STUDENTS.

G. D. Aspland (Lieut. R.E.); H. G. Baker (Divisional Engineers, R.N.D.); E. D. Begg-Robertson; B. L. Bishop (2nd Lieut. R.E.); H. Booker (Divisional Engineers, R.N.D.); H. A. Bower (Flight Sub-Lieut. R.N.A.S.); F. Carter; R. M. Clark (Divisional Engineers, R.N.D.); C. V. Clarke (2nd Lieut.); R. St. J. (New Zealand Force); B. C. Clayton (Flight Sub-Lieut. R.N.A.S.); C. Dawnay; I. G. D. de Grandpré (French Army); F. F. Duckworth (Hong-Kong Volunteers); R. C. Dunn (New Zealand Force); C. T. Eaddy; A. R. Fiske; N. V. Foote (Australian Light Horse); G. M. Friake (2nd Lieut.); J. E. Griffiths (H.A.C.); T. H. Hall (2nd Lieut. Cape Garrison Artillery); J. B. Hartley (Air Mechanic R.N.A.S.); L. D. Hill (Sub-Lieut. R.N.V.R.); E. R. Hillman; H. Hudson (Canadian Force); P. R. Hughes (2nd Lieut. R.F.A.); F. E. Hunt; E. H. James (Australian Fortress Engineers); D. H. Linsley (2nd Lieut. R.F.A.); B. S. Lion (2nd Lieut. R.E.); R. M. McNaught (2nd Lieut. R.E.); A. P. Mackie (New Zealand Engineers); E. Marks; E. L. Morgan (2nd Lieut. R.F.A.); F. T. F. Obert (London Electrical Engineers); B. H. O'Brien (R.E.); A. C. Pallot (2nd Lieut. R.E.); S. E. T. Pryce (2nd Lieut. R.A.); A. H. Pullan (2nd Lieut.); B. S. S. Rockey (2nd Lieut. R.E.); H. G. Seagrave; H. D. Shaw (R.E.); A. Shearman (2nd Lieut. R.E.); E. Simkiss (2nd Lieut.); J. B. Snell (2nd Lieut. R.E.); V. Soper (2nd Lieut.); C. D. Stoneham (2nd Lieut. R.E.); G. O. Tipping (2nd Lieut. R.E.); H. S. Tissah (Sub-Lieut. R.N.V.R.); R. H. N. Vaudrey (2nd Lieut. R.E.); H. C. Vereker (Flight Sub-Lieut. R.N.A.S.); E. H. Vick (R.E.); H. A. Voss (London Electrical Engineers); A. E. W. Wemyss (R.E.); D. Wilkin (R.E.); J. R. A. Willey; C. S. Williams (Divisional Engineers, R.N.D.).

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE new session of the University of Liverpool begins on Tuesday, October 5th. The courses in Electrical Engineering are under Prof. E. W. Marchant, and Associate Professor A. Bromley Holmes. Prospectuses of the Faculty of Engineering may be obtained from the Registrar.

The courses in Electrical Engineering and other subjects at the Manchester Municipal School of Technology will commence as usual on October 5th. Matriculation and entrance examinations will be held in September. The school is in connection with the University of Manchester, and the principal is Mr. J. C. M. Garnett.

The annual report of the City and Guilds of London Institute states that the war had a very marked effect upon the entries of students for the session now running, and about 160 who would have returned enlisted or were called to the colours. In March of this year there were 402 students, as compared with 605 for 1913-14. Twenty-four of the teaching staff and workmen from South Kensington, and eight from Finsbury, are now serving in the Navy or Army. As far as is known 839 staff and past and present students are serving with the forces.

The programme of the City and Guilds Technical College, Finsbury, has also just been issued, and contains particulars of the courses in electrical and other branches of engineering, which will be held next session as usual. The electrical work is under Prof. Silvanus P. Thompson, and there are extensive facilities for laboratory work.

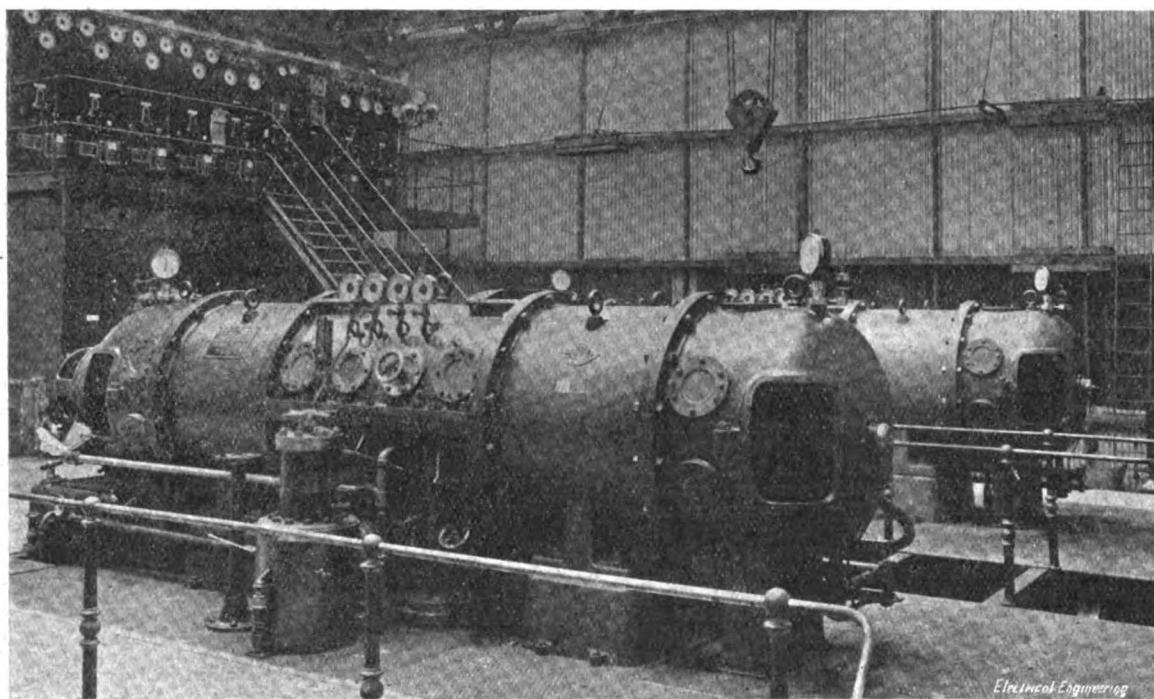

The following awards have been made in the Faculty of Engineering at University College:—Archibald P. Head Medal and Prize: B. C. Drummond. Studentship in Heating and Ventilating Engineering: G. F. Mitchell. Engineering Diplomas:—P. W. Baker (Mechanical); E. E. Barnard (Civil and Municipal); J. R. D. Bushell (Civil and Municipal); P. L. Capper (Civil and Municipal—with distinction); H. N. Charles (Mechanical); T. C. Chua (Civil and Municipal); B. C. Drummond (Mechanical—with distinction); H. Foad (Civil and Municipal); G. K. Pillai (Civil and Municipal); and S. L. Wong (Civil and Municipal).

1,000 K.W. LJUNGSTROM TURBO GENERATORS AT LUTON

WE have had the opportunity, through the kindness of Mr. W. H. Cooke (Borough Electrical Engineer, Luton), of inspecting the pair of 1,000-kw. Ljungström turbo-alternators, which have been at work in the Luton Electricity Works since last February. These sets were made by the Brush Electrical Engineering Co., and are generally similar to the set running at the St. Pancras Electricity Works, which was described in ELECTRICAL ENGINEERING, October 29th, 1914, page 561, and in this case also each consists of one turbine driving a pair of alternators in opposite directions, so that a very high relative speed is obtained between the two interleaved systems of blading attached to the shafts of the two machines. Each set is rated at 1,000 kw. at 6,600 volts three-phase 50 cycles, and the excellent steam consumption obtainable with this system is shown by the following guaranteed figures, which there is every expectation will be reached or even improved upon when the official tests come to be made:—Full load, 12·3 lb., and half load 13·7 lb. per kw.-hour. These figures are based on a power factor of 0·8 and 150 lb. per sq. in. steam pressure, with a total steam

gradually widening blading, leaving through a diffuser of multi-cellular construction and similarly widening channels and passing into the surrounding exhaust space. Labyrinth packing is provided at the shafts and between the revolving discs and the side discs, and the constructional details are of remarkable ingenuity, especially as regards the building up to the cages of blades, and their flexible attachment at alternate ends to the revolving discs. The most complete precautions have been adopted to avoid distortion from temperature effects. Summing up the general features, it may be said that the great economy obtained is due to the high relative blade speed, the small internal leakage, and the care taken to minimise radiation and other losses.

The blading rings are quite easy to remove and replace, and their construction renders them extremely strong. The provision for expansion is such that steam may be turned on rapidly without any gradual warming-up, and the presence of water does not apparently harm them. The sets run with so little vibration that a two-shilling piece can remain balanced on its edge on the casing when running at full load. The governing is entirely by throttle, with emergency trips actuated by hand, by rise of temperature of any bearing or by an independent overfeed device. The main governing is partly effected by the same oil pressure that feeds the

Electrical Engineering

1,000-KW. LJUNGSTROM TURBO-ALTERNATORS AT LUTON ELECTRICITY WORKS.

temperature of 700° F. and a 28-in. vacuum (barometer 30 in.).

Powers were obtained for the extensions in which these machines figure about two years ago, but delays in building operations were principally responsible for their not having been at work sooner. At the present time, they are practically fully loaded, and another 3,000-kw. set. A view of one of the complete sets, showing their remarkable compactness, is shown in the figure.

It will be remembered that the Ljungström turbine is in principle a reaction machine, although differing in construction radically from any other design. Briefly, it is a radial-flow turbine, in which the steam is admitted between two discs, and in its passage it passes between concentric blading rings, carried alternately by the two discs. The two discs revolve in opposite directions, and to the shaft of each is attached a generator. Notwithstanding the fact that two generators are employed, however, the complete set is extraordinarily compact for its output. There is no blading carried on split cast-iron casings, for it is all mounted on the concentric rings. This construction avoids risk of distortion when high superheats are adopted. The turbine is supported principally on the lower part of its casing, forming its exhaust branch, and can be mounted direct on the condenser without requiring separate foundations. The steam is led in by pipes within the lower part of the casing to chambers on either side of the discs, whence it passes through holes in them to the central annular space within the discs. It then passes radially through the

bearings. The weight of the set is mainly supported on the exhaust flange connected to the condensing plant below, the two feet under the generators being supported on springs. The condensing plant has no very unusual features; the pumps are all driven by D.C. motors, and can be supplied by the station battery in emergency. A Sturtevant wet-air filter is used in connection with the ventilation of the alternators.

The sets are placed in an extension of the main engine room built for the purpose, and containing a new switchboard by Johnson & Phillips, Ltd., with the necessary machine panels and several new feeder panels. The voltage is regulated by a pair of Brown-Boveri automatic regulators, one from each set. These act on the field circuits of the direct-coupled exciters with which each set is provided. Two new Woodeson water-tube boilers, each of an evaporative capacity of 30,000 lb. per hour, with underfeed stokers, have been provided in an extension to the boiler-room, which is of sufficient size to accommodate six more of the same size. Overhead bunkers of a capacity of 1,800 tons are provided. It is interesting to note that tests of this new boiler plant have shown an average of 0·15 lb. of coal per unit sold on actual load, whereas the corresponding figure to the old boiler plant was 0·38 lb. A new chimney shaft has been built for these boilers, and the extensions have also necessitated additions to the cooling tower equipment.

THE OSRAM v. POPE PATENT ACTION

THE hearing of this action was completed before Mr. Justice Joyce on Tuesday, and judgment has been reserved.

Mr. Ballantyne continued his evidence on Wednesday last week on behalf of the Pope Co., and denied that there was any moisture present at any stage in his experiments. Witness was cross-examined at considerable length by Mr. Walter, K.C., for the Osram Lamp Works, Ltd., the main result of which was that he differed from the chemical witnesses on the other side as to the chemical reactions which take place in working the Just and Hanaman patent.

Evidence in support of Mr. Ballantyne's views were given by Prof. F. G. Donnan, F.R.S., Professor of Physical and Inorganic Chemistry, University College, London; Mr. F. J. Gill, one time assistant to the late Mr. Robertson, of the Robertson Lamp Works, Hammersmith; and Mr. A. H. Rose. The latter stated that he had attempted to follow out the Just and Hanaman process, but failed to make what he termed a commercial filament. During the cross-examination of these witnesses it was suggested that the late Mr. Robertson at Hammersmith had been experimenting with the Just and Hanaman process at the time the first filaments were imported from Germany, and that he had failed to make satisfactory filaments in that way. At the close of the case for the defendants Mr. A. J. Walter, K.C., obtained leave to call Mr. C. Wilson, Commercial Manager of the Osram Lamp Works, Ltd., to explain the reasons why the late Mr. Robertson had been unable to make filaments according to the specification, but as it was elicited that Mr. Wilson only knew of the cause of the failure through conversations with the late Mr. Robertson, the judge held that this could not be admitted as first-hand evidence, and Mr. Terrell, K.C., for the defendants, objecting, the evidence was not admitted.

In making his final speech for the defendants, Mr. Terrell said that he would not go into the chemical details for discussing the various chemical reactions which took place in the process. His case, he maintained, was perfectly plain on the language of the specification as it had been drawn, and to attempt to go into all the remote reactions which took place in order to try to establish which reactions take place in such minute quantities was to him a hopeless task. Mr. Justice Joyce remarked that he did not think the case turned on this. Mr. Terrell then summed up the evidence in relation to the points already made for the plaintiffs by Mr. Hughes, K.C. (ELECTRICAL ENGINEERING, July 8th, p. 294).

Mr. A. J. Walter, summing up on behalf of the Osram Lamp Works, Ltd., contended on the question of infringement that the wording of the patent specification as to the heating of the filaments taking place in an atmosphere of steam and hydrogen did not imply that the steam and hydrogen was applied as a mixture to the filaments irrespective of anything taking place in the filaments. A discussion took place between the judge and Mr. Walter as to whether what was given off during the course of the defendants' process, and which was claimed by the plaintiffs to be steam, was in reality steam. Mr. Walter contended that it was steam inasmuch as true steam was invisible. Mr. Justice Joyce, however, said that they might have to read the specification in the popular sense that steam was a visible substance. On the other hand, Mr. Walter urged strongly that steam as popularly known was not steam, but a cloud of condensed water, and that in consequence any steam as known scientifically given off during the course of the defendants' process must bring it within the scope of the specification. Continuing, Mr. Walter said it was perfectly well known that passing dry hydrogen over oxide of tungsten produced steam, and that was why the defendants used oxide of tungsten. But for that there was no object in using oxide of tungsten. If nitrogen had been used instead of hydrogen, there would not have been infringement, because no steam would have been formed. Mr. Justice Joyce pointed out that the specification said that an atmosphere of steam and hydrogen was "introduced," but Mr. Walter replied that his reading of the specification was that this merely meant that an atmosphere of steam and hydrogen was present. The judge, however, did not agree.

In the course of further remarks, Mr. Walter dealt with the question of infringement, and the subject-matter in relation to the validity of the Just and Hanaman patent, and cited a number of well-known cases to prove that a patent could not be held to be invalid because it took a known process and applied it to a totally different metal. This was assuming that it was the Just and Hanaman process that had already been applied by Welsbach to osmium. He argued, however, that Just and Hanaman had produced an entirely new thing, and that before their patent and without it a tungsten filament lamp could not be made.

The Rugby Engineering Society.—The proceedings of this Society for the session 1913-14 contains among other items the following Papers, with reports of discussions thereon: "Some Recent Improvements in Power-Driven Forging and Stamping Plant," by W. Spencer; "The Electrical Design of Induction Motors," by H. L. Smith; "Electrical Accessories for Automobiles," by H. Procter; and "Power Economics for Intermittent Loads," by E. J. David.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS : We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS : A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,551.

A motor-generator for electroplating work is required to run off a 3-phase supply, and is to give out a current of about 8,000 amperes at a voltage variable between 4 and 8. Is it possible to obtain such a variation by the ordinary method of shunt regulation if the machine is self-excited, or is it better or necessary to arrange the fields for separate excitation? Could the variation in volts be satisfactorily accomplished by regulation on the motor side? What are the advantages or disadvantages of using carbon brushes as against copper gauze brushes on a generator of this size?

"W. M."

(Replies must be received not later than first post, Thursday, July 22nd.)

ANSWERS TO No. 1,449.

No reply of sufficient merit for an award has been received.

ANSWERS TO CORRESPONDENTS

J. M.—Overhead tramway feeders are used in a number of cases where the Board of Trade has no objection.

ALPHA.—The voltage between phases and earth of a 6,600-volt

3-phase system with the neutral earthed will be $\sqrt{3}$ = 3,800 volts.

With the neutral insulated or with a delta connected system it would theoretically be the same if the insulation resistance and capacity of all the phases are the same, actually it can be anything from this value to the extreme case of a dead earth on one phase when the other two will be at the full 6,600 above earth.

Diesel Engines.—In the course of a lecture to the Junior Institution of Engineers, Mr. W. A. Tookey referred to the many excellencies of design apparent in the Diesel engine constructed by British engineers, and called attention to various details of the operating mechanism. He also referred to the high rates of premium asked by insurance companies against breakdowns of Diesel engines. These, he thought, proceeded mainly from the over-stressing of cranks, and excessive heating of pistons, due to over-rating the permissible output from given cylinder dimensions. He was inclined to lay the blame not upon the technical men responsible for the details of construction, but upon those entrusted with the negotiations with prospective purchasers, who were particularly interested in being able to claim as small a ratio as possible in the relation between horse-power developed and capital cost. The lecturer proceeded to discuss the question of rating and the effect of the continuance of high mean effective pressures upon the piston, &c., consequent upon the use of rich mixtures coincident with full load and over-load. He then explained the manner in which the regulation of the fuel supply by the governing mechanism was effected and why it was necessary to vary the blast pressure with the load. He referred also to the regulation of the blast with different classes of liquid fuel, and mentioned a figure which it was inadvisable to exceed for mean effective pressure as a working load. He next dealt with the vexed question of over-load capacity, and concluded with references to the manipulation of details in starting, running, and stopping. Particular emphasis was laid upon the paramount importance of scrupulous cleanliness, which depended quite as much upon the personal attributes of the attendant as upon his technical ability.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 8th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

19,445/13. High Frequency Alternators. M. BRESLAUER. A high frequency alternator with the armature windings of full pole pitch arranged in the armature so that the centre line at right-angles to their plane is staggered in relation to centre line of the salient poles of the armature by half a pole pitch for the purpose of multiplying the number of alternations of the current without simultaneously increasing the number of reversals in the magnetisation of the iron. (Eleven figures.)

7,007/14. Voltage Regulators. B.T.-H. Co. (*A.E.G.*). An improved form of quick-acting voltage regulator arranged so that when the voltage variation is more than can be corrected by acting on the exciter field, a rheostat in the main exciter circuit is brought into action automatically by a voltage relay or otherwise. (One figure.)

7,200/14. Telephone Relay. C. STILLE. A microphone relay with two movably suspended coils rotatable opposite each other in a strong magnetic field, each coil carrying a number of arms, which bear against the contacts of a fixed microphone box. (Four figures.)

7,202/14. Transmission of Sound. C. STILLE. The sound waves impinge upon an arc in shunt with the primary of a transformer, the secondary of which is connected to a telephone receiver. (One figure.)

14,163/14. Conduit Joints. F. J. WINEBERG and E. T. PARKER. A continuity grip joint consisting of a sleeve formed of a single helical spring of substantial wire fitting tightly over the tube and clearing off the enamel while being forced on. (Two figures.)

19,908/14. Conduit Fittings. J. R. A. HEMMING and A. E. BECK. The combination with the socket of a conduit fitting furnished with a transverse hole and a screw pin, having at one side a recess to suit the side of the tube serrated, so that when the nut is tightened up the enamel is removed from the tube to make metallic contact. (Twelve figures.)

21,782/14. Engine Starter. A. H. MIDGLEY and C. A. VANDERVELL. An electrical engine starter for motor-cars of the class having an axially displaced armature, which draws the gear into mesh, provided with a friction disc arranged to come into engagement with the fly-wheel to start it moving before the gear is engaged. (One figure.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Dynamos, Motors, and Transformers: A.E.G. [Protection of generators from fire in air filters] 24,450/13; SIEMENS-SCHUCKERTWERKE GES. [Synchronising rotary and cascade converters] 7,684/14; SIEMENS BROS. DYN. WKS., BRAMLEY and WISDOM [Commutators] 7,779/14; SIEMENS SCHUCKERTWERKE GES. [Diminishing flywheel windage] 7,868/14; ROSENBERG [Rotary converters provided with boosters] 8,385/14; PARSONS [Dynamos] 15,585/14; SIEMENS BROS. DYN. WKS. and KIEFFER [Cooling dynamos] 16,590/14; BURDON (Siemens Schuckertwerke Ges.) [Slot closing devices] 23,868/14.

Electrometallurgy and Electrochemistry: HIGHFIELD [Reduction of ores] 6,865 and 6,866/14; MASCHINENFABRIK SURTH GES. [Electrolytic apparatus] 8,367/14.

Heating and Cooking: FRANK [Radiators] 16,680/14.

Ignition: BURDON (*Siemens & Halske A.G.*) [Ignition apparatus] 23,791/14.

Incandescent Lamps: GLADITZ [Incandescent lamps] 24,029/13; B.T.-H. Co. (*A.E.G.*) [Incandescent lamps] 7,682/14; DANFORD and BRADLEY [Candle lamps] 14,669/14; SIEMENS BROS. & CO. and LE MARÉCHAL [Metal filament lamps] 15,329/14; JONES [Electric lamps and holders] 15,489/14; SABINE [Wire filaments] 15,617/14; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Incandescent lamps] 21,435/14.

Instruments and Meters: SIEMENS BROS. & CO. and GRINSTED [Fault indicator] 8,473/14; B.T.-H. Co. (*G.E. Co., U.S.A.*)

[Motor meters] 15,194/14; LINCOLN [A.G. Measuring instruments] 22,487/14.

Storage Batteries: NYA ACKUMULATOR AKTIEBOLAGET JUNGNER, A. T. H. ESTELLE and K. N. W. EVERE [Iron-cadmium battery electrodes] 7,338/09.

Switchgear, Fuses and Fittings: DAUM [Fuses] 15,749/14.

Telephony and Telegraphy: WITHERS (*Cox*) [Selenium cells for use in connection with telephony] 12,361/14; ROBERTS [Wireless receiver] 19,054/14; BLOGG and STERLING [TELEPHONE & ELECTRIC CO. [Intercommunication telephones] 21,955/14.

Traction: MCREYNOLDS [Trolley wheels] 7,214/14; BROWN, BOVERI & CIE. [Regenerative braking] 7,265/14; HOBHOUSE, SLINGO, GUNTON, and DOUGLAS [Railway system for mails] 14,984/14.

Miscellaneous: BECKMANN [Speed indicators] 3,020 and 3,021/14; GRISSEON [Cooling of Rontgen-ray tubes] 8,147/14; SCHMIDT & DOBSLAW [Pocket lamps] 8,353/14; MARTIN [Electric signs] 14,800/14; BRITISH INSULATED & HELSBY CABLES, LTD., BAXLES and HIGHAM [Condensers] 14,817/14; PEARSON [Lamp-holder with contacts for portable lamps] 18,870/14; BRUCK [Magnetic separators] 20,552/14; SAINT [Mercury contact for mining signal indicators, &c.] 1,453/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Ignition: POGNON [Sparkling plugs] 8,367/15; JOLY [Sparkling plugs] 8,717/15.

Miscellaneous: R. BOSCH [Lanterns] 5,866/15; VARLEY [Systems of producing electrical discharges] 9,111/15.

Applications to Avoid or Suspend Patents

Meters. 21,027/03, W. HAMILTON; 26,359/12 and 12,926/14, W. HAMILTON and FERRANTI, LTD. Applications regarding these patents by Ferranti, Ltd., will be heard by the Comptroller on July 15th. The first is for the general construction of a form of mercury motor meter, the second relates to details of the mercury trough, and the third is for improvements to facilitate removal of the disc.

Application for Amendment

9,582/14. Electric Railways. K. E. STUART. Leave is sought to correct a clerical error in this specification, which describes a system of driverless railways for the conveyance of mails, &c.

Opposition to Grant of Patents

28,527/13. Control Gear. R. AMBERTON. A grant has been allowed on this application, in spite of opposition. The specification describes a motor starter, in which the rheostat is electrically interlocked with electromagnetic circuit breakers.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:-

14,486/01 and 14,643/01. Electric Furnaces. J. IMRAY (*Société Electro-métallurgique Française*). The first of these describes an electric furnace for the production of wrought iron or steel, in which the metal bath is protected from contact with the electrodes and the slag, &c., is discharged at a level above the metal bath. In the second a form of furnace for such purposes which can be oscillated or tilted.

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, Motors, and Transformers: CROMPTON & CO., J. C. MACFARLANE, and H. BURGE [Field magnets for converters] 7,060/09.

Electrometallurgy and Electrochemistry: J. HAWTHORNE [Electrolytic cleaning of metals] 22,625/07; F. PLATHNER [Electrolytic coating of metals] 92/08.

Telephony and Telegraphy: G. W. PICKARD [Oscillation detector] 10,772/09.

Traction: P. A. NEWTON (*Bliss Electric Car Lighting Co., U.S.A.*) [Train lighting] 6,854 and 6,855/02; H. LEITNER [Train lighting] 6,690/06.

Miscellaneous: F. STEINERT and H. STEIN [Magnetic separators] 6,323/08 and 6,267/09; W. LÖWENDAHL [Contacts] 6,412/08.

ELECTRIC TRACTION NOTES

As the result of arbitration, the employees in the electrical section of the L.C.C. Tramways Department earning up to 40s. per week are to receive a war bonus of 3s. per week. Some time ago this was granted voluntarily by the Council to men earning 30s. a week or less. The employees at the Greenwich power station applied for a general increase of 7s. per week, whilst the employees at the sub-stations made varying requests for increased rates of pay.

The estimated financial result of the L.C.C. Tramways for 1915-16 is a net deficiency of £91,614. The loss on the past year's working was £33,000, and the recent strike was responsible for a reduction in revenue of something like £100,000. The deficiency last year is to be met from the general reserve, but in view of the special circumstances arising out of the war and the strike, the Highways Committee has under consideration the possibility of arriving at some scheme for keeping the undertaking off the rates.

The draft agreement for the purchase by the Plymouth Corporation of the Devonport & District Tramways Company's undertaking has now been prepared.

In the last annual report of the Burnley Tramways Department it was stated that iron axles were being experimented with. Long experience, however, has shown that their life is, after all, too short, and the use of steel axles has been reverted to.

The Dover Corporation is arranging a contract with Edison Accumulators for the supply of six electric vehicles for departmental purposes. A first payment of £1,690 has been made.

The Annual Congress of the Tramways & Light Railways Association will be held at the Institution of Civil Engineers, Great George Street, Westminster, to-morrow (Friday). The following papers will be read and discussed: "Glimpses into the Obvious," a Paper on tramway management, by A. V. Mason, General Manager and Engineer, South Metropolitan Electric Tramways & Lighting Co.; "Tramways during War Time," by J. W. Dugdale, General Manager, Oldham Corporation Tramways; and "Electric Battery Vehicles as Adjuncts to Tramways," by W. H. L. Watson.

In connection with the annual written technical examination of commercial motor vehicle drivers, which was held

as usual this year by the Commercial Motor Users' Association, in spite of the Whit Monday parade being abandoned, a special electric-car drivers' prize of £5 with certificate has been awarded to J. Grove, employed by E. Nelson & Co.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

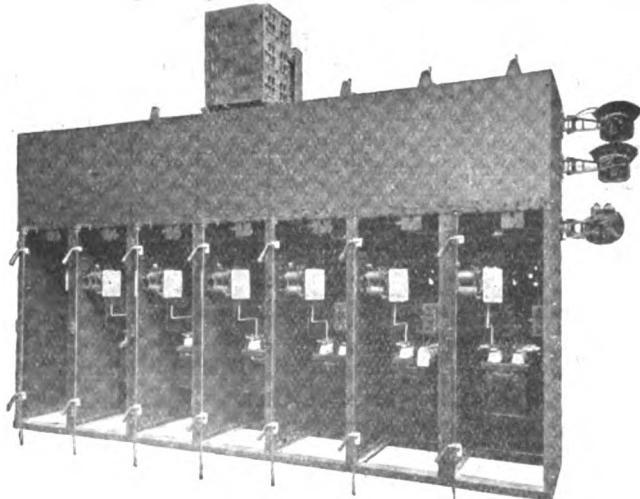

The *Electrical World* (New York) announces that the Nauen-Sayville and Hanover-Tuckerton transatlantic wireless systems, which have lately been transmitting the bulk of telegraphy traffic between the United States and Germany, have for the past two weeks suffered severe service interruptions. Although the plants have been found to be sufficiently powerful to interchange messages, even by daylight, during the winter season, with the coming of warmer weather (and the accompanying increase of "static") communication has become impossible for a large part of each day, and it is believed that commercial radio-telegraphy between the United States and Germany will not again be possible until autumn. At the present time the German War Office reports are transmitted through England. The Sayville transmitter is being enlarged so as to improve sending to Germany, but this will, of course, not aid reception in the United States. Many combinations of receiving apparatus are being tried both at Tuckerton and Sayville, in the hope of eliminating "static" interference to such a degree as to permit the German signals to be read.

A correspondent writes us as follows:—"Can you furnish me with any data regarding the influence of minerals in the earth upon wireless messages passing above them? I believe experiments made from balloons have demonstrated that the interference from the mineral deposits below extended above the altitude of the balloons. I am making some experiments in electrical mineral indication. How can I detect or measure the reflected waves which have rebounded from the obstruction of mineral in the ground, whose effect is added to that of the original waves?" Perhaps some of our readers can give the assistance asked for.

"ELECTRICAL ENGINEERING" TRADE SECTION

"WITTON" IRONCLAD HIGH PRESSURE SWITCHGEAR

AT the present time many manufacturers are finding it necessary to lay down plant for special purposes, and in

BACK VIEW OF "WITTON" BOILER PLATE MISTAKE-PROOF MAIN SWITCHBOARD.

such cases the benefits of electric driving are being very widely appreciated. In this connection totally-enclosed iron-

clad switchgear has many advantages, among which are that it occupies a small amount of room, requires no special foundations, can be rapidly erected, and makes a thoroughly permanent job. A representative example of a mistake-proof ironclad switchboard, as manufactured by the General Electric Co., Ltd. (Witton, and 67 Queen Victoria Street, E.C.) is shown in the accompanying illustration. This switchboard was constructed for a large steel works. It was built up of a number of "Witton" mistake-proof switch panels, each self-contained, and on arrival at the works the only erection work necessary was the connecting together of the different panels and the connecting up of the cables. This switchboard, which is one of a large number for similar orders now passing through the Witton works, was constructed to control, amongst other plant, a 750-kw. motor-generator manufactured by the General Electric Co., Ltd., to convert three-phase power at 3,300 volts, 50 cycles, to continuous current at 550 volts on the three-wire system, a static balancer being part of the equipment.

The "Beama" Journal.—The third issue of the official journal of the British Electrical and Allied Manufacturers' Association contains, among other contributions, articles on the electric industry in China and in Johannesburg. The needs of the industrial situation are also reviewed by Mr. J. Haworth, and Mr. L. Gaster has something to say on the progress of illuminating engineering. The only technical article is one by Mr. N. Shuttleworth on a method of speed regulation of induction motors. Several firms contribute illustrated notes on their activities and on novelties mostly already familiar to readers of our columns, and a large number of pages are filled by advertisements of members of the Association.

RAILWAY STATION LIGHTING BY OSRAM "ATMOS" LAMPS

A GOOD example of the use of gas-filled tungsten lamps for railway station lighting is presented by the Caledonian Railway Co.'s station at Glasgow. This station was originally lighted by 10-ampere open-type arc lamps with opalescent globes, running four in series on 230 volts, the total number of arcs employed being approximately 120. Inside the main entrance, containing the booking hall, offices, bookstalls, and waiting-rooms, the lamps were mounted

FIG. 1.—CENTRAL STATION, GLASGOW (CALEDONIAN RAILWAY), SHOWING SOME OF THE PLATFORMS ILLUMINATED BY OSRAM ATMOS TYPE LAMPS.

at a height of about 22 ft., and were spaced from 60 to 80 ft. apart. Along the platforms they were mounted at the same height, the average spacing being 80 ft. These arc lamps have now been replaced by 500-watt Osram Atmos type lamps. These occupy the positions previously occupied by the arc lamps. The result has been that there is a reduction of 300 watts on each circuit of four lamps, while at the same time the illumination of the station has been increased and

FIG. 2.—CENTRAL STATION, GLASGOW, BY DAYLIGHT, SHOWING DISPOSITION OF THE LAMPS.

considerably improved by the more even illumination obtained from the new lamps. Moreover, they require less attention. The horizontal illumination in the main hall of concourse is 2 ft.-candles maximum, with a minimum of 1'7 ft.-candles, while along the platforms the variation is between 0'8 and 1'6 ft.-candles. The photograph reproduced in Fig. 1 gives an idea of the brilliant effect obtained; and a general view by daylight, showing the old arc lamp carcasses, now containing the Osram Atmos type lamps, is given in Fig. 2.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Bradford.—An application is to be made to the L.G.B. for a loan of £20,000 for mains, &c., required for extensions in connection with war requirements.

Chesterfield.—A short time ago the L.G.B. declined to sanction a loan of £5,000 for new plant, but the matter has been pursued by the Corporation, and there is now a probability of the loan or some portion of it being allowed.

Dublin.—Supplies of cable and cable accessories, also transformers. City Electrical Engineer. July 26th. (See advertisement on another page.)

Edinburgh.—Tenders are invited for three, six, or nine

months' supply of electrical stores for the generating station. City Electrical Engineer. July 17th.

Erith.—A scheme for extending the electricity undertaking has, according to a local paper, been approved after discussion in private.

Halifax.—A loan of £24,000 is to be applied for in connection with new plant at the power station for war requirements.

London.—The linking-up scheme between the Battersea, Fulham, and Hammersmith generating stations is estimated to cost £24,989.

Sheffield.—In order to cope with the demands from factories working on Government contracts, it is necessary to instal new plant to the value of £10,500.

Wiring

Portsmouth.—Wiring and fitting of Wimborne Road school. G. C. Vernon-Inkpen, 40 Commercial Road. July 19th.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Huddersfield.—Military hospital (£15,000).

Manchester.—Co-operative Stores, Openshaw. Mr. A. H.

Walsingham.—Factory, Derby Street. Architect, C. Swain.

Swansea.—Isolation hospital (£40,000).

Miscellaneous

Bradford.—A sum of £15,000 is to be spent on renewal of the tramway track.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

London.—The Great Northern Railway Co. has placed an order with the General Electric Co. for a twelve months' supply of Osram drawn wire lamps and Osram "Atmos" type lamps.

Market Drayton.—The Council has decided to accept a tender by the Electric Lighting Co. for street lighting.

The British Thomson-Houston Co. has received an order through G. & S. Massey, of Manchester, for 98 special Fabroil pinions for power hammers for the French Government to be used in a French munition works.

APPOINTMENTS AND PERSONAL NOTES

Mr. J. W. Spark, Electrical Engineer and Manager of the Devonport electrical undertaking of the Plymouth Corporation, has been appointed, on the recommendation of Sir John Snell, to the post of Chief Electrical Engineer at West Hartlepool. The commencing salary is £400 per annum, and there were 92 applicants for the appointment.

Mr. A. R. Courtenay (late Acting Manager of the Publication Department of the General Electric Co.) was gazetted on May 20th Sub-Lieutenant in the Royal Naval Air Service, armoured Car Aeroplane Support (Royal Naval Volunteer Reserve), and is now undergoing a course of gunnery.

Mr. Spencer Hawes has been appointed Managing Director of the Reading Electric Supply Co., Ltd. Mr. E. Rowley Hill retired from the post of Engineer and Manager at the end of June last.

Mr. A. G. Ellis (of Brown, Boveri & Co., Switzerland) was married on June 7th last at Hythe to Miss E. H. Price.

Mr. C. H. Thorpe, Engineer-in-Charge at the Hammersmith electricity works, has resigned.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £93 to £94 (last week the same).

Advance in Prices.—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.) have had to advance the prices in the M. (instruments) section of their catalogue by 20 per cent. with the exception of meggers and time-switches. The prices of ammeters are cancelled, and quotations can be given on application. The prices of recording and indicating wattmeters (Pamphlet M. 1,711) are advanced 10 per cent.

Sanitas Electrical Co.—It is stated that all the directors of the Sanitas Electrical Co., Ltd., being resident in Berlin it is impossible to hold an annual meeting this year. As a matter of fact, the Company's business was suspended on August 17th last year, the Secretary has resigned, and there is not anybody to represent the Company except the solicitor, who has explained the position to the Registrar of Joint Stock Companies. The *Financial News* drew attention to the above in a recent issue.

Liquidations.—The Electrical Power Storage Co. has gone into voluntary liquidation in connection with the reconstruction of the Company following the amalgamation with Pritchett & Gold. The new Company is known as Pritchett & Gold and Electrical Power Storage Co., Ltd.—A meeting of creditors of Venners' Electrical Cooking and Heating Appliances, Ltd., will be held on July 22nd at 12.30 p.m. at Blomfield House, London Wall, E.C.

LOCAL NOTES

Aberdeen: War Loan.—It has been decided to invest £5,000 from the reserve fund into the new War Loan.

Edinburgh: Electric Supply Deficit.—The Lighting Committee recommend that the deficit last year of £6,200 be paid out of the reserve fund, and that the charge for private lighting should be increased by ½d. per unit, that for power remaining as at present, viz., 1½d. per unit. It should be pointed out that the policy of the Edinburgh Corporation has been to so fix their charges from year to year that in normal times the expenditure and receipts practically balance, after full provision for reserve and depreciation. Obviously the war was bound to affect the estimates prepared last year.

Maidstone: Loan Granted.—The L.G.B. has sanctioned a loan of £4,800 for new plant. The Corporation had entered into a provisional contract with the Brush Electrical Engineering Co. for a Ljungstrom turbine, and the amount now sanctioned is the cost of the plant, less £2,150 received from the sale of three small generating sets, and £500 to be paid out of revenue.

Manchester: Electricity Accounts.—There was a net profit of £34,926 upon the working of the electricity undertaking last year, after meeting capital charges and transferring £25,618 to renewals suspense account. This net profit compares with £36,000 in the previous twelve months. A sum of £30,000 has been transferred to relief of rates, and the balance has been absorbed in capital outlays, for which no borrowing powers exist. It is noted in the Committee's report that apart from checking the normal development of the Department, the war has had the effect of reducing the surplus by reason of war service allowances, amounting to £6,015, and additional income tax of £3,283. At the Stuart Street power station Messrs. James Howden have completed the installation of a 15,000 kw. turbo-alternator, but owing to unavoidable delays the official trials have not been made. A contract has been placed with the British Westinghouse Co. for a 6,000 kw. turbo-alternator, which will replace an existing Yates & Thom-A.E.G. reciprocating engine set. At the Dickinson Street power-house Messrs. Bruce Peebles have now completed the installation of an additional 2,200 kw. motor-converter. A supply of current at 11,000 volts to the Middleton Corporation has been commenced. The efficiency of the system was 85·87 per cent., and the units unaccounted for 14·13 per cent., the latter being a decrease of 1·38 per cent. on the previous year.

Oldham: Municipal Wiring.—A short time ago we referred to a scheme of the Education Committee for lighting one of the schools which had been placed in the hands of the Electricity Committee at a cost of £200. This led to a dis-

cussion at the Council meeting last week, when an unsuccessful effort was made to have the matter referred back. The opinion was expressed on the one hand that the work of the Electricity Department was to provide and distribute current, and not to carry out installations, but on the other hand it was urged that there was nothing harmful or unfair in one Committee doing work for another. The proposal was eventually carried.

Plymouth: Municipal Wiring.—On page 206 of our issue for May 18th we referred to the position with regard to municipal wiring in the new borough of Plymouth in reporting the proceedings before a House of Lords Committee. The old Devonport Corporation had full municipal wiring powers, and it was asked that these should be extended to the new borough of Plymouth, which included Plymouth and Devonport. There was some opposition by the Plymouth Mercantile Association, and Mr. Leonard Tate, Secretary of the Electrical Contractors' Association, was in attendance. In the end, however, the Committee granted the new borough of Plymouth full wiring powers without the intervention of the contractor. It was anticipated that there would have been considerable opposition when the Bill came before the House of Commons, but this was not so, and the Local Legislation Committee last week passed the clauses as sanctioned by the House of Lords.

Sunderland: Electricity Accounts.—The total output for the year to March 31st, 1915, was 14,499,124 units, which is a decrease of 2½ per cent. on the previous year. The power output has practically remained constant, being nearly 0·075 per cent. below that of the previous year, and moreover the demand continues, five new sub-stations having been completed. After meeting capital charges there is a balance of £4,653.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

General Electric Co.—At the annual meeting last week the report and accounts given in our July 8th issue were adopted. Mr. H. Hirst, who was in the chair, referred to the effect of the war upon the company's business, and to the fact that in the early days factors and the trade, fearing a shortage of supplies, decided to fill up their stocks and indulged in over-buying; consequently the company's stock had been considerably reduced, and had not yet been sufficiently replenished owing to reduction of output, shortage of labour, and lack of raw materials. In referring to the "well meant but ill-conceived" Press attacks on the Osram Lamp Works, Ltd., owing to the prevalence in that company of German capital, Mr. Hirst said that the Press did not sufficiently distinguish between German-owned trading concerns and factories in this country, which were useful and essential to national purposes. The importance of the Hammersmith Works, not only to the company but also to the Government and the country, was very great, and it was therefore gratifying to announce that a way had been found, with the knowledge of the Treasury and the Public Trustee, which would give the future control of these works, he trusted for ever, into British hands. About one thousand of the company's staff are now serving with the forces, of which eleven have already lost their lives, and fifty are invalided, wounded, or missing. In this connection reference was made to the unfortunate death of Mr. Harry Byng at the front, and to the fact that the company is keeping open the positions of those who have enlisted, and has made arrangements for allowances to their dependants. Dealing with the work now being carried on for the Government, it was mentioned that this includes the supply of searchlight carbons, signalling and wireless apparatus, incandescent lamps, both carbon and metal filament, power, lighting and ventilating plant for H.M. Dockyards and battleships, motors, dynamos, and every kind of electrical equipment for the Army Service Corps, hospitals and munition works, &c., field telephones and batteries, targets, exploders and shells for both services. A start has been made in the manufacture of certain types of shells, and arrangements are in progress by which the company will make itself thoroughly efficient in this department. In order to cope with the increased work created by the growth of the business, it was found necessary to add to the number of directors, and three members of the staff were selected, viz., Mr. J. Y. Fletcher, Manager of the Osram lamp business; Mr. S. D. White, who is in charge of all Government work carried on by the company; and the late Mr. George Maurice. Unfortunately, however, as our readers are aware, Mr. Maurice lost his life when the *Lusitania* was sunk by a submarine. The company has invested £200,000 in the War Loan.

Newcastle-on-Tyne Electric Supply Co.—An interim dividend of 2½ per cent. is declared on the preference shares, but an interim dividend on the ordinary shares has been postponed owing to the uncertainty of the present situation.

SUMMARY

THE annual report of the National Physical Laboratory records a considerable diminution of the staff due to the war, and a certain amount of rearrangement of the work. A good deal of Government work is being carried out (p. 310).

WE give the names of the Central Committee of the Inventions Board, which has been appointed to assist the Admiralty, and also a list of consultants who will advise on any matters referred to them (p. 310).

SOME notes are given on the forthcoming sessions, &c., of some of the Universities and Technical Colleges (p. 310).

THE Government Bill limiting the price of coal was read a second time in the House of Commons on Monday. Varying views are held with regard to it, and there may be some alterations made when the Committee stage is reached (p. 311).

WE explain the position with regard to the "model" wiring and fittings clause in relation to the position at Plymouth (p. 311).

MR. JUSTICE JOYCE on Tuesday dismissed the action for alleged infringement by Pope's Electric Lamp Co., Ltd., of the Just and Hanaman metal filament lamp patent No. 23,899 of 1904. The Osram Lamp Works, Ltd., will appeal, and it is intimated that the case will be carried to the House of Lords (p. 311).

An effect due to capacity on a three phase system is discussed in our Questions and Answers column (p. 312).

An example of electric driving of textile machinery is contained in an illustrated article (p. 313).

A DIVIDEND of 10 per cent. is recommended on the ordinary shares of Marconi's Wireless Telegraph Co., against 20 per cent. last year (p. 313).

AMONG the specifications published at the Patent Office last Thursday were several relating to metal filament lamps, and others in connection with commutator construction, electric railway control and locking lamp-holders (p. 314).

AT the annual meeting of the Tramways and Light Railways Association last week the serious position which has arisen owing to difficulty in obtaining supplies of wheels, axles, tyres, &c., was discussed. A paper was read on the electric vehicles as an adjunct to tramways, and experiments with a change speed mechanism were mentioned (p. 315).

A DESCRIPTION is given of the electric power installation in a bakery (p. 315).

A NEW electric fire is described (p. 316).

AN expenditure of £15,000 is contemplated at Barnsley; switchgear is required at Keighley; motors in Australia; cable and meters at Rotherham; cable at Aylesbury. The Bethnal Green supply scheme is to be proceeded with (p. 317).

THE "Northumberland" Clause has been imposed upon the Southampton Corporation in respect of a small extension of area.—A fault recently took place on the Oldham mains through a cable being laid in direct contact with a gas main.—A large extension scheme at St. Pancras is to be reduced by half owing to the war (p. 318).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING JULY 31ST, 1915.
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday, Wednesday, and Friday :—Drills 6.30 and 7.30.
Applications for Enrolment :—All applications for enrolment should be sent to the Commandant, Marconi House, Strand, from whom all particulars can be obtained.

E. G. FLEMING.
(Company Commander and Acting Adjutant.)

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

THE NATIONAL PHYSICAL LABORATORY

THE report of the National Physical Laboratory for the year ended March 31st, 1915, records that the work of the Laboratory has been greatly affected by the war. About 50 members of the total staff of 210 have joined the colours, and considerable reorganisation has been necessary. The financial results have been adversely affected. Up to the end of June the receipts for work done were considerably in excess of those for the corresponding three months of the previous year, but during July, August, and September there was a fall amounting to some £2,100. Since September, however, there has been a considerable recovery, and the results are less unsatisfactory than had been feared. When the call came for the formation of the new Army, it was clear that some selection would have to be made among those who wished to join; the demands on certain divisions of the Laboratory for work for war purposes were very severe, and many of the staff who were prepared to volunteer could not be spared. To these who were retained at Teddington the Government badge, "On War Service," has been issued; the rest entered various branches of the Services, and are now in various parts of the world. Some are at the Front, a large party joined the 6th East Surrey Regiment, and have gone to India. Dr. Kaye, as a Captain in the London Electrical Engineers, has had charge since August of the searchlights along a stretch of 150 miles at the mouth of the Thames. Mr. Millar went to Antwerp with the Royal Naval Volunteer Reserve, was taken prisoner, and is now at Döberitz. Forty-two members of the staff have been enrolled as special constables, and some take part in patrolling the grounds. Those remaining at the Laboratory have been very fully employed, and a large number of requests for advice and assistance have been received from the Admiralty and the War Office and other Government departments. In addition to the aeronautics work, the time of a number of the senior members of the staff has been given almost entirely to war research.

Amongst other activities during the year, it may be mentioned that the Committee on the Lighting of Factories and Workshops, of which the Director is Chairman, and Mr. Paterson Secretary, have completed their first report. The Director (Dr. Glazebrook) has been much occupied as Chairman of a sub-committee of the Engineering Standards Committee on the rating of electrical machinery. With regard to the work of the Physics Department, the report of the Executive Committee continues as follows:—

In the Electrical Standards Division Mr. F. E. Smith again calls attention to the great accuracy with which the fundamental electrical standards can be reproduced. It has not been possible to obtain the exact figures which result from the comparison made by Mr. F. E. Smith and Dr. Giebe between the absolute measurements of resistance at the National Physical Laboratory and the Reichsanstalt, but it is known that the agreement is very close. A comparison between five mercury resistance tubes made and calibrated at the N.P.L., and five constructed at Tokio, shows a mean difference of eight parts in one million, while Weston cells made at Petrograd were found to agree with the Laboratory Standards to within one part in one hundred thousand. The comparisons of some standards of inductance made by Dr. Giebe and Mr. Campbell are equally satisfactory. Mr. Campbell's valuable paper on the measurement of large high-frequency currents must be mentioned; he and Mr. Dye have extended the range and added to the accuracy of their high-frequency measurements in a marked manner. In the Alternating Current Measurements Division much has been done to improve the accuracy of the measurements and to accelerate the work. The increased volume of the work makes it necessary to increase the speed wherever possible, and additional equipment has been provided with this object. The tests in the direct current division have increased largely, in consequence of the war; the research work has dealt chiefly with the rise of temperature of underground cables, and thanks to the cordial co-operation of the engineers in a number of large centres, Mr. Melsom, who has devoted much time and energy to the work, has obtained a series of interesting results which will in due time be communicated to the Institution of Electrical Engineers, at whose cost the research is being carried out. Mr. Paterson has communicated to the Physical Society two most interesting photometric papers. One of these deals with the methods by which the values of the high-efficiency Electrical Standards have been determined, and the Committee take this opportunity of thanking the General Electric Co. for their generosity in presenting a very complete series of standard lamps made specially at the Osram Lamp Works. The other research has led to formulæ connecting the light emitted per watt with the temperature of the filament, for both carbon and tungsten lamps, and is of great interest.

The total number of electrical measurements made in the Physics Department during the year was 191, as against 259 for the previous year, but the tests in the electrotechnics division

increased from 3,823 to 5,080. In the Photometry Division, however, the number of tests declined from 1,142 to 410. Further details of the work of the various departments are given in the Director's report.

In the Metallurgical Department a new electrically-driven rolling mill has been put to work, and in connection with this a 1,000-ampere-hour 120-cell Tudor battery and a new motor booster set have been installed in the power house.

THE INVENTIONS BOARD

IN connection with the announcement made early in the month that Lord Fisher had been appointed Chairman of an Inventions Board which has been established to assist the Admiralty in co-ordinating and encouraging scientific effort in its application to the requirements of the Naval Service, it is now stated that the organisation of the Board has been completed. It will comprise a Central Committee and a Panel of Consultants consisting of scientific experts, who will advise the Central Committee on any matters referred to them.

The Central Committee will consist of Lord Fisher, Sir J. J. Thomson, F.R.S., the Hon. Sir C. A. Parsons, F.R.S., and Dr. G. T. Beilby, F.R.S.

The consulting panel will consist of the following, which, however, may be added to from time to time as events may prove necessary:—

Professor H. B. Baker, F.R.S. (Professor of Chemistry, Imperial College), Professor W. G. Bragg, F.R.S. (Professor of Physics, Leeds University), Professor H. C. H. Carpenter (Professor of Metallurgy, Imperial College), Sir William Crookes, O.M., F.R.S., W. Duddell, Esq., F.R.S., Professor Percy Frankland, F.R.S. (Professor of Chemistry, Birmingham University), Professor Betram Hopkinson, F.R.S., Sir Oliver Lodge, F.R.S., Professor W. J. Pope, F.R.S. (Professor of Chemistry, Cambridge), Sir Ernest Rutherford, F.R.S., G. Gerald Stoney, Esq., F.R.S., Professor the Hon. R. J. Strutt, F.R.S. (Professor of Physics, Imperial College).

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

Among the examination results in the Faculty of Engineering at the University of Bristol the following relate to the electrical engineering final examination for the certificate:—(Pass) R. J. Perry. Final examination for B.Sc. second-class honours, S. Bartlett; pass, E. G. Moody and L. G. H. Sarsfield.

The full four-year course in electrical engineering at the University of Birmingham, which qualifies for the degree of B.Sc., will commence as usual in the autumn, the session opening on October 5th. The electrical engineering department is under Professor G. Kapp, who is assisted by Messrs. E. J. Kipps and T. F. Wall as lecturers. The Principal of the University is Sir Oliver Lodge, F.R.S. Full particulars of the courses can be obtained from the Secretary.

The complete courses of instruction provided at the City and Guilds (Engineering) College, South Kensington, which forms the engineering section of the Imperial College of Science and Technology, lead up to and include the highest specialised instruction for students, with the object of fitting them to take leading positions as electrical engineers, investigators, advisers, and experts, and those qualified who desire to take up more advanced courses of training and research in connection with those branches in which they are specially interested. The department of electrical engineering is under the direction of Prof. T. Mather, F.R.S., and that of mechanical engineering and motive power is under Prof. W. E. Dalby, F.R.S. Further information may be obtained from the Registrar.

Half-watt Lamps for Street Lighting in New York.—According to the *Electrical World*, during the last six months upwards of 10,000 arc lamps have been replaced by an equal number of half-watt lamps of various sizes from 300 to 1,000 watts. While this substitution was made on a lamp-for-lamp basis, the size in each case was determined by the illumination demands of the immediate vicinity, as follows: Large squares at intersecting streets and junction points, 750-watt lamps; important thoroughfares, 500-watt lamps; crosstown thoroughfares, tree-lined or parked avenues, and streets and avenues with car lines, 400-watt lamps; mercantile and wholesale districts, residence streets and small parks, 300-watt lamps. Approximately 600 multiple-arc lamps in use on the bridges connecting the several boroughs have also been replaced by 300-watt gas-filled tungsten lamps. These lamps are divided between those of the bowl-frosted type, installed with socket housings having an elongated neck reflector coming well down over the neck of the lamp and without the usual globe inclosure, and those in standard housings. The lamps without inclosing globes are of the straight-sided, pear-shaped type, and have withstood local climatic conditions and traffic vibrations satisfactorily.

COAL SUPPLIES

THE Board of Trade introduced a Bill into Parliament on Wednesday last week limiting the price of coal. Briefly, it provides that the price at the pit-mouth shall not be more than four shillings per ton in excess of the price obtaining twelve months ago. In special circumstances the Board of Trade may increase this difference where the conditions warrant it. The Bill, however, does not apply to contracts already made.

This point has been a matter of some discussion, and opinions are held that the Bill, which passed its second reading in the House of Commons on Monday, is to a large extent useless for the purpose of keeping down prices during the coming winter, inasmuch as most contracts have already been entered into. The case for the Bill, however, is that in the absence of such a measure there would have been the likelihood of much higher prices being charged than last winter. On the whole, therefore, it would seem that electricity supply undertakings need not anticipate any appreciable reduction in their coal costs in the near future. The Board of Trade admits that the task of dealing with existing contracts would be much too complicated, but London merchants, at any rate, have agreed with the Government not to charge higher prices than are necessitated by the extra costs, and have placed their books at the disposal of the Board of Trade. This confirms the general view of London electricity undertakings which deal through merchants, viz., that throughout last winter the merchants did their utmost to act up to their pre-war contracts, and at the conference held at the Institution of Electrical Engineers several speakers mentioned this fact.

It is possible that when the Bill is considered in Committee some amendments will be made. It is significant that Sir Arthur Markham, a colliery owner, should protest against a standard increase of 4s. per ton. He suggests that 2s. would be nearer the extra cost to which colliery owners have been put. On the other hand, other colliery owners during the course of the second reading debate protested against the coal industry being singled out for treatment in this way, but a motion for the rejection of the Bill was withdrawn.

MUNICIPAL WIRING POWERS

THE reference on page 302 of our last issue to the fact that the "Model" Wiring Clause had been inserted in the Plymouth Corporation Bill by the Lord Chairman of Committees after a House of Lords Committee had granted the Corporation powers to wire without the intervention of a contractor, may perhaps need a little further explanation as to the meaning of the "Model" Clause. The authorities of Parliament who deal with private Bill legislation have a set of "Model" clauses capable of application to electric supply, railways, tramways, &c., which are added to and modified from time to time. These clauses relate to matters usually of a non-controversial nature, and represent for the time being the settled policy of Parliament with regard to these details. Consequently any promoter coming to Parliament for powers covered by these clauses has to show a very special case before any deviation from them will be allowed by those whose duty it is to scrutinise the Bills before they reach Committees of either House. This, of course, does not take away the right of the Committee to grant such powers as it thinks fit, but, as in the Plymouth case, alterations can be made even after a Committee has given its decision in favour of a modification of the "Model" Clause.

The position with regard to the "Model" Wiring Clause is that, before the introduction of the first I.M.E.A. Bill, a clause was introduced into the set of "Model" clauses stipulating that where a municipal undertaking takes powers to wire and fit consumers' premises the work must be placed in the hands of a contractor. This has been the uniform practice since that date, and, of course, the strong opposition to the I.M.E.A. Bill has been due to the fact that this latter would modify the present "Model" Clause. If the I.M.E.A. Bill had been passed, the "Model" Clause would have been altered accordingly. As pointed out on page 127 of our issue for March 5th, however, the latest I.M.E.A. Bill differs in many respects from its predecessors, for it concedes to the contractors the point that all wiring work shall be sub-let to a contractor where there is more than one electrical contractor in the district, giving to municipalities, however, the powers to hire and sell electric lighting and heating apparatus with due protection to the contractors from any under-selling. But this, as our readers know, does not meet with the approval of the contractors except in Scotland. Still, it is obvious that

at the present time no good purpose would be served in introducing the I.M.E.A. Bill into Parliament even if an opportunity could be found.

THE OSRAM v. POPE PATENT ACTION

Judgment for Pope Co.

M R. JUSTICE JOYCE gave judgment on Tuesday in the action by the Osram Lamp Works, Ltd., for alleged infringement by Pope's Electric Lamp Co. of the Just and Hanaman patent No. 23,899 of 1904. The proceedings in the case were reported in our issues for July 1st, p. 288; July 8th, p. 294; and July 15th, p. 304. Premising his remarks by stating he had received the hint that the case would go to the House of Lords on appeal, Mr. Justice Joyce read the following passage from the specification as constituting the material part of it for the purposes of the action and as representing the process described by the patentees :—

For the manufacture of filaments of this kind finely divided tungsten or tungsten compounds such as tungstite, tungstic acid, or tungstic sulphide as mixed with an organic binding medium, such as collodion or a solution of cellulose in chloride of zinc or cupreous ammonia oxide or the like, from which mass filaments are formed in the usual manner, and are then carbonised, in some instances after denitration has previously been effected. The filaments so produced and consisting of tungsten and carbon are then submitted to the following further treatment.

First of all the carbon, which has only served as a binding medium, is removed by subjecting the filaments to the passage of current in an atmosphere of steam and hydrogen, and thus raising it to a high temperature. By this process the carbon is completely oxidised so as to form carbonic oxide and a filament of tungsten is left. These filaments are then rendered uniform in a manner similar to that employed in the treatment of the usual carbon filaments, by submitting them to the action of current in an atmosphere of volatile tungsten compounds in the presence of a large quantity of hydrogen whereby the tungsten deposited equalises the filaments. The filaments which have been rendered uniform in this way are then sealed in glass bulbs in the usual manner, and these latter are exhausted.

It appeared from the evidence, continued his Lordship, that the usual manner of forming filaments referred to in the above extract from the specification was to make the materials into what was termed a compound having the consistency of thick treacle, which was then squirted through a glass nozzle. The defendants, however, made a much thicker paste. Then there was the question of carbonisation. The specification carried this out in the usual manner, and there was some dispute as to whether defendants carried out their carbonisation in the usual manner. It was denied with some show of reason that the defendants did so. He had some doubt whether they did so or not, but as to whether the defendants used the series of processes described in the patent, or, indeed, any of them, he did not feel much doubt. Rightly or wrongly, he did not think they used any one of them. They certainly did not pass a current through the filament, and the filaments were not subjected to the passage of current in an atmosphere of steam and hydrogen. In his opinion the defendants did not use an atmosphere of steam and hydrogen in the sense in which the phrase was used in the specification or was intended by the patentees; nor, indeed, did the defendants use steam at all in the ordinary sense of the word. He understood steam to be water-vapour. The dictionary he had consulted described steam as "the hot vapour given off at boiling point," although it was added that true steam was invisible, the white cloud termed steam being a collection of fine drops of water formed by condensation. The hydrogen used by the defendants was dry, but it was said by the plaintiffs that an infinitesimal amount of water-vapour was formed during the process which constituted steam in the scientific sense. That might be so, but it was certainly not subjecting the filaments to the passage of a current in an atmosphere of steam and hydrogen, as described or indicated in the patent. Nor was the defendants' process an equivalent process. In the circumstances, seeing how many of the steps described in the specification were omitted from the method adopted by the defendants, and alleged to constitute infringement, he was unable to bring himself to the conclusion that the patent had been infringed by the defendants. He therefore held that the patent had not been infringed, and the action must be dismissed with the usual costs.

As to the validity of the patent, had it been necessary for him to go into this, he would have had serious doubts on the matter, not only as to subject matter, but as to the sufficiency of the instructions given by the patentees.

It was intimated that the Osram Lamp Works, Ltd., will give notice of appeal immediately.

THE NATIONAL PHYSICAL LABORATORY

THE report of the National Physical Laboratory for the year ended March 31st, 1915, records that the work of the Laboratory has been greatly affected by the war. About 50 members of the total staff of 210 have joined the colours, and considerable reorganisation has been necessary. The financial results have been adversely affected. Up to the end of June the receipts for work done were considerably in excess of those for the corresponding three months of the previous year, but during July, August, and September there was a fall amounting to some £2,100. Since September, however, there has been a considerable recovery, and the results are less unsatisfactory than had been feared. When the call came for the formation of the new Army, it was clear that some selection would have to be made among those who wished to join; the demands on certain divisions of the Laboratory for work for war purposes were very severe, and many of the staff who were prepared to volunteer could not be spared. To these who were retained at Teddington the Government badge, "On War Service," has been issued; the rest entered various branches of the Services, and are now in various parts of the world. Some are at the Front, a large party joined the 6th East Surrey Regiment, and have gone to India. Dr. Kaye, as a Captain in the London Electrical Engineers, has had charge since August of the searchlights along a stretch of 150 miles at the mouth of the Thames. Mr. Millar went to Antwerp with the Royal Naval Volunteer Reserve, was taken prisoner, and is now at Döberitz. Forty-two members of the staff have been enrolled as special constables, and some take part in patrolling the grounds. Those remaining at the Laboratory have been very fully employed, and a large number of requests for advice and assistance have been received from the Admiralty and the War Office and other Government departments. In addition to the aeronautics work, the time of a number of the senior members of the staff has been given almost entirely to war research.

Amongst other activities during the year, it may be mentioned that the Committee on the Lighting of Factories and Workshops, of which the Director is Chairman, and Mr. Paterson Secretary, have completed their first report. The Director (Dr. Glazebrook) has been much occupied as Chairman of a sub-committee of the Engineering Standards Committee on the rating of electrical machinery. With regard to the work of the Physics Department, the report of the Executive Committee continues as follows:—

In the Electrical Standards Division Mr. F. E. Smith again calls attention to the great accuracy with which the fundamental electrical standards can be reproduced. It has not been possible to obtain the exact figures which result from the comparison made by Mr. F. E. Smith and Dr. Giebe between the absolute measurements of resistance at the National Physical Laboratory and the Reichsanstalt, but it is known that the agreement is very close. A comparison between five mercury resistance tubes made and calibrated at the N.P.L., and five constructed at Tokio, shows a mean difference of eight parts in one million, while Weston cells made at Petrograd were found to agree with the Laboratory Standards to within one part in one hundred thousand. The comparisons of some standards of inductance made by Dr. Giebe and Mr. Campbell are equally satisfactory. Mr. Campbell's valuable paper on the measurement of large high-frequency currents must be mentioned; he and Mr. Dye have extended the range and added to the accuracy of their high-frequency measurements in a marked manner. In the Alternating Current Measurements Division much has been done to improve the accuracy of the measurements and to accelerate the work. The increased volume of the work makes it necessary to increase the speed wherever possible, and additional equipment has been provided with this object. The tests in the direct current division have increased largely, in consequence of the war; the research work has dealt chiefly with the rise of temperature of underground cables, and thanks to the cordial co-operation of the engineers in a number of large centres, Mr. Melsom, who has devoted much time and energy to the work, has obtained a series of interesting results which will in due time be communicated to the Institution of Electrical Engineers, at whose cost the research is being carried out. Mr. Paterson has communicated to the Physical Society two most interesting photometric papers. One of these deals with the methods by which the values of the high-efficiency Electrical Standards have been determined, and the Committee take this opportunity of thanking the General Electric Co. for their generosity in presenting a very complete series of standard lamps made specially at the Osram Lamp Works. The other research has led to formulae connecting the light emitted per watt with the temperature of the filament, for both carbon and tungsten lamps, and is of great interest.

The total number of electrical measurements made in the Physics Department during the year was 191, as against 259 for the previous year, but the tests in the electrotechnics division

increased from 3,823 to 5,080. In the Photometry Division, however, the number of tests declined from 1,142 to 410. Further details of the work of the various departments are given in the Director's report.

In the Metallurgical Department a new electrically-driven rolling mill has been put to work, and in connection with this a 1,000-ampere-hour 120-cell Tudor battery and a new motor booster set have been installed in the power house.

THE INVENTIONS BOARD

IN connection with the announcement made early in the month that Lord Fisher had been appointed Chairman of an Inventions Board which has been established to assist the Admiralty in co-ordinating and encouraging scientific effort in its application to the requirements of the Naval Service, it is now stated that the organisation of the Board has been completed. It will comprise a Central Committee and a Panel of Consultants consisting of scientific experts, who will advise the Central Committee on any matters referred to them.

The Central Committee will consist of Lord Fisher, Sir J. J. Thomson, F.R.S., the Hon. Sir C. A. Parsons, F.R.S., and Dr. G. T. Beilby, F.R.S.

The consulting panel will consist of the following, which, however, may be added to from time to time as events may prove necessary:—

Professor H. B. Baker, F.R.S. (Professor of Chemistry, Imperial College), Professor W. G. Bragg, F.R.S. (Professor of Physics, Leeds University), Professor H. C. H. Carpenter (Professor of Metallurgy, Imperial College), Sir William Crookes, O.M., F.R.S., W. Duddell, Esq., F.R.S., Professor Percy Frankland, F.R.S. (Professor of Chemistry, Birmingham University), Professor Betram Hopkinson, F.R.S., Sir Oliver Lodge, F.R.S., Professor W. J. Pope, F.R.S. (Professor of Chemistry, Cambridge), Sir Ernest Rutherford, F.R.S., G. Gerald Stoney, Esq., F.R.S., Professor the Hon. R. J. Strutt, F.R.S. (Professor of Physics, Imperial College).

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

Among the examination results in the Faculty of Engineering at the University of Bristol the following relate to the electrical engineering final examination for the certificate:—(Pass) R. J. Perry. Final examination for B.Sc. second-class honours, S. Bartlett; pass, E. G. Moody and L. G. H. Sarsfield.

The full four-year course in electrical engineering at the University of Birmingham, which qualifies for the degree of B.Sc., will commence as usual in the autumn, the session opening on October 5th. The electrical engineering department is under Professor G. Kapp, who is assisted by Messrs. E. J. Kipps and T. F. Wall as lecturers. The Principal of the University is Sir Oliver Lodge, F.R.S. Full particulars of the courses can be obtained from the Secretary.

The complete courses of instruction provided at the City and Guilds (Engineering) College, South Kensington, which forms the engineering section of the Imperial College of Science and Technology, lead up to and include the highest specialised instruction for students, with the object of fitting them to take leading positions as electrical engineers, investigators, advisers, and experts, and those qualified who desire to take up more advanced courses of training and research in connection with those branches in which they are specially interested. The department of electrical engineering is under the direction of Prof. T. Mather, F.R.S., and that of mechanical engineering and motive power is under Prof. W. E. Dalby, F.R.S. Further information may be obtained from the Registrar.

Half-watt Lamps for Street Lighting in New York.—According to the *Electrical World*, during the last six months upwards of 10,000 arc lamps have been replaced by an equal number of half-watt lamps of various sizes from 300 to 1,000 watts. While this substitution was made on a lamp-for-lamp basis, the size in each case was determined by the illumination demands of the immediate vicinity, as follows: Large squares at intersecting streets and junction points, 750-watt lamps; important thoroughfares, 500-watt lamps; crosstown thoroughfares, tree-lined or parked avenues, and streets and avenues with car lines, 400-watt lamps; mercantile and wholesale districts, residence streets and small parks, 300-watt lamps. Approximately 600 multiple-arc lamps in use on the bridges connecting the several boroughs have also been replaced by 300-watt gas-filled tungsten lamps. These lamps are divided between those of the bowl-frosted type, installed with socket housings having an elongated neck reflector coming well down over the neck of the lamp and without the usual globe inclosure, and those in standard housings. The lamps without inclosing globes are of the straightsided, pear-shaped type, and have withstood local climatic conditions and traffic vibrations satisfactorily.

COAL SUPPLIES

THE Board of Trade introduced a Bill into Parliament on Wednesday last week limiting the price of coal. Briefly, it provides that the price at the pit-mouth shall not be more than four shillings per ton in excess of the price obtaining twelve months ago. In special circumstances the Board of Trade may increase this difference where the conditions warrant it. The Bill, however, does not apply to contracts already made.

This point has been a matter of some discussion, and opinions are held that the Bill, which passed its second reading in the House of Commons on Monday, is to a large extent useless for the purpose of keeping down prices during the coming winter, inasmuch as most contracts have already been entered into. The case for the Bill, however, is that in the absence of such a measure there would have been the likelihood of much higher prices being charged than last winter. On the whole, therefore, it would seem that electricity supply undertakings need not anticipate any appreciable reduction in their coal costs in the near future. The Board of Trade admits that the task of dealing with existing contracts would be much too complicated, but London merchants, at any rate, have agreed with the Government not to charge higher prices than are necessitated by the extra costs, and have placed their books at the disposal of the Board of Trade. This confirms the general view of London electricity undertakings which deal through merchants, viz., that throughout last winter the merchants did their utmost to act up to their pre-war contracts, and at the conference held at the Institution of Electrical Engineers several speakers mentioned this fact.

It is possible that when the Bill is considered in Committee some amendments will be made. It is significant that Sir Arthur Markham, a colliery owner, should protest against a standard increase of 4s. per ton. He suggests that 2s. would be nearer the extra cost to which colliery owners have been put. On the other hand, other colliery owners during the course of the second reading debate protested against the coal industry being singled out for treatment in this way, but a motion for the rejection of the Bill was withdrawn.

MUNICIPAL WIRING POWERS

THE reference on page 302 of our last issue to the fact that the "Model" Wiring Clause had been inserted in the Plymouth Corporation Bill by the Lord Chairman of Committees after a House of Lords Committee had granted the Corporation powers to wire without the intervention of a contractor, may perhaps need a little further explanation as to the meaning of the "Model" Clause. The authorities of Parliament who deal with private Bill legislation have a set of "Model" clauses capable of application to electric supply, railways, tramways, &c., which are added to and modified from time to time. These clauses relate to matters usually of a non-controversial nature, and represent for the time being the settled policy of Parliament with regard to these details. Consequently any promoter coming to Parliament for powers covered by these clauses has to show a very special case before any deviation from them will be allowed by those whose duty it is to scrutinise the Bills before they reach Committees of either House. This, of course, does not take away the right of the Committee to grant such powers as it thinks fit, but, as in the Plymouth case, alterations can be made even after a Committee has given its decision in favour of a modification of the "Model" Clause.

The position with regard to the "Model" Wiring Clause is that, before the introduction of the first I.M.E.A. Bill, a clause was introduced into the set of "Model" clauses stipulating that where a municipal undertaking takes powers to wire and fit consumers' premises the work must be placed in the hands of a contractor. This has been the uniform practice since that date, and, of course, the strong opposition to the I.M.E.A. Bill has been due to the fact that this latter would modify the present "Model" Clause. If the I.M.E.A. Bill had been passed, the "Model" Clause would have been altered accordingly. As pointed out on page 127 of our issue for March 5th, however, the latest I.M.E.A. Bill differs in many respects from its predecessors, for it concedes to the contractors the point that all wiring work shall be sub-let to a contractor where there is more than one electrical contractor in the district, giving to municipalities, however, the powers to hire and sell electric lighting and heating apparatus with due protection to the contractors from any under-selling. But this, as our readers know, does not meet with the approval of the contractors except in Scotland. Still, it is obvious that

at the present time no good purpose would be served in introducing the I.M.E.A. Bill into Parliament even if an opportunity could be found.

THE OSRAM v. POPE PATENT ACTION

Judgment for Pope Co.

M R. JUSTICE JOYCE gave judgment on Tuesday in the action by the Osram Lamp Works, Ltd., for alleged infringement by Pope's Electric Lamp Co. of the Just and Hanaman patent No. 23,899 of 1904. The proceedings in the case were reported in our issues for July 1st, p. 283; July 8th, p. 294; and July 15th, p. 304. Premising his remarks by stating he had received the hint that the case would go to the House of Lords on appeal, Mr. Justice Joyce read the following passage from the specification as constituting the material part of it for the purposes of the action and as representing the process described by the patentees :—

For the manufacture of filaments of this kind finely divided tungsten or tungsten compounds such as tungstite, tungstic acid, or tungstic sulphide as mixed with an organic binding medium, such as collodion or a solution of cellulose in chloride of zinc or cupreous ammonia oxide or the like, from which mass filaments are formed in the usual manner, and are then carbonised, in some instances after denitration has previously been effected. The filaments so produced and consisting of tungsten and carbon are then submitted to the following further treatment.

First of all the carbon, which has only served as a binding medium, is removed by subjecting the filaments to the passage of current in an atmosphere of steam and hydrogen, and thus raising it to a high temperature. By this process the carbon is completely oxidised so as to form carbonic oxide and a filament of tungsten is left. These filaments are then rendered uniform in a manner similar to that employed in the treatment of the usual carbon filaments, by submitting them to the action of current in an atmosphere of volatile tungsten compounds in the presence of a large quantity of hydrogen whereby the tungsten deposited equalises the filaments. The filaments which have been rendered uniform in this way are then sealed in glass bulbs in the usual manner, and these latter are exhausted.

It appeared from the evidence, continued his Lordship, that the usual manner of forming filaments referred to in the above extract from the specification was to make the materials into what was termed a compound having the consistency of thick treacle, which was then squirted through a glass nozzle. The defendants, however, made a much thicker paste. Then there was the question of carbonisation. The specification carried this out in the usual manner, and there was some dispute as to whether defendants carried out their carbonisation in the usual manner. It was denied with some show of reason that the defendants did so. He had some doubt whether they did so or not, but as to whether the defendants used the series of processes described in the patent, or, indeed, any of them, he did not feel much doubt. Rightly or wrongly, he did not think they used any one of them. They certainly did not pass a current through the filament, and the filaments were not subjected to the passage of current in an atmosphere of steam and hydrogen. In his opinion the defendants did not use an atmosphere of steam and hydrogen in the sense in which the phrase was used in the specification or was intended by the patentees; nor, indeed, did the defendants use steam at all in the ordinary sense of the word. He understood steam to be water-vapour. The dictionary he had consulted described steam as "the hot vapour given off at boiling point," although it was added that true steam was invisible, the white cloud termed steam being a collection of fine drops of water formed by condensation. The hydrogen used by the defendants was dry, but it was said by the plaintiffs that an infinitesimal amount of water-vapour was formed during the process which constituted steam in the scientific sense. That might be so, but it was certainly not subjecting the filaments to the passage of a current in an atmosphere of steam and hydrogen, as described or indicated in the patent. Nor was the defendants' process an equivalent process. In the circumstances, seeing how many of the steps described in the specification were omitted from the method adopted by the defendants, and alleged to constitute infringement, he was unable to bring himself to the conclusion that the patent had been infringed by the defendants. He therefore held that the patent had not been infringed, and the action must be dismissed with the usual costs.

As to the validity of the patent, had it been necessary for him to go into this, he would have had serious doubts on the matter, not only as to subject matter, but as to the sufficiency of the instructions given by the patentees.

It was intimated that the Osram Lamp Works, Ltd., will give notice of appeal immediately.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,452.

Below are two diagrams of a three-phase star delta starting-switch showing contacts made when in the starting and running positions. Please show connections to motor terminals and mains. In Fig. 2 numbers 1 and 4 terminals are the ends of one circuit as tested by a lamp, also numbers 2 and 5, 3 and 6, two other circuits. The terminals of another motor are lettered

Fig.1.

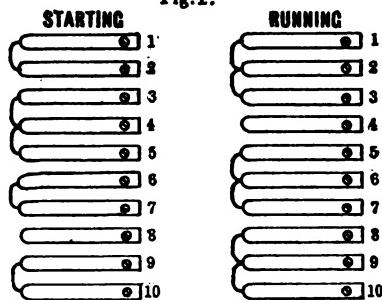

Fig.2.

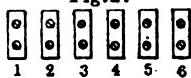

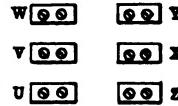

Fig.3.

as in sketch 3. As received from the makers, the terminals marked X Y Z are short-circuited. Could this motor be coupled to a star delta starting-switch? Why is the lettering of the two top terminals on the right reversed? W and Y are not the ends of one circuit, as there are 13 megohms between them. Give a diagram showing the connection of the terminals to motor windings.

(Replies must be received not later than first post, Thursday, July 30th.)

ANSWERS TO No. 1,450.

I am in charge of the electrical plant at a large works. The current is supplied to us through a 1,200-kw. 6,000-500-volt three-phase transformer, and drives a large number of induction motors. The star-point of the transformer is not earthed. I have tested all motors and feeders to earth with the megger, and I get a good test; but when I put the current on, I get a faint glow on two 220-volt lamps connected in series from all three phases to earth. I afterwards placed one 220-volt lamp across each phase to earth, but I only got the same faint glow. I then switched the current off the transformer, and I tested

the low-tension side of transformer when in circuit with ten feeders and distribution-boxes up to the motor switches. I got a test of 600,000 ohms on all phases to earth. The current was then switched on the feeders, but I still get the same faint glow on the lamps as before. The question is: Why do I get a glow on the lamps, and why only the same glow on the single lamp? If there is leakage to earth there must be a short on at least two phases through earth, but I have no fuses blown.—"PELICAN."

The first award (10s.) is made to "H. H. H." for the following reply:—

The reason "Pelican" is able to obtain a faint glow on his testing lamps is due entirely to the effects of capacity current on his system. Any system of insulated conductors acts as a condenser, in which certain conductors act as one plate of the condenser, and other conductors and earth act as the other plate. On connecting the lamp or lamps to any phase and earth, capacity currents of the other phases will charge and discharge through the lamps. The reason the single lamp allows only the same as the two in series is explained by the fact that the vectorial sum of two quantities in quadrature when one is much smaller than the other is very slightly greater than the greater of the two quantities. In the case under consideration we have the lamp resistance in series with the capacity admittance or reactance, and assuming each lamp has a resistance when glowing of 800 ohms and the capacity reactance is 4,000 ohms, the impedance = $\sqrt{4,000^2 + 800^2} = 4,080$ ohms. When two lamps are used, and assuming the total lamp resistance is 1,600 ohms, the total impedance is = $\sqrt{4,000^2 + 1,600^2} = 4,308$ ohms. In the first case the current flowing through the lamp is 0.122 amp., and in the second case the current is 0.114, a difference of only about 7 per cent.

The second award (5s.) is given to "E. H.," who writes as follows:—

The tests referred to in the question are quite sufficient to show that the insulation of the system is quite satisfactory, and that the glow of the lamps is not due to a fault. The only other cause that could produce the phenomena noticed is the condenser action between the system and earth: the transformer and motor windings are wound on iron cores, which are most probably well earthed; the feeders, especially if underground, also have some capacity. Suppose the lamps employed for testing had carbon filaments and absorbed, say, 60 watts each at their rated voltage. Now filament lamps glow with about half their normal voltage, so that the corresponding current would be $\frac{1}{2} \times \frac{60}{220} = 0.136$ amp. (neglecting change in resistance). Also, resistance of one lamp = $\frac{220}{0.272} = 810$ ohms. The capacity of the transformers and motors is distributed over the three phases. Suppose that Z be the reactance, which when connected across 500 volts gives the same current as that produced by the actual capacity of the three-phase system in question. Then with two lamps connected to earth

$$I = \frac{E}{\sqrt{R^2 + Z^2}}$$

$$\therefore 0.136 = \frac{500}{\sqrt{(1620)^2 + Z^2}}$$

$$\therefore Z = 3300$$

When there is only one lamp connected between the line and earth, we have

$$I = \frac{500}{\sqrt{(810)^2 + (3300)^2}} = 0.147.$$

That is, inserting one lamp instead of two between the line and earth only increases the current from 0.136 to 0.147 ampere, so that the single lamp would no more than glow. If the current through the lamps is less than half the normal value (as indeed is probably the case, since the glow is "faint"), the increase in current obtained by removing one lamp is less than that given above. It may be mentioned that any harmonics present either in the phase or in the line voltages would assist in accentuating this phenomenon.

ANSWER TO CORRESPONDENT

E. H. G. (Natal).—The Managing Director of the National Electric Construction Co. is Mr. W. B. Cownie. The address is 3 Laurence Pountney Hill, E.C.

AN INDIVIDUAL DRIVEN DOUBLING FRAME INSTALLATION

PREPARED TO laying down their new doubling frame installation at their new Arden Works, King Cross, Halifax, Messrs. S. Thornton & Co., Ltd. fully investigated the different systems of drive available, and after a brief examination of the factors involved electricity was selected, one of the determining factors being that electric power is supplied by the Halifax Corporation at a comparatively low rate, especially when the mill runs at

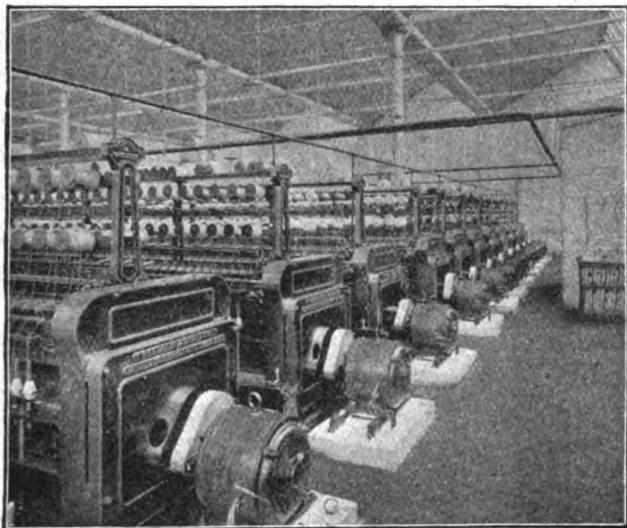

FIG. 1.—A VIEW OF 7 H.P. "WITTON" MOTORS DRIVING THE DOUBLING FRAMES.

night time. On the advice of their consulting engineer and also of the Textile Department of the General Electric Co., Ltd., individual drive was installed. The installation aggregates about 100 h.p., and the machines comprised in this installation are:—Twelve ring-doubling frames of 300 spindles, eight power reels, four 60-drum winding frames, 120 bobbins each, one 120-drum winding frame, one bundling press, one preparing machine.

The Halifax Corporation has installed in the mill a 100-kw. three-phase 6,600-volt 50-cycle transformer, to reduce the

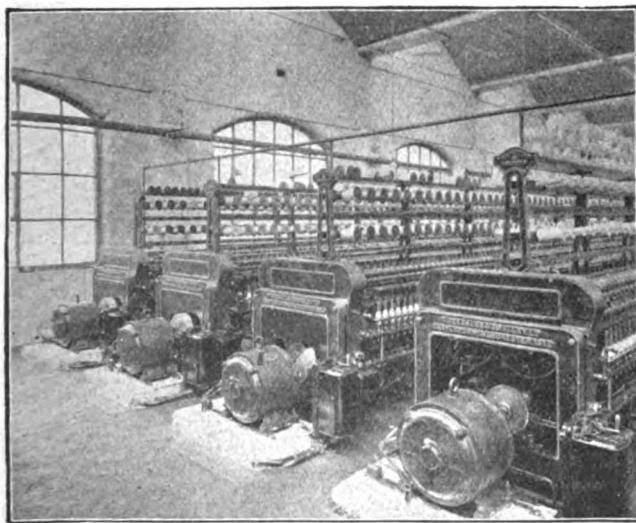

FIG. 2.—DETAILED VIEW OF THE MOTORS AND STARTING SWITCH-GEAR, SHOWING COVERS REMOVED FROM THE GEARS.

supply pressure to 220 volts, as this is the most suitable for small individual drive motors. The electrical equipment was entrusted to the Textile Department of the General Electric Co., Ltd. (of Wellington Street, Leeds, and 67 Queen Victoria Street, London, E.C.).

The problems involved in the individual driving of the doubling frames required close attention. Usually the tin roller shafts on doubling frames are run at a speed of from 800 to 1,000 r.p.m., but in this case the frame-makers required a speed not exceeding 880 to 900 r.p.m. As the nearest motor speed on a 50-cycle supply was between 960

and 970 r.p.m., direct coupling was out of the question. In consequence, it was decided to use 7-h.p. "Witton" squirrel-cage protected type textile motors with ball bearings, running at a speed of 1,450 r.p.m., the motors being fitted with machine-cut double helical gear, made by the Power Plant Co., Ltd. The larger gear wheel is keyed directly to the frame shaft. The power at 220 volts is distributed to the machines from a compactly designed "Witton" switchboard, enclosed in a sheet-iron case, the cables being carried underground in conduit to a point close to the motors. The motors are started by means of ironclad starters, a set of fuses, also in a cast-iron case, being included in the motor circuit, when the starter is in the running position. A general view of the twelve "Witton" motors driving the doubling frames is shown in Fig. 1, and a more detailed view of the motors and switchgear in Fig. 2.

Although this installation is on a small scale, it has thoroughly proved the claims made for the individual electric drive. It has shown, *inter alia*, that the individual drive effects a considerable saving in power and space as well as in the cost of the buildings. The absence of belting and shafting has permitted the buildings to be of a lightly constructed type, and at the same time the illumination is very good. Electric driving has also resulted in an increased and improved production. The machines run with great steadiness, and at the same time maintenance is reduced to a minimum, and the ability to run individual machines on overtime without keeping an engine-room staff at work is a very great convenience.

The buildings are lighted throughout by Osram Axial type lamps, with an obscured reflector fitting close to the lamp. The lights are arranged down the doubling frames. The installation has now been running nearly a year, and although there is naturally considerable vibration, only one lamp has been broken, and that through being dropped on the floor.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

A Paper on the use of unbroken alternating current for cable telegraphy by Lt.-Col. G. O. Squier was read at a recent meeting of the Physical Society. The Paper proposes a new point of view in the method of transmission of signals in the submarine telegraph cable, and describes some apparatus for operating on the general principles involved. An ocean cable is considered as a power line, and starting with the standard form of circuit which would be used in case it were required to operate an electric motor through an ocean cable, experiments are described to determine the minimum possible variations required in such a circuit to permit the alternating current received to be interpreted in dots, dashes, and spaces of the present alphabet. The uninterrupted alternating current used in transmission is operated on synchronously by the ordinary transmitting tape, so as to alter the impedance of the transmitting circuit at the instants when the current is naturally zero. Dots, dashes, and spaces are each sent by semi-waves of either sign, but of different amplitudes. The alternating current received may be read directly from the record made by a siphon recorder, or this current may be employed to operate a siphon Morse printer, by means of an adaptation of Muirhead's gold-wire relay, or a Heartley magnifier and a local wire relay. The voltage stress along an Atlantic cable when an alternator is employed is shown, and the transmitting impedance of such a cable is computed as the frequency varies. A special form of cable dynamo to operate at frequencies from 4 to 10 was used in the experiments described. The fundamental principle is developed of never metallically "breaking" the transmitter circuit, which permits of greater accuracy in balancing the duplex bridge.

The directors of Marconi's Wireless Telegraph Co. recommend a dividend of 10 per cent. on the ordinary shares and 7 per cent. on the preference shares for the year ended December 31st, 1914. These compare with dividends of 20 per cent. and 17 per cent. respectively in the previous twelve months, and in view of conditions generally and the amount of work which the Company has had to do on behalf of the Government (in respect of which no account is taken in this balance sheet) it is not felt that the result is really so unsatisfactory as the diminution in dividends might at first sight suggest. The net profit for the year was £232,700, which represents an increase of £110,892 over the previous year. A very much smaller amount, however, was carried forward from the previous twelve months, and the available surplus was only £40,000 higher than in 1913, after transferring £100,000 to reserve.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is, Strictly Copyright.)

Specifications Published July 15th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad

24,029/13. Metal Filament Lamps. C. GLADITZ. Metal filament lamps with an inner bulb containing ammonia gas and an outer bulb forming a vacuum jacket acting as a heat insulator and preventing the outer glass from becoming porous. (Three figures.)

7,682/14. Metal Filament Lamps. B.T.-H. Co. (G.E. Co., U.S.A.). Gas-filled tungsten lamps in which an electrically-charged screen of wire netting is provided near the filament in a position to intercept the convection currents of gas before they reach the bulb, and to arrest the tungsten particles driven off from the filament before they can blacken the bulb. (One figure.)

7,779/14. Commutators. SIEMENS BROS. DYN. Wks., LTD., C. P. BRAMLEY, and T. A. WISDOM. A commutator in which the end faces of the bars are recessed and filled in flush with non-shrinking insulating material with the object of lessening the liability to breakdown between the end ring and the surface. (Four figures.)

8,385/14. Starting Rotary Converters. E. ROSENBERG. An arrangement for starting a rotary converter provided with a booster, comprising extra windings or tappings from the transformer supplying the converter and switches by which a voltage less than the full voltage can be applied to the armature of the booster to cause it to start up as a motor. When the desired speed has been attained, the full voltage is applied to the converter armature through the booster armature. (Two figures.)

14,984/14. Electric Railway System. C. E. H. HOBBHOUSE, W. SLINGO, H. C. GUNTON, and C. H. DOUGLAS. An improved electric railway system partly worked by remote control and partly automatically in which the conductor rail supplying the train motor armatures is divided into insulated sections and the potential applied to the train motors is controlled by an automatically-effected adjustment of the rheostat in the field circuit of the generator supplying that section. (One figure.)

15,489/14. Locking Lampholder. F. JONES. A locking lampholder for lamps with special caps, having a recess in the holder and flat spring in the cap (or vice versa) to co-operate with the recess by engaging with it to lock the lamp in, and to take the thrust of the contact plugs. A covered key channel is formed between the lamp and the holder by which a special tool may be inserted to deflect the spring when the lamp is to be removed. (Five figures.)

21,435/14. Metal Filament Lamps. B.T.-H. Co. (G.E. Co., U.S.A.). Gas-filled or other focus lamps with the filament in the form of two concentric helices, the outer one of which may be of greater resistance per unit length than the inner one, and may be coiled more loosely. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Arc Lamps: PLANIWERKE A.G. FÜR KOHLENFABRIKATION [Arc lamps] 15,485/14.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: MENZEL [Insulating tubes] 25,362/13; ARNO [Distribution systems] 3,280/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Motor control] 12,941/14; MICANITE & INSULATORS Co. and ALLAN [Insulating materials] 16,027/14; WOODHOUSE and CALLENDER'S CABLE & CONSTRUCTION Co. [Terminal boxes] 18,761/14.

Dynamos, Motors and Transformers: ROUTIN [Motor control] 683/14; J. STONE & Co. and DARKER [Dynamos] 7,589/14 and 7,590/14; KOCSIS and LÜCÖ [Driving dynamos] 23,686/14.

Heating and Cooking: FRANK [Radiators] 24,827/13; GOOD and WOODHOUSE [Heating elements] 19,484/14.

Ignition: CONNER [Magneto] 20,330/14; KETTERING and CHRYSST [Ignition system] 7,813/15.

Incandescent Lamps: KNIGHT and CLERK [Incandescent lamps] 16,007/14.

Instruments and Meters: WAHN [Fault localiser] 25,701/13; A.E.G. [Regulation of phase displacement in induction meters] 3,912/14; DRANSFIELD [A.C. voltmeters] 5,676/14.

Switchgear, Fuses and Fittings: SIEMENS BROS. DYN. Wks.,

KOETTGEN, and BOLTON [Switchgear] 25,072/13; WADE (Kaisser) [Switches] 313/14; GREEN [Switchboards] 953/14; DRESLA [Time switches] 8,504/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Circuit controlling devices] 16,327/14; RAILING and GARRARD [Relays] 16,575/14; COLLIE [Lampholders] 20,580/14; BURDON (Siemens & Halske A.G.) [Relays] 21,936/14; REASON [Switch and fuse boxes] 945/15.

Telephony and Telegraphy: SIEMENS & HALSKE A.G. [Telephone circuits] 1,871/14; SYKES [Relays for wireless telephony] 7,922/14; DRUMAUX [Telephone relay] 8,794/14; KUHR and BRIDGES [Wave detector] 9,686/14; OGILVIE and CREED, BILLE & Co. [Telegraphy] 11,222/14; HART [Transmission of pictures of moving objects] 15,270/14; AUTOMATIC TELEPHONE MANUFACTURING CO. (Automatic Electric Co., U.S.A.) [Telephone systems] 15,338/14; WHITE and PARSONS [Intercommunication telephones] 15,727/14; GALLETTI and GALLETTI'S WIRELESS TELEGRAPH & TELEPHONE CO. The Accurate Measurement of Resistance.—At a recent meeting of the Physical Society a Paper was read by Mr. E. H. Rayner describing methods by which the comparison of resistances can be made to an accuracy of 1 in 10,000 or higher by using simple apparatus usually available in electrical laboratories, or which can be easily constructed with little skilled assistance. The comparison of nominally equal resistances of 1 ohm and upwards by the usual method of shunting one side of a nearly balanced quadrilateral by a high resistance was mentioned. Variations on this when only part of one resistance is shunted were often useful. The advantages of having resistances capable of carrying comparatively large currents were illustrated, especially for measuring changes of resistance of commercial apparatus under working conditions. The determination of errors in a volt box for use with a potentiometer was described at some length. If a sufficient continuous-current voltage was not available for testing such apparatus as high-potential dividers, it was shown that using sufficient continuous current to secure sensitivity the heating might be supplied by superposed alternating current. Resistances in common use were generally of simple numerical value, and a Kelvin bridge specially designed for the comparison of such resistances consisting essentially of two rows of 25 resistances and 20 ohms each were described.

ELECTRIC TRACTION NOTES

The annual general meeting of the Tramways & Light Railways Association was compressed this year into half a day in London, instead of the usual three days in the provinces. The programme contained three Papers, none of which, however, evoked very considerable discussion, and we therefore confine our notes on the proceedings to a brief reference to the one or two features which assumed most importance during the meeting. In the first place, the Council has had under consideration the very serious position in which tramway undertakings are finding themselves in regard to obtaining supplies of materials such as car wheels, axles, tyres, &c. The matter was referred to in a Paper by Mr. J. W. Dugdale, General Manager and Engineer of the Oldham Corporation Tramways, who mentioned the necessity for placing orders for tramcar tyres at prices 50 per cent. higher than those paid twelve months ago, and at the same time having to wait months for delivery. Mr. Dugdale suggested the appointment of a Purchasing Committee, which would deal with the question of obtaining supplies for all tramway undertakings, at any rate during the war. The Council have passed a resolution asking the Minister of Munitions to receive a deputation on the matter at an early date. Another matter which is exercising the managements of tramway undertakings, and which, in some managers' view, is even more important than obtaining supplies, is the gradual shrinkage in the labour available. Many tramway managers foreshadow serious curtailment of services and the probable stoppage of some routes altogether, unless something is done which will leave their employees free from further recruiting. So far as the technical staffs in the power stations and substations are concerned, the men employed by the Metropolitan Tramways, Ltd., and the London United Tramways, Ltd., have been allowed to enrol as munition makers, and their application forms are stamped "Public Utility Service," and the Minister of Munitions has expressed the opinion that such men are considered as much serving their country as if they were actually in a factory. No doubt this principle will be applied to all tramway undertakings. The difficulty, however, with the motormen and conductors is that even tramway managers cannot force themselves to the view that these can be regarded by any stretch of imagination as munition workers, although the Government has given instruction that tramway services for conveying munition workers to and from their work are to be maintained at all costs, and, where necessary, both day and night.

Another Paper read at the meeting was by Mr. A. V. Mason, General Manager of the South Metropolitan Electric Tramways & Lighting Co., which had the title "Glimpses into the Obvious," and dealt with a large number of minute details connected with tramway management, apart from the engineering aspect, which we do not propose to traverse here. He gave a list of thirty "bread-and-butter" tips, which no doubt will be read with interest by tramway managers, but they have no reference to engineering matters, notwithstanding their admitted importance to the proper conduct of a tramway undertaking.

The final Paper was by Mr. W. H. L. Watson, of Edison Accumulators, Ltd., and dealt with "Electric Battery Vehicles as Adjuncts to Tramways." In the main it added little to our knowledge of the use of battery vehicles, as it was discussed at the annual meeting of the I.M.E.A. about a month ago (ELECTRICAL ENGINEERING, June 24th, p. 273). Reference was, of course, made to the South Shields and York buses, and similar vehicles are now running at West Ham and Loughborough, but experience is too short to draw any conclusions. Another direction in connection with tramways in which battery vehicles are now being used is for tower waggons for the repair of overhead lines, and Ilford, Derby, and Belfast have testified to their satisfactory working. The same complaints were made in the brief discussion which followed the Paper as were made at the I.M.E.A. meeting, and also at the Institution of Municipal and County Engineers' annual meeting more recently, as to the high cost of all forms of battery-driven vehicles and their slow speeds. It was remarked, as a curiosity, that whereas a battery vehicle is able to maintain a high speed on a short, sharp hill, it is painfully slow on long gradients less severe. In this connection Mr. Watson mentioned that experiments have been carried out with a change-speed mechanism, but so far they have not been successful. At the same time, the real object of these experiments was not so much to increase the speed as to secure a lower current consumption on the hills.

ELECTRIC POWER IN A BAKERY

A MODERN bakery can only afford to employ the most efficient methods, and this has been recognised in the recent installation of electric drive in the Plantation Bakery of Messrs. J. and B. Stevenson in Glasgow. This firm had previously equipped their Cranstonhill Bakery with B.T.-H. electric motors (see ELECTRICAL ENGINEERING, Vol. X., p. 196, April 2nd, p. 197), and so successful were the results from this electrification that they determined to equip their Plantation Bakery in the same way. Power is obtained from the Glasgow Corporation. The firm has found that with the electric drive they have an increased output of superior quality, together with greater cleanliness and economy. No-

FIG. 1.—PIPE-VENTILATED MOTOR DRIVING AUTOMATIC MOULDING PLANT WITH AN OUTPUT OF 2,400 LOAVES PER HOUR.

where is a clean form of power more requisite than in a bakery, and electricity supplies the cleanest form of power possible. It is also important to remember, in this class of work, that with electric motors the expense for current is proportional to the work done, for while standing idle the motor does not consume any current, and when running consumes only sufficient current to do the work, and as it is as simple a matter to start or stop the motor as it is to turn the electric light off or on, there is no inducement to allow the motor to run idly, but to employ all the current usefully.

Fig. 1 shows a 12-h.p. B.T.-H. pipe-ventilated motor driving automatic moulding plant, comprising divider, hander-up, automatic prover, and Scotch moulding machine, having an output of 2,400 2-lb. loaves per hour. Fig. 2 shows a 25-h.p. B.T.-H. pipe-ventilated motor driving two kneading machines, automatic flour-sifters and weighing machines, comprising a three-sack installation. There is

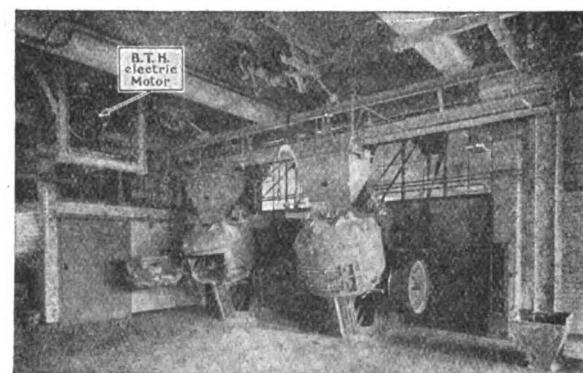

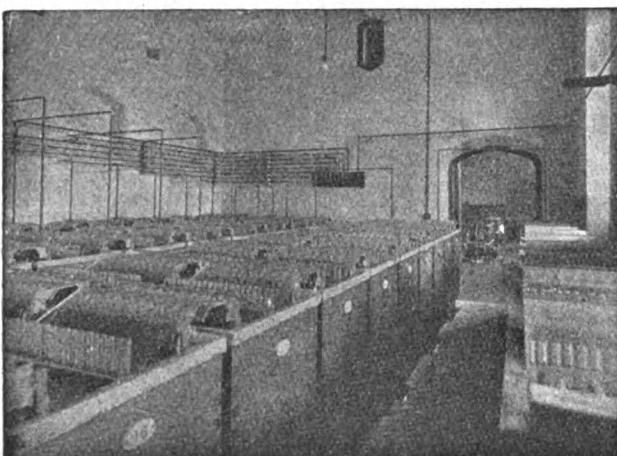

FIG. 2.—KNEADING MACHINE, FLOUR SIFTERS, AND WEIGHING MACHINE DRIVEN BY PIPE-VENTILATED MOTOR.

also an 18-h.p. pipe-ventilated motor driving stirring machine, flour-sifter, and automatic weighing machine. This use of pipe-ventilated motors is a special feature; they draw in air from the outside of the building, thereby avoiding the motors being clogged by working in a dust-laden atmosphere. We understand that the installation has proved thoroughly successful, so much so that repeat orders have been placed for electric motors. Attention should be called to the way in which limitations of space are met by suspending the larger motors from steel framework from the roof, thereby leaving the floor space entirely clear for production. The British Thomson-Houston Co., Ltd. (Rugby) supplied the motors for the above interesting installation, and other examples of motors supplied by them for driving bakers' machinery are found at Cranstonhill Bakery, and the Scottish Wholesale Co-operative Baking Society's Dalziel Bakery in Motherwell.

TUDOR ACCUMULATORS FOR COUNTRY-HOUSE LIGHTING

STONELEIGH ABBEY, KENILWORTH.

Battery of 56 cells, 1940 ampere-hours.
(Plant supplied by Midland Electric Light & Power Co., Ltd.)

SMALL BATTERIES from 35 AMP.-HOURS UPWARDS.

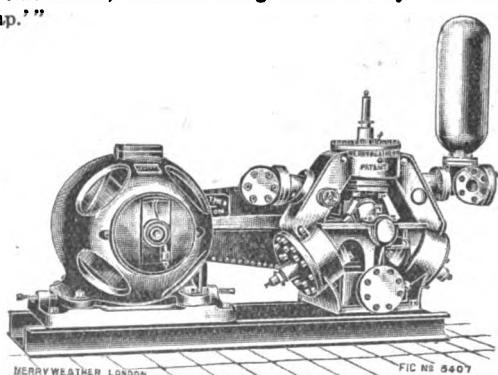

ASK FOR PRICE LIST of COMPLETE BATTERIES for
25, 50 and 100-volt INSTALLATIONS.

THE "HATFIELD" PUMP

Merryweather's Patents.

A Client writes:—"The 'Hatfield' Pumps at this Hotel are particularly successful, especially as regards their silent working. In many hotels one stops at, you can hear the hammer of the pumps vibrating through the whole building, which is very irritating to visitors. Many a comfortable night a man spends in his bed at this Hotel, without being disturbed by 'the thump of the pump.'"

MERRYWEATHER & SONS
Fire Engine Works, Greenwich, S.E., London.

A NEW ELECTRIC FIRE

A NEW pattern of electric fire, with a special form of built-up bar-heater, has been put on the market under the name of the "Qued" electric fire by Ikin & Eads, Ltd. (47-57 Marylebone Lane, W.), who now carry on the electric heating business started many years ago by Neville, Williams & Co. The construction of the heating element is shown in the figure. The body is composed of a series of special shaped moulded discs of a very carefully chosen quality of fire-clay strung on an iron spindle, clamped tight and prevented from turning by rods slipped through holes from the end. These discs form, when assembled, a core with a series of open slots half-way round, which contain

HEATING ELEMENT OF "QUEAD" FIRE.

the helically-wound nichrome resistance wire which is in a single length zig-zagging round the separating partitions. The wire is thus well supported, although perfectly free to expand. The ends are clamped to substantial terminal plates, and the whole element is simple, strong, and electrically sound. It is run at a bright red heat, and is usually made up in one-kilowatt units, any number of which can be mounted in a single case. We have seen some very artistic and serviceable designs of radiator equipped with these units, and with the whole wire and support glowing together a wonderful radiant effect is produced. These fires, which are remarkably reasonable in price, are to be seen in the firm's showrooms at the address given above.

CATALOGUES, PAMPHLETS, &c., RECEIVED

FANS.—Drake & Gorham, Ltd. (1 Felix Street, Westminster Bridge Road, S.E.), have issued a new list of electric fans of the "Phoenix" type, including desk and bracket fans of the swivel and trunnion pattern for continuous and for alternating current, as well as a small rigid desk fan, oscillating fans, ceiling fans, and porthole and box-blade exhaust fans.

STEAM, WATER, AND AIR-FLOW METERS.—A descriptive list from the British Thomson-Houston Co., Ltd. (Rugby), contains particulars of a series of instruments for the measurement of flow of steam, water, and air in pipes. These act on the principle of the Pitot tube, and employ a plug, with suitable orifices inserted in the pipe by which the velocity head is measured. A number of forms of meter are made, including a dial form direct-reading indicating instrument, as well as recording and integrating patterns. These are actuated by the movements of floats in the mercury contained in a U tube arrangement exposed to the differences of pressure due to the velocity head.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

SWITCHGEAR.—Particulars of a series of designs of A.C. cellular pattern switchboards are contained in a new illustrated leaflet from J. H. Holmes & Co. (Newcastle-on-Tyne). The gear is such that a board of any kind can be built up of self-contained panels with complete interlocking gear and all apparatus in iron cubicles.

POCKET LAMPS.—A folder from Haylock & Haslett (63 Queen Victoria Street, E.C.) gives prices of several patterns of electric torches, and calls special attention to a pocket lamp similar to and little larger than a fountain-pen.

TURBO-GENERATORS.—Two pamphlets from Greenwood & Batley, Ltd. (Albion Works, Armley Road, Leeds), give particulars of generating sets driven by high speed geared turbines of the de Laval type. In one of them a 300-kw. mixed pressure set at the Griff Colliery, near Nuneaton, is described.

THE "INSTALLATION NEWS."—The July issue of this little publication of Simplex Conduits, Ltd. (116 Charing Cross Road, W.C.), contains an article on the illumination of shop windows and of factories, as well as other interesting contributions and notes on Simplex novelties.

"EDISWAN ELECTRIC SERVICE."—The second issue of this magazine of the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex), has some interesting news regarding the latest extension of the Ediswan factories and showrooms, and describes some recently introduced pieces of apparatus, fittings, &c.

LEAD COVERING.—A leaflet from Sherard Cowper Coles (1 and 2 Old Pye Street) calls attention to a process of coating iron and steel surfaces with a protective welded-on covering of lead which should result in a surface of great utility for a number of industrial purposes.

STORAGE BATTERIES.—A pamphlet from the Chloride Electrical Storage Co., Ltd. (Clifton Junction, Manchester), gives illustrated particulars of the construction of the "Ironclad Exide" battery, which is extensively used for the propulsion of electric vehicles. The electrodes consist of a number of vertical pencils connected at the top and bottom to horizontal bars. Each vertical pencil contains a core surrounded by the active material, which is in turn enclosed by a hard rubber tube with horizontal slits, allowing of the access of the electrolyte. Ribs are provided to stiffen the tubes and to act as insulating spacers. The low internal resistance enables this form of battery to discharge at very high rates, and excellent records of life have been shown in actual road service.

VACUUM CLEANERS.—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.) have issued a new list of electric vacuum cleaners. This includes a powerful portable diaphragm pump machine as well as an apparatus on the bellows principle, and a number of self-contained sets in which the vacuum is produced by a high-speed rotary fan. The lists of accessories for each pattern of machine are very complete, and the list contains all that is required for selecting an outfit to meet any requirements.

METERS.—A catalogue from Thompson & Co. (48 Watling Street, E.C.) gives particulars of several forms of the "Rex" alternating-current induction-type meter of the latest design, which are manufactured in Geneva (Switzerland) by the Société Genevoise pour la construction d'instruments de physique et de mécanique, a firm which has carried on the manufacture of instruments for over sixty years.

BOILER ACCESSORIES.—A leaflet from the National Boiler & General Insurance Co., Ltd. (St. Mary's Parsonage, Manchester), gives particulars of the "National" patent circulator, which is an appliance for preventing external wasting of economiser pipes by raising the temperature of the water entering the economiser by contact with the heated outlet water.

TAR DISTILLING PLANT.—An illustrated pamphlet from the Power Gas Corporation, Ltd. (Stockton-on-Tees), calls attention to a self-contained tar distilling plant such as can deal with tar produced as a by-product from Mond gas producers, &c., to convert the tar into pitch and to recover the oils.

LARGE CAPACITY AUTOMATIC STOKERS

THE 16-retort Erith-Riley Stoker, as built by Erith's Engineering Co., Ltd., 70 Gracechurch Street, London, has the largest capacity of any stoker in use. Four of this size are in use in one plant. Its normal capacity is no less than four tons of coal hourly, and it has 50 per cent. overload capacity. Each stoker is applied to an undivided furnace of a single water-tube boiler, 25 feet wide. The capacity of this stoker is equal to that of a battery of eight large Lancashire boilers, occupying a site 100 feet wide. The use of such large-unit boilers is naturally confined to central electricity stations; but the entirely automatic working of the Erith-Riley Stoker permits unlimited unit capacity. The stoker is of the inclined underfeed type, with the fires kept continually sliced and the ash continuously discharged by reciprocating tuyeres and ash-pushers. The air for combustion is delivered direct to the tuyeres by a suitable fan, and both air and fuel automatically respond to load variations. Each stoker consists of a series of standardised and interchangeable retort-units; four boilers each with 4-retort stoker, or two boilers each with 8-retort stoker, will therefore give identical results to above-mentioned boiler with one 16-retort stoker. For mills, etc., using Lancashire boilers, the Erith stoker is employed, viz., each single-retort unit is applied to each internally-fired furnace; the capacity per retort remains the same, and the combustion is equally smokeless and efficient.

Electric Lighting Provisional Orders.—The Board of Trade had before it last year 31 applications under the Electric Lighting Acts for provisional orders, 20 of which were made by local authorities, and 11 by companies or persons. Of these, 25 were sanctioned, three were rejected, and in three cases the promoters decided not to proceed with the order. In one case only has the opposition been carried into the committee rooms at Westminster, and that is the case of the Southampton Order authorising the Corporation to supply in the parish of Bitterne. In that instance the Southampton Gas Co. asked for the Northumberland Clause, but failed in the House of Commons, and at the moment their opposition in the House of Lords has yet to be heard.

"BILLS"

WE reproduce here an amusing postcard design which has been produced by the Edison & Swan United Electric Light Co., Ltd., Ponders End, Middlesex. This is printed in three colours, and the reverse side is overprinted, leaving

sufficient room for correspondence. We hope that the German "Bills" will be as effectually "kept down" by present events as those of consumers undoubtedly are by the use of these famous drawn-wire lamps.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Ashton-under-Lyne.—Negotiations are in progress with regard to giving a supply in bulk to the Hurst District Council.

Australia.—The Sydney Council requires a two years' supply of A.C. and D.C. motors. Preference will be given to British manufacturers. Tenders to the Town Clerk, Sydney, by Sept. 13th. This information is only of value to firms having agents in the Commonwealth who can be instructed by cable.

Aylesbury.—New cable at an estimated cost of £400 is required.

Barnsley.—The recent application of the Corporation for £21,850 for extensions to plant, mains, &c., has been reduced to £15,000 by the elimination of certain items. At the local inquiry last week the Town Clerk said that the existing plant is totally unable to meet further demands upon it, and in the case of one munitions factory the Department was only able to supply one-quarter of the power required. The extension scheme was abandoned a short time ago on account of the war, but the demands upon the plant now are such that it is imperative the extensions should be carried out.

Bristol.—One 6,000-kw. three-phase turbo-alternator, with condensing plant. Chief Engineer. August 23rd. (See an advertisement on another page.)

Keighley.—Switchgear is required in connection with a new 5,000 kw. turbo-alternator at an estimated cost of £3,225.

London: Bethnal Green.—Having regard to the special circumstances attaching to the Council's electricity supply

scheme, the L.C.C. a short time ago intimated to the Treasury that it should be allowed to proceed. The Treasury has now given the required permission for the borrowing of the necessary sum, viz., £22,450, and of £2,000 for sub-station buildings.

Poplar.—By arrangement with the L.C.C., the Borough Council is taking on loan £8,173 from certain other funds for electrical extensions.

Rotherham.—H.T. cable, trolley wire, and meters. Borough Electrical Engineer, July 24th.

Swinton.—Extensions are to be carried out to the electrical equipment of Matthews & Yates' works.

Wiring

Bradford.—Five houses, Arncilffe Terrace and Woodhead Road. P. T. Cowling, 93 Horton Road.

Treforest.—The arrangement of wiring at Girls' School. Architect, B. J. Day, 8 Park Place, Cardiff.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Portsmouth.—Business premises, King's Road, Southsea. Architect, C. W. Bevis, Elm Grove Chambers, Yarborough Road.

Rhymney.—Isolation Hospital. Clerk.

Swindon.—Sanatorium. County Surveyor, Trowbridge.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Grangemouth.—A contract for a twelvemonths' supply of Tantalum and Wotan lamps has been placed with Siemens Bros.' Dynamo Works.

Heywood.—The following tenders have been accepted:—600 kw. booster, British Westinghouse Co.; reversible battery booster, Phoenix Dynamo Manufacturing Co.; D.C. switchboard, Bertram Thomas; E.H.T. overhead cable, British Insulated & Helsby Cables.

Keighley.—The Electricity Committee recommend the acceptance of a tender by Willans & Robinson for a 5,000 kw. turbo-alternator at £15,875, subject to arrangements being made for deferred payments.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. Geo. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £90 to £91 (last week, £93 to £94).

Advance in Prices.—The Sterling Telephone & Electric Co., Ltd. (210-212 Tottenham Court Road, W.) announce a further 15 per cent. advance, making a total of 25 per cent. increase of their list prices, with the exception of wood bell-pushes, which are only advanced 10 per cent., and certain other prices which are withdrawn.

Bankruptcy.—Herbert Page, trading as Smeeton & Page, Electrical Engineer, 63 Queen Victoria Street, E.C., has been adjudicated bankrupt. The first meeting of creditors is to be held to-day at 11 a.m., at Bankruptcy Buildings, Carey Street, and the public examination is at 11 a.m. on Sept. 7th at the same place.

APPOINTMENTS AND PERSONAL NOTES

Mr. G. G. L. Preece, who for some years has been in charge of the Manchester office of Messrs. Bruce Peebles &

Co., Ltd., has accepted a commission in the Lancashire Fusiliers. During his absence, Mr. E. W. Browne, the Company's representative in Birmingham, will act as manager in Manchester.

Mr. A. J. Howard, Borough Electrical Engineer at Taunton, has been presented with a silver salver by the members and officials of the Town Council on the occasion of his wedding.

Mr. J. B. Sparks has rejoined Dr. Parshall, and is now representing him on important electrical engineering construction work in Spain.

LOCAL NOTES

Carlisle: *Electricity Accounts.*—There was a loss of £76 on the past year's working of the electricity undertaking. The exceptional conditions, however, accounted for this result, as not only were various reductions made in the charges, but the revenue from public lighting was £1,000 less and the coal cost was very much higher than in the previous year. There was also the cost of war bonuses and allowances to men on active service. With the exception of one year, the total costs were the lowest on record, the difference being due to the high cost of coal.

Glasgow: *High Coal Cost.*—It is stated that the Glasgow Electricity and Gas Departments will pay £250,000 extra for coal during the coming year. The Electricity Department has increased its rates by 15 per cent., and there is a hint that further increases may be necessary.

London: *St. Pancras: War Loan.*—The Electricity Committee has invested £10,000 from Reserve Fund in the War Loan.

Plant Extension.—In connection with the scheme for extending the King's Road Electricity Works at an estimated cost of £49,818, the Council has been approached by the Treasury, through the L.C.C., as to the possibility of postponing this. The Electricity Committee report that quite apart from the fact that two new boilers have already been contracted for, it will be necessary to proceed with these in order to be able to supply factories working on Government orders. The original scheme included four boilers, but the installation of the second two is to be postponed. A new 5,000 kw. turbo-alternator is in process of construction as part of the scheme. Expenditure to the extent of £25,053 is therefore to be postponed.

Mansfield: *Profits and Relief of Rates.*—The Electricity Committee has voted £600 out of last year's electricity profits to the relief of rates.

Oldham: *Mains Accident.*—There was an unfortunate accident on the mains recently, due to a rather curious cause. When the cables were laid about 20 years ago they were fixed in direct contact with a gas main, and a fault on the cable was sufficient to burn a hole in the gas main. The gas was naturally ignited, and a large blaze was emitted from the street-boxes. There was, however, no actual explosion.

Southampton: *Northumberland Clause Again.*—We mentioned on p. 282 of our issue of June 24th that the Southampton Gas Co. had been refused the "Northumberland" clause by a House of Commons Committee in respect of an extension of the Southampton electric supply area to include a small parish called Bitterne, the total capital expenditure upon which was estimated to be £400. The Gas Co., however, renewed its application for the clause when the Provisional Order in question came before the House of Lords Committee. Sir John Snell again gave evidence, but eventually the Committee decided to grant the clause in respect of the new extension only. The Gas Co. asked that the clause should be applied to the whole of Southampton, but the Corporation informed the Committee that if that were done the extension scheme would be dropped.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

St. James's & Pall Mall Electric Light Co.—Interim dividends at the rate of 7 per cent. per annum on both preference and ordinary shares for the June half-year are to be paid.

SUMMARY

MR. T. ROLES has contributed a long written reply to the discussion on the paper by him and Mr. Blackman on the Point-Five tariff, read at the I.M.E.A. meeting (p. 320).

SOME notes are given on work recently accomplished and now in hand by the Engineering Standards Committee (p. 320).

THE Government Bill for limiting the price of coal has passed the Committee stage. In connection with existing contracts, which are excluded from the Bill, a promise has been given to deal in some way with any contracts entered into for next winter by Corporations and public utility companies (p. 321).

THE regulation of motor generators for plating work is dealt with in our Questions and Answers columns (p. 321).

AMONG the subjects of specifications published at the Patent Office last Thursday were A.C. motor control, microphones, heating circuits, telephony, and search-light carbons. The Board of Trade has granted a licence under an enemy-owned patent for sparking plugs (p. 322).

CONSIDERABLE interest attaches to the statement made at the annual meeting of Marconi's Wireless Telegraph Co. by the Managing Director as to State-aided competition from Germany and the position with regard to the Imperial wireless scheme (p. 322).

A CONFERENCE is proposed between the L.C.C. and

other traction undertakings with a view to diminishing competition and releasing more men for active service (p. 323).

AN illustrated article deals with the use of condensers for surge protection (p. 323).

THE process of making glass-house pots in the Ediswan Works is described in an illustrated article (p. 324).

A CORRESPONDENT calls attention to the dangers of dimming bare incandescent lamps by wrapping tissue paper round them (p. 325).

THE Treasury has refused to sanction the full capital expenditure proposed on the Battersea, Hammersmith and Fulham linking up scheme.—Loans have been sanctioned at Woolwich for mains and house wiring in connection with a munitions workers housing scheme, and for linking up with the South Metropolitan Electric Light and Power Co.'s power house.—Switchgear is required by the L.C.C.; substation plant at Stoke on Trent.—New generating plant (£91,417) at Coventry and Bury (£7,560); cables, transformers and switchgear at Walsall; cable at Rochdale; and mains, rotary converters, services etc., at York (p. 325).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING AUGUST 7TH, 1915.
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday, Wednesday, and Friday:—Drills 6.30 and 7.30.

(There will be no drill on Monday, August 2nd.)

Applications for Enrolment:—All applications for enrolment should be sent to the Commandant, Marconi House, Strand, from whom all particulars can be obtained.

E. G. FLEMING.
(Company Commander and Acting Adjutant.)

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

Trade Exhibitions after the War.—A comprehensive scheme is on foot for erecting a large exhibition building or "Palace of Industry" for the holding of trade exhibitions in the London area, and in particular for a large industrial fair in the spring of 1917. Already a site of 44 acres has been acquired at Willesden Green alongside the Metropolitan Railway, within 7 mins. journey from Baker Street, and a building of 500,000 sq. ft. area will shortly be commenced. It is proposed that the profits of the exhibition be distributed among the firms participating in proportion to the space occupied by them, and the management is anxious to get into touch with the Trade Associations and Societies in the country which are not already represented on the Advisory Council. Communications should be addressed to Mr. W. Glass, Secretary, Industries of the Empire Fair, Lincoln House, High Holborn, W.C.

THE PRACTICAL RESULT OF THE POINT-FIVE TARIFF

WE have received from Mr. T. Roles (City Electrical Engineer, Bradford) a copy of his full reply to the discussion on the Paper by him and Mr. A. S. Blackman on the point-five tariff read at the meeting of the Incorporated Municipal Electrical Association in London on June 17th (see ELECTRICAL ENGINEERING, June 24th, p. 267).

Mr. Roles writes that the majority of the speakers seem to be under the impression that the rateable value tariff and the point-five tariff are synonymous, whereas, as a matter of fact, a number of point-five tariffs are in no way based on the rateable value system of charging. "The Point-Fives" Association as a body, he continues, holds the opinion that no great headway can be made in the supply of electricity for heating, cooking, and other domestic purposes, apart from lighting, at any price exceeding ½d. per unit, in districts in which gas is sold at 2s. 6d. or under per thousand cubic feet. In Bradford and Sunderland the fixed charge arrived at on a rateable value basis has been so calculated that, plus a charge of ½d. per unit for current used for lighting purposes as registered by meter, it is on the average equal to the cost of lighting a house moderately well throughout at between 3½d. and 4d. per unit. It follows, therefore, that on the average all units sold for heating and cooking purposes, and any increase of illumination above the ordinary, are obtained by the consumer at a flat rate of ½d. No member of "The Point-Fives" Association has claimed to supply electricity for all domestic purposes at a flat rate of ½d. per unit or less. The majority of the members, however, do claim to be selling electricity for heating and cooking purposes at ½d. per unit, whether their tariff is based on the rateable value system or on a flat rate for lighting and a separate flat rate for heating and cooking.

He had already given figures in the Paper which made it clear that, in the case of Bradford at any rate, there is no foundation for the suggestion that a point-five tariff under the rateable value system is a means of deluding the undertaking's consumers into believing that they are getting a substantial reduction and current for heating and cooking purposes at a low rate, whereas in reality they are not. With regard to the class of consumers attracted by the point-five tariff, he states that of the 566 point-five consumers supplied in Bradford during 1914, well over 50 per cent. resided in premises having rateable values of £30 or less. Mention had been made of the large number of gas cookers and fires in use in Hereford; the fear was expressed that if electricity was supplied at a low rate for heating and cooking purposes the Gas Department would suffer, and that, taking the two Departments together, the result would be a net loss to the Corporation. In Bradford it was found that the persons who adopted electric heating and cooking were not at the present time using gas, but coal, for these purposes, as they had a rooted objection to the use of gas for any purpose whatever.

The statement made that St. Marylebone is the only point-five undertaking which has not adopted the rateable value system, but has the kilowatt maximum demand system in operation, is totally incorrect. Both Poplar and West Ham are also working on the kilowatt demand system, and Southampton, Luton, and Wakefield have adopted a flat rate of ½d. per unit for heating and cooking purposes. Mr. Wordingham appeared to be under the delusion that the rateable value system and the point-five tariff are one and the same thing, as he states that "The Point-Fives" Association have re-discovered the "Hopkinson" system and are bringing it forward and advertising it for all it is worth. The reply to this statement is that neither the Association nor any of its members takes credit for the introduction of the rateable value system, but some members have applied the system—which had already proved its merits—to their own needs. In reply to Mr. Wordingham's scepticism in the possibilities of electric water heating, Mr. Roles stated as a fact that a number of electric water-heating installations are at present in use, are giving satisfaction, and are proving economical. With regard to Mr. Lackie's remark that before fixing the Glasgow tariff his main endeavour had been to see that the revenue per house was increased and not diminished, this was also the endeavour of Mr. Roles, providing that the increase was due to the installation of additional lights or of heating and cooking apparatus, and figures given in the Paper showed that the endeavour had met with success.

Mr. Long had asked how a point-five tariff could be justified in the case of towns in which the cost of coal per unit is in the neighbourhood of ½d. This question, says Mr. Roles, can only be satisfactorily answered by the engineers of the towns concerned. When fixing the amount to be allocated to standing and running costs under any tariff, it is usual for at least 25 per cent. of the coal costs, and considerably higher percentages of other items making up the works costs, to be debited to standing costs. If only 25 per cent. is taken off the figures given with regard to the average cost of coal per unit in the towns mentioned, the charge of ½d. per unit will compare

much better with the coal costs. It must also be remembered that the coal costs quoted are average costs, and that the cost of generating units during the hours of light load is very much higher than during the heavy load periods. In works supplying residential districts the number of hours of light load is very high compared with the number of hours during which a moderately good load is sustained. If, therefore, by selling electricity at a cheap rate for heating and cooking purposes, a good day load can be obtained, not only is the cost of generation reduced during the hours of light load, but the average figures per unit in respect of each item of works costs may also be appreciably lowered.

THE ENGINEERING STANDARDS COMMITTEE

THE first annual meeting since its reorganisation of the Sectional Electrical Committee, of which Sir John Snell is Chairman, was recently held to approve such work as was completed during the session and to receive the reports of the work in progress. The following reports, which have been transmitted to the Main Committee for ratification, will shortly be available:—British Standardisation Rules for Electrical Machinery; British Standard Specification for Electricity Meters; British Standard Specification for Charging Plug and Socket for Vehicles propelled by electric secondary batteries; British Standard Specification for Wall Plugs and Sockets, five-ampere, two-pin, without earthing device.

The Sub-Committee on electric power cables, of which Mr. C. P. Sparks is Chairman, has under consideration the revision of the report on copper conductors. The Sub-Committee on electric lamps will, in co-operation with the Tungsten Lamp Association, in the early autumn, consider the drafting of a standard specification for tungsten lamps, and the question of miner's electric lamps will also receive attention. The Sub-Committee on electrical accessories, of which Mr. C. H. Wordingham is Chairman, has several panels at work, and it is hoped that recommendations will soon be forthcoming in regard to motor-starters, heating and cooking apparatus, and fuses, as well as other electrical fittings. A panel has also been formed to revise the Standard Specification for ammeters and voltmeters, and on this panel the British Electrical and Allied Manufacturers' Association will be represented by Mr. E. B. Vignoles and Mr. Patrick Hamilton. The Sub-Committee on electrical symbols, presided over by Dr. A. Russell, has appointed two panels, one to draw up a list of graphical symbols for use in installation and power work, and the other to deal with telegraph and wireless symbols. The question of standards for distributing pressures for new systems, which has been brought forward by Mr. C. H. Merz, is to occupy the attention of a Sub-Committee under the Chairmanship of Dr. R. T. Glazebrook, upon which all interests will be represented. As an indication of the activities of the Committee, it may be mentioned that during the past year more than ninety meetings have been held, and from the above notes it will be appreciated that the electrical section is engaged on work of great importance to the industry at large.

Obituary.—We regret to record the death on July 16th, near Glasgow, of Mr. Henry A. Mavor, of the firm of Mavor & Coulson. Mr. Mavor, who was born in 1858, has long been well known in electrical circles, and in the early days did energetic pioneering work in the introduction of electric lighting in Glasgow. Since 1883 he has been a partner in the firm originally founded as Muir & Mavor. Among other branches of electrical engineering he turned his attention particularly to electrical work in mines, and carried out the earliest installations of the kind in Scotland. During later years he had interested himself in the problem of electric marine propulsion, and worked out more than one system of control in this connection. Two vessels have already been equipped with electrical transmission gear under his direction. Mr. Mavor had been in poor health for some time, and leaves three sons (all of whom are now on active service with the Army) and a widow.

A Handbook of Halifax.—Messrs. Sells, Ltd., have published an illustrated industrial handbook of Halifax under the auspices of the local Chambers of Commerce and Trade, which contains interesting particulars of this important commercial and industrial centre. Its aim is to show manufacturers and merchants at home and abroad the vast range of work produced from this centre, which is now as well known for its machinery as its woollens, and also to attract to this area those contemplating setting up new works by demonstrating the advantages of the town's position.

COAL SUPPLIES

AS indicated on p. 311 of our last issue, there is considerable feeling among certain Members of Parliament that the Government Bill for limiting the price of coal will fail completely to meet the object which those who framed it had in view. The limitation of the Bill does not apply to contracts already made, and it is said that a majority of the large electricity and gas undertakings, for instance, have already entered into contracts at a higher price than the maximum excess of four shillings allowed in the Bill.

The opponents of the Bill from this point of view made the most of their case during the Committee proceedings on Thursday, but the Government refused to regard the point as serious. The President of the Board of Trade contended that although a few public utility undertakings may have entered into contracts already, a large majority have not. Special mention, however, was made of the Glasgow Corporation, which has purchased large stocks of coal for its electricity undertaking at high prices, and in this connection the Government offered to see what steps could be taken to bring such special cases of local authorities and public utility companies within the provisions of the Bill. The necessary amendment was introduced into the Bill on Tuesday. It provides that any contract affecting local authorities, electricity, gas, or water undertakings, entered into since April 1st shall be subject to the limitation of price imposed by the Bill upon contracts entered into since the date of passing of the Act.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

QUESTION No. 1,453.

Is it practicable, and are there any circumstances in which it is advantageous, to take the excitation circuit of a 4-pole dynamo from one pair of brush arms while the other pair is used only for the load?

(Replies must be received not later than first post, Thursday, August 5th.)

ANSWERS TO No. 1,551.

A motor-generator for electroplating work is required to run off a 3-phase supply, and is to give out a current of about 8,000 amperes at a voltage variable between 4 and 8. Is it possible to obtain such a variation by the ordinary method of shunt regulation if the machine is self-excited, or is it better or necessary to arrange the fields for separate excitation? Could the variation in volts be satisfactorily accomplished by regulation on the motor side? What are the advantages or disadvantages of using carbon brushes as against copper gauze brushes on a generator of this size?

"W. M."

The first award (10s.) is made to "H." for the following reply:

The voltage variation required in the question could be obtained from a self-excited dynamo by means of shunt regulation; but the result would not be satisfactory, firstly, because at the lower voltage the machine would be working with a weak field, causing the voltage to be unstable—small fluctuations in the speed of the motor or in the resistance of the external circuit giving rise to large variations in the terminal voltage; secondly, the shunt current for the dynamo under consideration would probably be about 200 amperes at

the maximum voltage, and a regulator suitable for such a heavy current would be expensive to construct. For the voltage regulation required in the question, separate excitation is the only satisfactory solution. It may be mentioned that for sparkless commutation with a variable-voltage dynamo, interpoles must be fitted, otherwise armature reaction causes trouble when the main field is weak. As regards the suggestion of obtaining the regulation from the motor side, this is not economically possible unless a three-phase commutator motor is installed, since the speed variation required can only be obtained from an induction motor by inserting resistance in the rotor circuit—a most wasteful method. The high cost of the commutator motor, moreover, generally prohibits its adoption. If a separate continuous-current supply is not available, it will be necessary to put in a small exciter either directly coupled to or belt-driven from the motor-generator set. Any desired voltage variation can then be obtained economically and without any difficulty. For low-voltage dynamos it is the universal practice to employ copper gauze brushes, of which there are several excellent patterns on the market. The advantages of gauze brushes over carbon ones are:—(a) They can be worked at a much higher current density, and so require less area of contact, with the result that the brush friction loss is greatly decreased and the commutator can be made much shorter; (b) the voltage drop between gauze brushes and the commutator is only a small fraction of that between carbon brushes and the commutator, so that the loss due to contact resistance is correspondingly diminished; (c) the advantage of carbon brushes in improving the commutation is of little consequence in a case of this kind, where the reactance voltage is generally very low.

The second award (5s.) is given to "P. W. S." who writes as follows:—

To attempt to make a machine of this sort self-exciting and insert a regulating resistance in series with the field winding would result in the use of very cumbersome apparatus, as the field winding of such a machine must necessarily consist of heavy cable and take a large current in order to get the required number of ampere turns. A much simpler method would be to have a separately excited field winding, wound for a fairly high voltage, say 100; a light resistance could then be used with a large number of studs, the number depending upon the degree of fineness in variation of voltage required. As the amount of variation in voltage is so large, namely, 50 per cent., and this would mean approximately the same variation in speed with a fixed field resistance, it would hardly be wise to attempt to get it by altering the speed of the polyphase motor, as these do not lend themselves readily to efficient speed variation. The simplest method of altering the motor speed would be to insert a variable resistance in the rotor circuit, but this would mean a large waste of power. Copper gauze brushes are nearly always used on electro-plating machines on account of the much smaller commutation required. To collect 8,000 amps. with carbon brushes would require a commutator whose size would be out of all proportion to that of the machine, particularly if the machine has few poles. The only advantage of carbon brushes would be less tendency to spark and a longer life for the commutator.

Diesel Engines.—At a recent meeting of the Diesel Engine Users' Association, Mr. G. E. Windeler (chief engineer to Mirrless, Bickerton & Day, Ltd.) read a short Paper on the causes of cracking and seizing of pistons in Diesel engines. He expressed the opinion that the major portion of the defects that had arisen on cylinder covers and pistons were due to serious deposits formed in the water spaces of the cylinder covers and on the cylinder liners not during the time the engine was working, but after the engine was shut down. The piston, cylinder cover, valves, &c., have a large number of heat units stored in them, and when the engine is shut down these heat units are absorbed by the water which remains in the jacket, the quantity of which is comparatively small, and a very considerable rise in temperature takes place; in fact, sufficiently high in the majority of cases to throw down the salts which were held in solution in the water. Where the circulating water is known to be of a considerable hardness, it should run through the water spaces for some time after the engine is shut down. He went into various matters connected with piston design, and said that seizures of pistons were also invariably due to heating of the piston pin and its bearing, and take place almost immediately after starting up. When an engine has been set to work and shut down, the heat stored in the piston body is thrown down and tends to evaporate the oil in the top end bearing, with the result that when the engine starts up again this particular bearing is not amply supplied with lubricating oil.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 22nd, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

683/14. **Motor Control.** J. L. ROUTIN. Means for collectively controlling a number of A.C. repulsion motors required to be run at equal speeds, in which the rotors of all the motors are provided with slip-rings electrically connected together to couple the machines, so that they must run in step with one another. (One figure.)

7,922/14. **Microphones.** A. F. SYKES and S. FORD. A microphone in which the sound waves act upon and control the variation in the amount of a conductivity changing substance added to a stream of liquid passing between two electrodes, and thus causes variations in the resistance of the circuit. (Eight figures.)

8,280/14. **Supply Circuits.** R. ARNO. A method of rendering circuits intended for the supply of heating apparatus only unavailable for lighting purposes by causing periodic momentary interruptions by an automatic thermal or other switch. (Four figures.)

8,794/14. **Telephony.** P. L. M. DRUMAUX. Reciprocal connections for two telephone lines connected with a relay for annulling or impairing the tendency to produce disturbing oscillations, characterised in that the relay is connected with the telephone lines by the interposition of artificial lines having inductance and capacity with comparatively small resistance and leakage, and being tuned and calculated in such a manner that the telephone currents propagate in an undulating manner with comparatively low frequency, small damping effect, and small distortion. One non-reflecting translator can be inserted between each of the artificial lines and the main line. (Two figures.)

15,485/14. **Search-light Carbons.** PLANIWERKE A.G. FÜR KOHLENFABRIKATION. The negative carbon is kept of very small dimensions relatively to the current it has to carry by being made of a mixture of carbon and about 40 per cent. of graphite.

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: B.T.-H. Co. (G.E. Co., U.S.A.) [Distributing system] 18,288/14.

DYNAMOS, MOTORS AND TRANSFORMERS: SCOTT [Armature windings] 16,093/14; SIEMENS BROS. DYNAMO WORKS, LTD., and KIEFFER [Cooling dynamos] 16,979/14; BURDEN (Siemens Schuckertwerke Ges.) [Laminated slot keys] 24,078/14; SCOTT [Dynamos and motors] 6,618/15.

BALL [Electric heating element] 20,286/14; VARVEL [Electric water heater] 23,293/14.

INCANDESCENT LAMPS: GLADITZ [Incandescent lamps] 9,110/14.

INSTRUMENTS AND METERS: HATFIELD and CHAMBERLAIN & HOOKHAM, LTD. [Electrolytic meters] 26,899/13; A. E. G. [Induction meters] 11,844/14.

SWITCHGEAR, FUSES AND FITTINGS: JESSEN [Switches] 4,447/14; C. A. SHAEFFER [Lampholders] 8,806/14; WILSON and HARLOW [Motor starters] 15,939/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Circuit breakers] 19,587/14; LIVERSIDGE and PENNSYLVANIA APPLIANCE CO. [Fuses] 131/15.

TELEPHONY AND TELEGRAPHY: SIEMENS BROS. & CO., LAIDLAW and GRINSTED [Telephone circuits] 26,905/13; GOLDSCHMIDT [Spark gaps] 2,214/14; POLYPHOS ELECKTRIZITÄTS GES. [Production of electric waves] 4,664/14; SIEMENS & HALSKE A.G. [Telephone circuits] 8,800, 9,103 and 9,105/14; MARKS (International Quadruplex Co.) [Telegraphy] 16,342/14; STERLING TELEPHONE & ELECTRIC CO. (Telephon Fabrik A.G. vorn. J. Berliner) [Relays and indicators] 16,418/14; EASTERN TELEGRAPH CO. and DAVIES [Relays] 16,471/14; HUGHES and COOPER [Telephone systems] 16,712/14; ZIERAU [Attachments for telephones] 18,607/14; GRINSTED [Telephone circuits] 821/15.

TRACTION: LAUTENBACHER [Trolley wires] 25,951/13; CEDES ELECTRIC TRACTION, LTD. and BOWEN [Trolley-wire junctions] 15,946/14; DOUGLAS and HODGSON [Staff exchangers] 19,441/14; HUE [Signalling apparatus] 19,950/14; HENSHER [Automatic signalling] 22,109/14; R. BOSCH [Car lighting] 5,184/15.

MISCELLANEOUS: H. ARON ELEKTRICITÄTSZÄHLERFABRIK [Electric clocks] 26,631/13; JAKOWLEW [Electric massage apparatus]

2,290/14; SMITH [Signalling in mines] 8,305/14; MARKS (Soc. Gallot & Cie.) [Medical magneto machines] 9,278/14; GODFREY [Electro-mechanical selectors] 9,718/14; SCHOLZ [Carbon electrodes for batteries] 10,171/14; STERLING TELEPHONE & ELECTRIC CO. and BELL (Telephon Fabrik A.G.) [Mine signalling] 13,062/14; BURT [Controlling race starting barriers] 16,315/14; STERLING TELEPHONE & ELECTRIC CO., BELL and DUNGEY [Mine signalling] 18,661/14; JOHN DAVIS & SON and DAVIS [Magnetic lock for miners' lamps] 21,046/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

DYNAMOS, MOTORS, &c.: MASCHINENFABRIK OERLIKON [Stator casings] 8,417/15.

TELEGRAPHY AND TELEPHONY: AUTOMATIC TELEPHONE MANUFACTURING CO., LTD. [Telephone systems] 9,396/15.

Applications to Avoid or Suspend Patents

28,412/12. **SPARKING PLUGS.** A. RUPRECHT. The Board of Trade has granted a licence under this patent on the application of H. W. Van Raden (trading as Davies and Walker). The specification describes a method of constructing sparking plugs with a split inner sleeve which keeps the porcelain tight. The following are the more important Patents that have become void through non-payment of renewal fees.

DISTRIBUTING SYSTEMS, CABLES AND WIRES, INSULATING MATERIALS, &c.: W. A. T. MÜLLER [Distributing system] 7,595/09.

DYNAMOS, MOTORS AND TRANSFORMERS: H. C. PEAKE and J. R. ENGLAND [Coal-cutter motors] 7,980/02; W. L. EMMET [Electric transmission for marine drive] 7,829/07; R. D. MERSHON [Incorporation of condensers into armature windings for improvement of power factor] 8,183/07; ATELIERS B.T.-H. (Paris) [Prevention of sparking in single-phase motors] 7,621/08; J. P. HALL [Ventilation of dynamos and motors] 7,854/08.

ELectrochemistry and Electrometallurgy: E. STASSANO [Electric arc furnaces] 8,288/02.

TRACTION: G. WESTINGHOUSE [Electro-pneumatic train control] 8,256/03; E. C. KETCHUM [Steam turbine locomotive with electric transmission] 7,750/08; A. SPENCER [Train lighting] 8,165/09.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The proceedings at the annual meeting of Marconi's Wireless Telegraph Co. on Monday were more than usually interesting by reason of a statement by the Managing Director as to the difficulties which the Company has had to encounter from German competition. Mr. G. Marconi, the Chairman of the Company, who is now a lieutenant in the mounted section of the Italian Royal Engineers, presided, he being in this country at the moment on Italian Government business. In placing the report and accounts (given in our last issue) before the shareholders, the Chairman mentioned that for the moment the Company's work in many parts of the world has come to a standstill owing to wireless telegraph apparatus being contraband. On the other hand, the factory is fully occupied in carrying out important orders both at home and abroad in consequence of the war. Since last year important developments in wireless telegraphy had taken place, and the Company had applied for several new patents, information concerning which, however, could not be given at the moment. Generally speaking, all the affiliated companies had shown satisfactory progress during the past year, and the high-power stations at San Francisco and Hawaii have been completed, the Company awaiting daily information as to the opening of a through service to Japan. The Chairman concluded with a reference to the work which the Company is doing for the British Government, and without entering into details said that more than one letter of appreciation from the Lords Commissioners of the Admiralty had been received in respect of this work. At the same time he paid a great tribute to the work of Mr. Godfrey C. Isaacs, the Managing Director of the Company, since his association with it in 1910. Mr. Godfrey Isaacs then addressed the shareholders at some length, and went into details of the position of the Company

in 1910 and its progress since. At that time, he said, the Company had practically no cash resources and no credit. Indeed, within a few weeks of his joining the Company he had to draw a cheque on his own banking account to pay the salaries due for the preceding month. To-day the Company had a capital of £1 million sterling, and was in a very sound financial position. The reasons for the lack of prosperity in the early days of the Company were, he said, due to the fact that immediately Mr. Marconi started the Company he was imitated in Germany, where a big German company was created, practically by the German Government. It was directed by some of the most eminent and able commercial men in Germany, and had the further great advantage of the financial aid of some of the principal German banks, whilst finally it had a very large subsidy from the German Government. This company created powerful agencies in practically every country in the world with the exception of Italy, France, and Great Britain. Not only had the English Company to contend with German agents, but also with German Ambassadors. The position was found to be so impossible that he made a direct appeal to Sir Edward Grey, and from that time forward the support of British Ministers abroad was obtainable in the Company's different negotiations with foreign Governments. From then the Company commenced to make substantial progress until it had reached undoubtedly the preponderating position throughout the world. Then came the suggestion of the Imperial wireless scheme, by which high-power stations were to be erected at the Company's expense in all British possessions, to be worked by the Company during peace, and handed over to the Government in the event of war. Difficulties arose in Parliament, however, and eventually the later Government scheme came into being. Meanwhile, the German Government, without discussing the matter publicly at all, began to build a chain of wireless stations in all German colonies. He was informed that the price paid for each of these stations was three times the price which the Marconi Co. had asked of the British Government, whilst there was a subsidy far larger than anything contemplated by the Marconi Co., which was to be paid not for eighteen years, as in our case, but twenty-five years. This scheme cost the German Government two millions sterling, and it might be thought to have been a very bad investment. Close investigation, however, proved this not to be the case, for at 5 o'clock on the afternoon of August 4th last year (the British ultimatum to Germany expired at midnight on the same day) the German Government sent out from all its wireless stations a message to this effect: "War declared upon England; make as quickly as you can for a neutral port." By that message Germany contrived to save the greater part of its mercantile marine. Even had it only saved one of its big ships of the *Vaterland* class, it would have paid for the whole cost of the wireless stations; but it was, of course, well known that this message did considerably more than that.

ELECTRIC TRACTION NOTES

It is proposed that a conference between the London County Council Tramways Department and the omnibus companies in London should be held under the Chairmanship of a representative of the Local Government Board to consider to what extent agreements can be arrived at to eliminate competing services in order to release more men for the Forces.

The scheme for the conversion of the capital of the British Electric Traction Co., which was temporarily put on one side last year owing to the war, was adopted at an extraordinary general meeting on Friday. Since it was last placed before the shareholders there have been one or two modifications, and it now provides for the reduction of the present total capital of £2,947,380 by £908,872, and to divide the capital thus reduced into 6 per cent. cumulative participating preference stock and ordinary stock.

The Bill promoted by the Underground Electric Railways Co. of London for the purpose of bringing about closer co-operation in the working of the various electric railway companies in London in which it is interested is now unopposed in Parliament. As we have already reported in our columns, opposition was offered by the London County Council, but the promoters have gradually met the points raised, and the Bill is now considerably modified in the direction of it not being possible under it to complicate the actual position of each Company individually.

SURGE PROTECTION

THE subject of protection of alternating-current systems from voltage surges is very fully treated in new Bulletin which has just been issued by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.). The cause and nature of such surges are discussed, and after a brief discussion of the capabilities and limitations of the horn, aluminium, and multi-gap patterns of arrester, the claims of condenser protective gear, which is not as familiar to engineers in this country as it should be, are put forward, particularly as regards the Moscicki condenser, which was specially developed and is largely in use abroad for this kind of work. It is pointed out particularly that this form of protector can be connected direct to the line without an air-gap or series resistance, and that there is no dielectric spark lag. Again, it is the only arrester discriminating adequately between the low frequency of the line and the high frequency of the surge, and it does not permit live current to flow during the time that it is discharging the surge, beyond the small charging current of low power factor which flows continually. The condenser is the only surge protective device which modifies

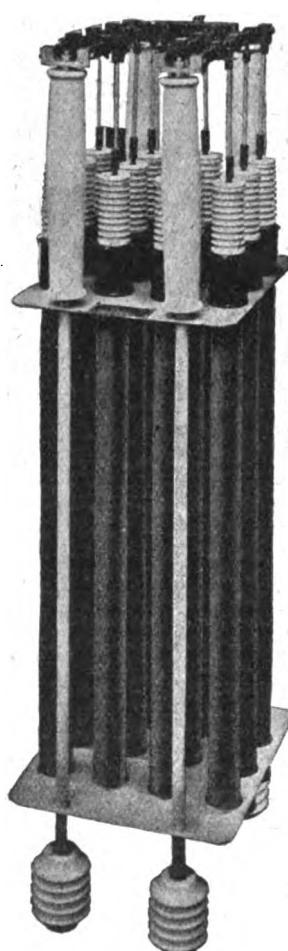

FIG. 1.—MOSCICKI CONDENSER.

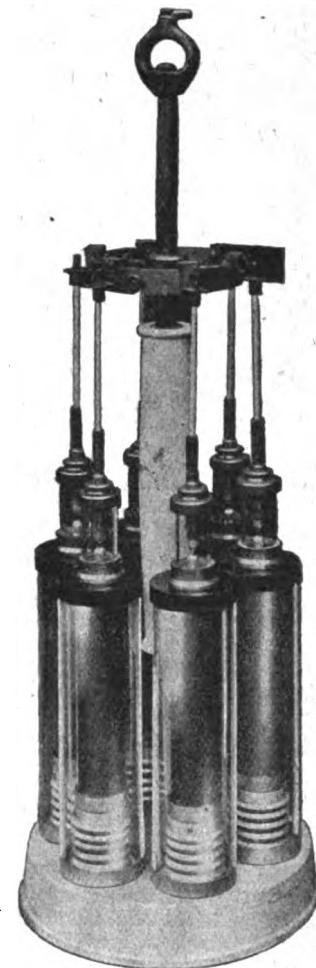

FIG. 2.—GILES VALVE.

the wave-form of steep-fronted waves, and when properly arranged is capable of effecting a reduction in the surge pressure of a 100,000 cycle per second surge to 0.067 of its value and a 1,000,000 cycle per second surge to 0.007 of its value. It will be remembered that the Moscicki condenser consists of a glass tube composed of a special glass mixture, the inner and outer surfaces being coated with chemically-deposited silver which is afterwards plated with copper. At the neck the tube thickens considerably in order to withstand the static stress which at this point is greater than at any other part of the surface. This construction enables the thickness of the dielectric to be reduced to a minimum, thereby giving a high capacity, whilst there is ample security against a perforation of the dielectric. The neck of the condenser is enclosed by a high-pressure china insulator, the space between the neck and insulator being filled with an insulating compound in such a way that the edge of the coating is completely buried in this mass, and no surface discharge can occur. Each condenser is mounted in an iron tube, the space between the condenser and tube being filled with a mixture of water and glycerine, so that any local

Because IT NOT ONLY SAVES 3/4 OF YOUR CURRENT BILL
BUT IS STRONGER, BRIGHTER, &
MORE DURABLE THAN ANY OTHER.

heating which might result in the perforation of the dielectric is rendered impossible. A view of a battery of small Moscicki condensers is shown in Fig. 1.

An appliance which meets the case where high pressures may be present without high frequency, such as where there is resonance with the fundamental or a low harmonic, is the Giles valve, which is in effect a multi-gap arrester with the individual gaps shunted by condensers. The way this apparatus is arranged is shown in Fig. 2. Summing up the comparison of the different methods of protection, it is pointed out that no single device, be it a condenser, aluminium arrester, multi-gap arrester, Giles valve, or any other, will of itself completely protect a system. One device will protect against high voltage, another will protect against high frequency, but no single one will protect against all. The condenser is the only one which protects against excess pressures of high frequency, and against steep wave front, and with it must be installed a complementary device to protect against surges of low frequency but high voltage. The Giles valve is the best for this purpose, and the combination of Giles valve and Moscicki condenser affords a thorough protection of the system.

The Bulletin further deals with protection against static charges by small inductance coils between line and earth and by the water-jet method, and the protection of continuous-current circuits by a special form of electrolytic condenser composed of two sets of aluminium plates wound together spirally round a vertical axis.

The circumstances in which protective gear is particularly necessary are discussed, and the conclusion is arrived at that, apart from the dissipation of surges of external origin, protective apparatus is essential at those two points where systems of different surge impedance, in which surges may reasonably be expected to originate, are connected together. Typical examples are the junction of long underground and overhead mains, a cable entering or leaving a sub-station or power house, a connection from a long overhead line to a large motor, and so forth. The exact nature of the protective scheme will depend upon the circumstances. Sometimes condenser protective gear will suffice, sometimes Giles valves will afford the necessary protection, while frequently the two will be combined.

GLASSHOUSE POT-MAKING AT EDISWAN WORKS

THE photographs reproduced in Figs. 1 and 2 will help to make clear a very interesting industry, which is little known to electrical trades, but is carried on by the Edison & Swan United Electric Light Co., Ltd., at their Ponders End Works. This industry is "glasshouse pot-making," the pots being used in the manufacture of glass for the bulbs and tubes of Royal "Ediswan" lamps. Our illustrations show the interior of a room specially built for the making

FIG. 1.—WORKING CLAY FOR GLASSHOUSE POT-MAKING.

of glasshouse pots. This room, when filled, holds 120 glasshouse pots of a size suitable for the furnaces at the company's works.

The clay of which these pots are made comes from the Stourbridge district, and is the finest mixture which can be procured for this class of work; it is delivered to the works in bags in a dry state, when it is taken in hand by skilled workers, who add the requisite amount of water, after which the clay is allowed to stand by for a time, when it is again taken in hand and tempered, being turned and trod by skilled men with their bare feet (see Fig. 1) until it is in a

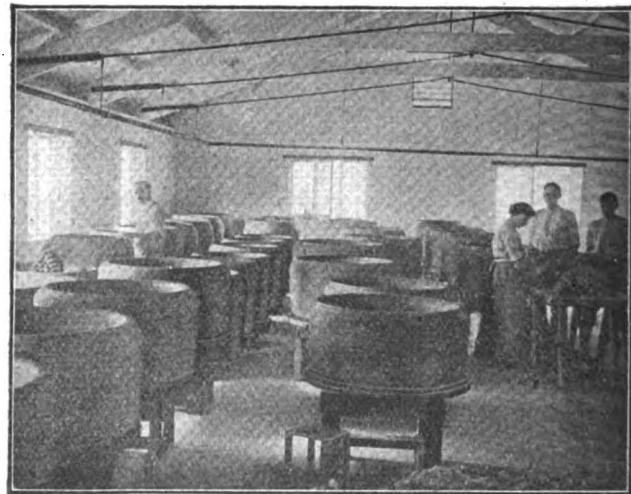

FIG. 2.—GLASSHOUSE POT-MAKING AT EDISWAN WORKS.

sufficiently plastic state for the pot-maker to start operations, various stages of which can be seen in Fig. 2. These pots require to be made at least 12 months before being used, the method adopted here being to dry them to a sufficient state of hardness to allow of their being moved to a room where more direct fire heat is allowed to play on them until they are sufficiently hard or dried to be transferred to the pot arch, when they require at least 14 days to burn sufficiently to temper them before being transferred to the furnace, when they are ready to be charged with the ingredients for the manufacture of the glass required for electrical work.

An illustration is also given in Fig. 3 of "Vitrite" lamp-

cap making at the Ediswan Works, which will help to show those who are unable to see for themselves that "Royal

"Edison" lamps are entirely manufactured at the Ponders End Works.

CORRESPONDENCE SHOP LIGHTING.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In December last (see ELECTRICAL ENGINEERING, Dec. 10th, p. 635) I sent a letter to your paper in regard to shop-window lighting in war-time, dealing with the amateurish attempts made by shopkeepers to conform to regulations. I drew attention to the much favoured method of wrapping tissue-paper around bare lamps, and pointed out that not only was this very ineffective, but was a distinct source of danger, as witnessed by the large amount of badly scorched tissue-paper seen. The note of warning which I struck in that letter was amply justified in the Press this week, where it was stated that the L.C.C. Fire Brigade was recently called to an outbreak of fire caused by crinkled paper round electric lamp bulbs in a shop-window. One is led to wonder how many small outbreaks, not necessitating the attendance of the Fire Brigade, have been caused by this highly dangerous practice. The system I mentioned in my December letter was the scientific lighting of shop-windows by means of concealed lighting units placed high in the window. This method ensures the effective lighting of the articles displayed with complete control to accord with the lighting restrictions of the police, and has the additional merit of being safe and free from danger of fire. A large number of shops have been lighted on this approved plan, and give absolute satisfaction to all concerned.

Yours very truly,

F. W. WILLCOX,

General Manager, Lamp and Wiring Supplies Department.
Mazda House, 77 Upper Thames Street, E.C.
July 24th, 1915.

"Manganesite."—As it has been stated in some quarters that "Manganesite," lately advertised in our pages, is a German manufacture, Messrs. John Hudson & Co.'s Successors (4 Victoria Warehouses, Mansell Street, London, E.) ask us to make it known that although, until the outbreak of the war, they sold goods made at their German works, since September they have sent out no "Manganesite" except that made at their works in London. The firm has decided to abandon the German works for good, and they assure us that there are no aliens—naturalised or otherwise—connected in any way with this business. During the last twelve months large quantities of manganesite have been supplied to the Admiralty, War Office, and other Government Departments.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

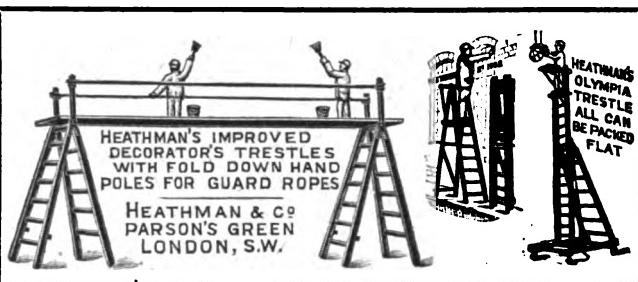

Bury.—Extensions at an estimated cost of £7,500 are to be carried out at the electricity works.

Coventry.—Subject to satisfactory assurances from the Minister of Munitions, the Electricity Committee recommends an expenditure of £91,417 upon new plant to deal with factories working on Government orders. The Council desires to be safeguarded against loss on capital account in the event of a cessation of the additional demand for power.

Earby.—Dynamo, battery, wiring, &c., at Sewage Disposal Works. Engineer and Surveyor, Council Offices. August 16th.

London: *Battersea-Fulham-Hammersmith.*—In connection with the scheme for linking up the Battersea, Fulham, and Hammersmith undertakings, the Battersea and Fulham Borough Councils have applied for sanction to the borrowing of £5,814 and £8,376 respectively as their shares of the cost. The Treasury has intimated to the London County Council that there is no objection to the loan in the case of the Battersea undertaking on the understanding that the expenditure is urgently necessary for the effective maintenance of existing supplies. The Finance Committee of the L.C.C. is advised that the only work which complies with the Treasury requirement is that relating to the linking up of the generating stations of the Battersea and Fulham Councils. It is proposed, therefore, to limit the loans for the present to the cost of this work, which is calculated at £2,618 in the case of both Battersea and Fulham; the cost of the main, with an additional £1,850 in the case of Fulham for a transformer.

Poplar.—The Finance Committee of the L.C.C. recommends sanction to a loan of £10,188 for new machinery. The Borough Council states that the proposals put forward are the minimum necessary to meet next winter's demands augmented by war requirements, and the L.C.C. Finance Committee states that there is good evidence in support of the application. The Treasury state that although they will not raise any objection to the borrowing on condition that expenditure under the sanction is limited during the war to purposes for the furtherance of the war, and the amounts authorised to be borrowed must be provided out of funds

under the control of the Borough Council without resort to other sources for the next eighteen months.

St. Pancras.—The long discussion between the Borough Council and the L.C.C. as to accelerating the repayment of certain outstanding debts on the electricity undertaking has been brought to a head by a resolution of the L.C.C. Finance Committee agreeing to a loan of £15,000 for a new turbo-generator, with the reservation that the order for the loan will not be issued until the Borough Council has agreed to repay, within a reduced period equivalent to one-half the periods now unexpired but not exceeding fifteen years, the debt now outstanding on the plant and machinery, for which a term of forty-two years has been granted, and which will, by the introduction of the new machinery, in the opinion of the Council, fall within the category of stand-by or reserve plant.

Woolwich.—The Finance Committee of the L.C.C. recommends sanction to loans of £1,117 for mains and £1,055 for house wiring. The whole of this expenditure is necessary for dealing with a supply of electricity to 220 houses forming part of a housing scheme which H.M. Commissioners of Works are carrying out at Eltham for workmen engaged in manufacturing war materials.—Sanction is also recommended to a loan of £4,700 for linking up the Borough Council's electricity undertaking with that of the South Metropolitan Electric Light & Power Co. The Director-General of Munitions has intimated that it is very desirable in the public interest that arrangements should be made at once for the two undertakings to be linked up. The scheme involves a 10,000-volt main and two 750-k.v.a. transformers and switch-gear.

L.C.C.—An expenditure of £11,800 is authorised for switch-gear in connection with a reserve supply of electrical energy for tramway purposes from outside sources.

Mexborough.—Application is to be made for a loan of £4,000 for new plant.

Rochdale.—A twelve months' supply of paper-insulated cable. Borough Electrical Engineer. August 4th.

Stoke-on-Trent.—An expenditure of £1,085 is contemplated upon a new sub-station.

Walsall.—Sanction has been received to the following loans:—Cables, £10,000; transformers, £5,500; switchgear, £3,444.

York.—The L.G.B. has approved of the following loans:—Mains, £7,047; rotary converters, £4,491; static transformers, £830; and services, £1,626. Some portion of the above has already been incurred, and the Board has warned the Corporation against incurring expenditure in future in anticipation of sanction.

Miscellaneous

South Africa.—The Johannesburg Corporation requires 8,600 drawn-wire spiral filament traction lamps; also spare parts for tramears. Tenders to the Town Clerk by August 25th. Copies of specification may be consulted at the Commercial Intelligence Branch of the Board of Trade, and it will be noted that the date for receipt of tenders is useful only to those firms who can instruct agents by cable.

APPOINTMENTS AND PERSONAL NOTES

Early last year an arrangement was entered into by the L.C.C. Tramways Department with Messrs. Kennedy & Donkin providing for Sir Alexander Kennedy to advise and report upon the extension of the Greenwich power-house, the retaining fee being £500 per annum, with a commission ranging from 3 to 5 per cent. on new constructive work. It is now proposed to continue this agreement as a yearly one with the same retaining fee and a commission of 5 per cent. on new constructive work up to £50,000 a year, and 4 per cent. on work exceeding that amount. In the case of new constructive work connected with the second stage of the extension at Greenwich, which is being carried out sub-

stantially to specifications prepared by the Chief Officer of Tramways, the commission is to be 3 per cent.

Mr. E. G. Okell. Borough Electrical Engineer to the old Plymouth Corporation, has been appointed to take charge also of the Devonport undertaking upon the resignation of Mr. J. W. Spark, on appointment as Borough Electrical Engineer at West Hartlepool. Mr. Okell's salary in future will be £600, rising to £650, per annum. Devonport was last year amalgamated with Plymouth.

Mr. R. M. Jockel. charge engineer in the York Electricity Department, has been appointed engineer at the Northern Counties Co.'s Malton power-house. Mr. Edwards, junior charge engineer, succeeds Mr. Jockel.

A shift engineer is required in the Stockton-on-Tees Electricity Department. (See an advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £88 to £89 (last week, £90 to £91).

Holidays.—The "Z" Electric Lamp Manufacturing Co., Ltd., will close their factory from August 2nd to 7th inclusive.

LOCAL NOTES

Birmingham: Treasury Restrictions on Loans.—Having considered the Treasury restrictions upon municipal loans, the Electricity Committee have informed the Town Clerk that sums amounting to £253,414 will be required to be borrowed during the current year in respect of the new power station. This large expenditure, it is pointed out, is absolutely necessary in consequence of the large demands chiefly from manufacturers of war materials.

Brighton: Electricity Deficit.—There was a deficit of £1,354 on the electricity undertaking last year. The total revenue was £4,224 less than in the previous year, but the working expenses, exclusive of capital charges, remain approximately the same. Coal has cost an average of 2s. 3½d. per ton more than in the previous twelve months, but owing to the more economical operation of the plant the weight of coal per unit sold has been still further reduced, being now 3·97 lb. as against 4·06 lb. in the previous year, and 4·18 lb. in the year before that. The total extra cost of coal was £2,966.

Bristol: Satisfactory Electricity Accounts.—There was a net profit of £6,374 upon the working of the electricity undertaking last year, after allowing for an expenditure of £3,524 upon works of a capital nature. The increase of 502 in the number of consumers is the largest in any year except 1913 1914, when the number was 541. The power connections now represent 19,542 h.p., and applications are in hand for some thousands of additional h.p. The revenue per unit sold has fallen to just under 1½d., whilst the generating costs have fallen to 0·668d., a record for the undertaking, and five per cent. below last year's figure.

Edinburgh: Estimates for 1916.—The estimated capital expenditure on the electrical undertaking for the current year is £37,000, which includes £23,000 for the new power station at Portobello. The charge for current for lighting purposes has been increased to 2½d. per unit, and on this basis a balance of £540 is estimated for the year.

Fleetwood: "Municipal Wiring."—Considerable discontent has been shown by the electrical contractors in Fleetwood because the employees of the Electricity Department have hitherto been allowed to carry out private installation work in their spare time. This is regarded as unfair competition. Moreover, the Council itself is not in a position to carry out wiring work. The Council has decided, however, not to take any action in the matter at present.

Warrington: Tariff Increases.—A 10 per cent. increase is to be made from August 1st on charges for electricity for lighting and tramways, and 15 per cent. increase for heating and power, except where the price is regulated by a stipulation as to the varying cost of coal.

SUMMARY

WE deal with the coal supply outlook in a special article (p. 328).

TWO further electric miners' lamps have been approved by the Home Office, making a total of 17 for general use and nine for special purposes (p. 328).

SEVERAL patents relating to electrical working in mines and to electrometallurgy have been published during the past month. The subjects include electric signalling gear, switchgear, safety lamps, and electric furnaces (p. 329).

A SYSTEM of shot firing controlled from the surface in use in an American mine is described (p. 329).

THE connections of star-delta starters for induction motors are discussed in our Questions and Answers columns (p. 330).

PARTICULARS are given under Electric Traction Notes of some new American electric locomotives (p. 331).

AMONG the subjects of specifications published by the Patent Office last Thursday are electrolytic meters, wireless telegraphy, metal filament lamps, and telegraph relays. A patent for a method of ventilating accumulators in submarines expires this week after a full life of 14 years (p. 332).

AN interesting lecture on field telephones was given last week before the Royal Society of Arts. Flag signalling has practically gone out of use at the front, the telephone taking its place. The bell call has been abandoned in favour of the buzzer, as with the latter Morse signalling can be carried on where, owing to the

noise, speech might be impossible. Methods of multiple lines for maintaining continuous communication were described, and a scheme for training telephonists was suggested (p. 333).

A LOAN of £7,500 is to be applied for by the Bury Corporation; an extension scheme is to be carried out at Erith, and a converter is required at Manchester (p. 333).

THERE was a deficit on the Glasgow electricity undertaking last year. Southampton has abandoned its "Point Five" tariff. Proposals are made for investigations into the working of the Manchester and Bristol electricity undertakings, but neither need be taken too seriously. A West Ham electrical employee has been awarded £350 compensation in respect of an electric shock (p. 334).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING AUGUST 7TH, 1915.
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday, Wednesday, and Friday:—Drills 6.30 and 7.30.

(There will be no drill on Monday, August 14th.)

Applications for Enrolment:—All applications for enrolment should be sent to the Commandant, Marconi House, Strand, from whom all particulars can be obtained.

E. G. FLEMING.

(Company Commander and Acting Adjutant.)

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE prospectus of the University Courses in Electrical Engineering and other subjects for the forthcoming session at the Manchester Municipal School of Technology has been issued, which contains full summaries of the hours per week that are devoted to the different subjects, general details of the organisation and work of the College, and an account of the equipment of the laboratories. The principal of the school, which works in connection with the University of Manchester, is Mr. J. C. Maxwell Garnett, and the Electrical Engineering Department is under Prof. Miles Walker, assisted by the following lecturers and demonstrators: Mr. J. Lustgarten, Mr. A. E. Moore, Mr. J. Hollingsworth, Mr. F. Shaw, and Mr. B. Hoyle.

A special course of instruction in electrical measurement and practical electricity, under Prof. E. Taylor Jones and Mr. W. E. Williams, will be commenced next term at the University College of North Wales, Bangor. Full particulars can be obtained from Mr. J. E. Lloyd, Secretary and Registrar.

Obituary: Killed in Action.—News has been received that Major Gardiner (R.E.), who was reported missing in December, was killed in action at Givenchy on December 20th. Major Gardiner was an associate member of the Institution of Electrical Engineers, and did much work in India. Some years ago he invented a system of cab signalling on railways.

ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

THE COAL SUPPLY OUTLOOK

TAKING all things into consideration it is not too much to say, as a result of the national conference between the mining industry and the Government in London on Thursday, that the prospects of increased supplies of coal are not promising. According to Sir John Simon, who presided over the conference—the object of which was to appeal to the owners and men to do everything possible by way of relaxation of rules and regulations, harder work, and so on, to increase the output—our coal supplies are short by some 3,000,000 tons per month, owing to the enlistment of 250,000 miners. The importance of this shortage to the electricity undertakings of the country, not to mention other large users, cannot be overstated, and the seriousness of the position is not lessened by the frame of mind of both owners and miners at the conference. Whilst the political speeches of the Home Secretary and the Minister of Munitions may appeal to the popular imagination, and the general proposition of the need of more coal in the national interest is accepted by owners and miners alike, the fact still remains that any extra efforts on the part of the coal mining industry are to be coincident with concessions of one sort or another by the Government. It is difficult to avoid the conclusion from the speeches that whilst the owners are doubtful of what the Government may do in the future, the miners distrust both owners and Government. The resolution which was passed to the effect that every effort should be made to secure the greatest possible output of coal during the period of the war binds neither side to anything specific, and, eliminating the political speeches, the whole tenor of the proceedings was that the owners and men must be allowed to confer and decide what steps, if any, could be taken and that anything so decided upon must be accepted as final. The hint was given by the men that any interference with the Eight Hours Act would be resented, whilst the owners urged that greater facilities for the export of coal should be given.

Other issues, however, are involved. The miners take up the position that an increased output per day per man is a physical impossibility, and add that even if in one or two isolated cases a miner may feel physically able to increase his output, there must be safeguards against the owners using the increase as a pretext for lowering the piece rate over the whole district. It is admitted, however, that extra output is possible in another direction. In Yorkshire, pits are said to be working two-and-a-half, three and four days per week whilst the men are willing to work six, but are prevented from doing so through lack of trucks. Therefore there is an indisposition for a general abandonment of the Saturday holiday without an assurance that trucks will be available to carry away the increased output. Again, the suggestions for lowering the age of boys to be employed and increasing the number of women employed at the surface are objected to, the latter by both the miners and owners.

The colliery proprietors claim the right to ask for a clear and well defined Governmental policy, which will dispel the misgivings in the minds of many as to what may be done in the future. The industry, it was said, wants to know that the Government is behind it, and when that was known every possible restriction

in regard to the output and distribution of coal would be withdrawn as far as possible.

So far as the Government is concerned, their position at the moment is that they undertake to make good immediately after the war any modifications that may be made of established rules and practices.

ELECTRIC SAFETY LAMPS FOR MINES

A HOME OFFICE Order, dated June 15th, approves the following electric miners' lamps.

The "Rutter" Miners' Electric Safety Lamp (made by the South Wales Electric Safety Lamp Co., 14 Birch Avenue, Treforest, Pontypridd). According to the official description this lamp, which is approved for general use, possesses the following essential features: A case of pressed steel. An electrical accumulator, the terminals of which are fitted with spiral springs carrying rubbing contacts. The construction of the accumulator is such that the release of gas generated by chemical action is allowed, but no liquid is permitted to escape whatever the position of the lamp. A cover of steel carrying a dome of stout glass protected by steel pillars, and kept in position by a disc of insulating material to which are fitted the bulb-holder and the electrical contacts. The cover forms a flame-tight connection with the case. The switching on and off of the light is effected by turning the cover round about a quarter-turn. A magnetic lock, mounted on the cover, so constructed that the locking bolt can only be withdrawn by a powerful electromagnet.

Among the conditions subject to which it is approved are the

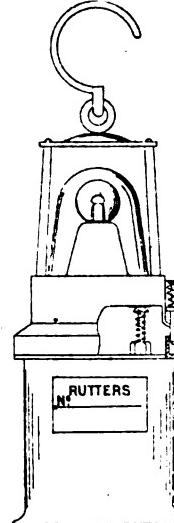

FIG. 1.—RUTTER LAMP.

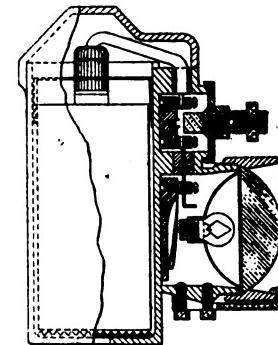

FIG. 2.—OLDHAM
EMERGENCY LAMP.

following:—That the total weight of the lamp is not more than 4½ lb. That the lamp shall be capable of maintaining a light of not less than 1 candle-power all round in a horizontal plane throughout a period of not less than 9 hours, and also of giving a light of not less than 1·5 candle-power over an arc of 45 degrees in a horizontal plane. An illustration of this lamp is given in Fig. 1.

The Oldham "Emergency" Electric Lamp, No. 2 Bull's-eye (made by Oldham & Son, Denton, Manchester). This lamp is a modification of the Oldham "Emergency" electric lamp (see ELECTRICAL ENGINEERING, April 3rd, 1913, p. 187), with the following variations:—The case may be of solid drawn steel or brass. The cover is screwed on and secured by either a lead plug or a magnetic lock. The lens ring is secured by a clip held in position by a screw over which a lead seal is placed. Electrical connection with the accumulator is by means of spring brass contacts with brass studs on an insulator of teak or other non-conducting material. Among the conditions subject to

which it is approved are the following :—That the total weight of the lamp is not more than 6½ lb. That the lamp shall be capable of maintaining a light of not less than 1·5 candle-power throughout a period of not less than 10 hours. That the lamp shall be used by officials only, or for work of rescue or exploration in the case of an accident or other emergency. An illustration of this lamp as originally approved is given in Fig. 2.

The complete list of approved electric safety lamps is given below :—

For general use.—Bristol, Type B.T. 4 V. (Bristol Electric Safety Lamp Works); B.A.C. (British Accumulator Co., Ltd.); "Ceag" ("Ceag" Miners' Supply Co., Ltd.); Turquand-Kingsway (General Electric Co., Ltd.); Gray-Sussmann, Nos. 3 and 4 (W. E. Gray); Manley and Sandy (M. & S.) (Manley & Sandy, Ltd.); Joel-Fors, Type 403 M. (John Mills & Sons); Oldham (Oldham & Son); Pearson (Pearson & Sons, Ltd.); Thomson-Rothwell (Rothwell & Co., The Thompson Co.); Rothwell, No. 3 (J. H. Rothwell & Co.); Rutter (South Wales Electric Safety Lamp Co.); Varta (Tudor Accumulator Co., Ltd.); Wolf, Alkaline, Wolf, Lead, and Wolf, No. 2 (Wolf Safety Lamp Co.); Worsnop (Worsnop & Co., Ltd.).

For use by officials or for special purposes only.—Bristol, Type B.R. 4 V. (Bristol Electric Safety Lamp Works); Float Patent (Float Electric Co., Ltd.); Joel-Fors Electric Inspection Lamp, Type 303 C, and Joel-Fors Electric Hand Lamp, Type 403 H (John Mills & Sons); Oldham "Emergency," Oldham "Emergency," Type No. 2 Bullseye, and "Oldham" Shaft and Roadway, Types "A" and "B" (Oldham & Son); Varta, Type 2 Et 4 (Tudor Accumulator Co., Ltd.); Wolf Rescue, No. 2 (Wolf Safety Lamp Co.).

ELECTRICAL MINING AND METALLURGICAL PATENTS OF JULY

Mining.

In Specification No. 23,348 of 1914, the Allgemeine Elektricitäts Gesellschaft describe a system of enclosed switchgear for mining and other purposes with all live parts immersed in oil or embedded in a cast mass of insulating material arranged so that the several sections can be isolated and removed with safety without interruption of the supply. The gear consists of separate box-like units, each containing a bus-bar section and an oil switch branched therefrom, the connection being made between the bus-bars of the several switch sections and the main cables by removable plug connections.

A system of electrical signalling in collieries is described by H. Green and W. de M. Landon in No. 20,342 of 1914, for enabling men in charge of wagons to signal one to another from any point when a wagon is being sent along the track. There is a single main line of low-voltage normally-closed circuit, and a number of local bell circuits are provided, equipped with suitable relays so that the bells ring when the main circuit is broken. The main circuit is provided at intervals with enclosed spring contacts so that the continuity can be temporarily broken by pulling on the wire itself, and in this way the desired signal can be given from any point.

In No. 18,870 of 1914, G. Pearson describes a simple form of combined battery contact and lamp-holder for electric miners' lamps.

In No. 1,433 of 1915, G. Saint describes a special form of mercury globule contact-maker for releasing and actuating mine winding signal indicators. This consists of a tilting or revolving tube, the bore of which is expanded at the ends and sealed to retain a globule of mercury, which on tilting or rotation of the tube travels from one end to the other, connecting during its passage two terminals in the constricted part of the tube, and thus momentarily completing the circuit when a certain speed is reached.

The Sterling Telephone and Electric Co. and F. G. Bell describe their system of electric signalling for mines in Nos. 13,062 and 18,661 of 1914. The first of this is concerned chiefly with the details of the form of signalling being used. In this key, the operating lever normally rests and returns under gravity to a position from which it is only brought to the operating position by movement substantially opposite in direction to the actual operating or contact-making movement. The second specification describes a simplified arrangement of connections using a smaller number of relays. Each lamp relay transfers the signal circuit to the succeeding relay, and interrupts the hold on contact of the preceding relay.

A simple magnetic lock for miners' electric safety lamps, which takes the form of a self-contained removable padlock, is described by J. Davis & Son, Ltd. (Derby), and W. H. Davis in Specification No. 21,040 of 1914.

Electro-metallurgical.

F. W. Highfield, in Specification No. 6,865 of 1914, describes a process for the reduction of zinc oxide, &c., which consists in feeding the oxide directly on to the glowing surface of a body of electrically-heated carbon maintained at a temperature of about 1,050° C. in an atmosphere of carbon monoxide, maintained as far as possible free from carbon dioxide by exclusion of the air from the heated carbon. The molten zinc produced percolates by gravity through the carbon bed, and is collected and passed into a cooling chamber containing a neutral or reducing atmosphere.

The same inventor in No. 68,607 of 1914 describes a process for recovery of metal from complex sulphide ores, consisting in roasting the charge of ore in a furnace, then forming a reducing atmosphere in the same furnace, and heating the charge by electrical means to obtain reduced metal and matte, separating and cupelling the metal so reduced in an electrically-heated cupelling hearth, and reducing the oxide resulting from the cupellation in a reducing furnace that is also electrically heated.

ELECTRICAL SHOT FIRING FROM THE SURFACE

A SYSTEM of electric shot-firing from the surface in use in a mine in Kansas is described in an article in the *American Colliery Engineer*, abstracted in the *Colliery Guardian*. The two main and one return leads down the mine are connected to a three-pole switch about 30 ft. from the pit bottom, and a 6-foot flexible gap switch is provided some 120 ft. further in the mine as protection against lightning and a safeguard against premature shot-firing. A copper earth-wire extending through the entire mine serves as a protection from accumulated static charges. From the gap switch wires are carried to the "spark boxes," each having its own earth switch. These boxes contain a solenoid and trigger arrangement, by which, when set, the first current impulse received is directed to the local firing circuit and all succeeding ones to the circuit of the next box, which in like manner uses the first impulse to fire its own shots, and hands on the remainder to the next. Thus all the groups of shots are fired in succession.

The shots are fired in the evening after all the men have been checked out of the mine. It is the duty of the shot-firer to fire the shots as well as to see that there are no men in the mine, and also that the wiring, spark boxes, and other apparatus are in good order. Before firing the shots he must go through the mine and connect the shot wires to the spark boxes, and at the same time throw out the earth switch beneath each box. He then comes to the shaft, owing in the 6-ft. flexible gap switch and the three-pole switch, and comes to the surface, where he starts the dynamo, tests the circuit, and fires the shots. The shots are tested by passing a current from a single dry cell through the circuit supplied by each spark box, before the shots supplied by that box are fired. The shots are fired alternately on the east and west sides of the mine. After completing the firing, the shot-firer goes immediately into the mine, opening the three-pole switch and the 6-ft. flexible gap switch, and then he goes to each spark box, and disconnects the firing wires and closes in the earth wire switch. Current of 20 to 30 amperes at 175 volts is used. It is probable that not more than 50 to 75 volts is necessary to produce sufficient pressure to overcome the resistance of the firing circuit; 0·4 ampere is sufficient to explode a fuse; while 0·9 ampere is sufficient to work a box.

Diesel Engines.—At a recent meeting of the Diesel Engine Users' Association the question of a suitable allowance for depreciation of Diesel engine plant in connection with income tax assessment was further considered, and after some discussion the following resolution was unanimously passed :—"That in the opinion of this Association the present allowance made for depreciation by wear and tear on Diesel engine plant by the Inland Revenue Authorities is inadequate, and that an allowance at the rate of at least 15 per cent. per annum should be claimed." This meeting was held at Kingston, where the members enjoyed the hospitality of the Mayor and Mayoress, and had the opportunity of meeting members of the Electric Lighting Committee of Kingston-upon-Thames. A visit was afterwards paid to the electricity works, where the Diesel engines were seen at work. The plant consists of two engines of 400 and 500 b.h.p. respectively, the smaller engine being of the four-cycle horizontal type (four cylinders), and the larger of the two-cycle horizontal type (two cylinders). The next meeting will be held in October. Information and particulars concerning the Association can be obtained from the acting hon. secretary, Mr. Percy Still, 19 Cadogan Gardens, London, S.W.

**QUESTIONS AND ANSWERS
BY PRACTICAL MEN**

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,454.

Two 95-kw. auto-converter are being driven from a 500-volt system, and are supplying current at 300 volts to a motor load. When the machines are paralleled an equalising switch is closed. Until recently, the machines when started up built up to a pressure of 330 volts each and no trouble was experienced in paralleling them; but recently for some unknown reason one machine builds up to 350 volts. The result of this is, the equalising switch is burnt out after the machines have been operated a few times. What is the cause of this rise in pressure on one machine, and what is the best way to locate the fault and remedy it?—"ESTIMATOR."

(Replies must be received not later than first post, Thursday, August 12th.)

ANSWERS TO No. 1,452.

Below are two diagrams of a three-phase star delta starting-switch showing contacts made when in the starting and running positions. Please show connections to motor terminals and mains. In Fig. 2 numbers 1 and 4 terminals are the ends of

Fig.1.

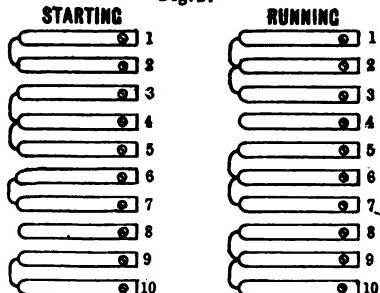

Fig.3.

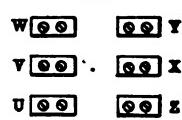

Fig.2.

one circuit as tested by a lamp, also numbers 2 and 5, 3 and 6, two other circuits. The terminals of another motor are lettered as in sketch 3. As received from the makers, the terminals marked X Y Z are short-circuited. Could this motor be coupled to a star delta starting-switch? Why is the lettering of the two top terminals on the right reversed? W and Y are not the

ends of one circuit, as there are 13 megohms between them. Give a diagram showing the connection of the terminals to motor windings.

The first award (10s.) is given to "Y. Z." for the following reply:

The function of a star delta switch, when used in conjunction with a squirrel-cage motor, is to reduce the starting current by reducing the volts per phase at starting. This is done by coupling up the three phases in star at starting, which makes the volts per phase only 57.7 per cent. of the full line volts. After the motor is going the connections are changed so that the three phases are coupled in delta, having therefore the full voltage on them. It is clear that the motor must in this case be designed to work with its phases coupled in delta. Figs. 4 and 5 show the diagram of what happens. M_1 , M_2 , M_3 are the three mains, 1-4, 2-5, 3-6 are the three phases, the numbers corresponding to the terminals between which the question states they are connected. The change from star to delta is made by breaking the star point, and connecting 4 to M_1 , 5 to M_2 , 6 to M_3 . This is accomplished by arranging the connections as shown in Fig. 6, where the numbers of the contacts themselves, shown in the question as 1 to 10, are omitted for clearness, while M_1 , M_2 , M_3 indicate the mains, and T_1 to T_6 show the terminals, numbered as in the question, and connected to the phases as described. The starting and running connections are combined in one diagram, and it will be seen that everything required is accomplished. The two contact bars numbered 4 and 8 in the question, which are shown unconnected to other bars respectively in the two diagrams of the question, are to

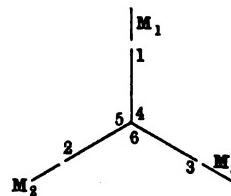

Fig. 4.

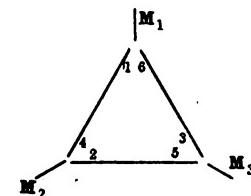

Fig. 5.

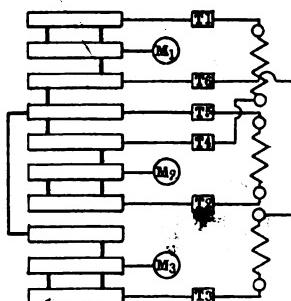

Fig. 6.

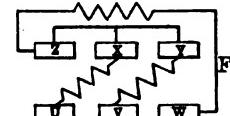

Fig. 7.

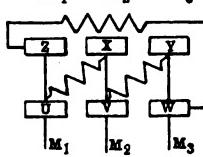

Fig. 8.

be connected together as shown, and are therefore both coupled to T_5 . This answers the first part of the question, as it shows the complete connections of the switch to the motor terminals and mains.

In regard to the second motor, inquired about in the second part of the question, the arrangement of the terminals there indicated is merely a matter of convenience. If U , V , W are the three ends of three phases, the other ends of the same phases, in the corresponding order, are X , Y , Z , i.e., the phases are between UX , XY , YZ respectively, as shown in Figs. 7 and 8. Instead of going straight across between terminals, the phases are coupled zig-zag as indicated, in order that all motors, whether star or delta connected, may have their external mains and phases connected to the terminals in exactly the same manner, and may have the ends of the phases interconnected for coupling to the mains in a much simpler and neater manner than if the terminal arrangement were anything else. For star connection it would evidently, from Fig. 7, be all right to have X opposite U , and so on, as all that is required is to couple together X , Y , Z . But in delta connection, ends of different phases have to be connected, and the arrangement chosen, as shown in Fig. 6, makes it possible to do this very neatly by joining UZ , VX , WY , which are respectively opposite to each other. In this case, if the ends of phases were opposite, the external connections between terminals would have to be zig-zagged and crossed, which would be much less convenient. Thus there is a definite reason, that of simplicity and neatness, for displacing the terminals each one place along on one side (which is a more correct way of putting it than to say that the lettering is reversed, though this also is incidentally a fact).

The motor referred to is evidently connected, as in Fig. 7, with XYZ connected together. It is therefore a star-connected

motor, and Fig. 7 is the diagram of connections between terminals and windings asked for. This motor would not be correctly used if coupled up to a star delta starter. For, as has already been made clear, the running condition of a motor so used is that the phases work delta connected. But this motor is meant to work star connected, and if put on the mains delta connected would have full volts on each phase. This is 1.73 times too many volts per phase obviously, and the motor would be entirely upset in all its constants. It must therefore be started by using an auto-transformer. It is assumed, of course, to be squirrel-cage.

The second award (5s.) is made to "J. E. R. R." who writes as follows:—

The diagrams show the several connections desired. Figures 9 and 10 show the connections of the start delta starting switch for star and delta positions. The small diagrams underneath show how the switch connects the phase ends. The arrows show the direction of the currents at one particular instant. It will be seen that at the same instant the directions are the same for star or delta positions, which ensures the direction of the field to be the same. This is an important point in coupling up any star delta starting switch, as if a phase be crossed the direction may be different in delta from that in star, with the result that serious damage may be caused in the motor when switching over. It will be seen that in addition to the line and motor connections an additional permanent connection is required between contacts 4 and 8 on the switch.

Figures 11 and 12 show the probable coupling of the phase ends of the motor in Figure 11 of the question, as it is usual

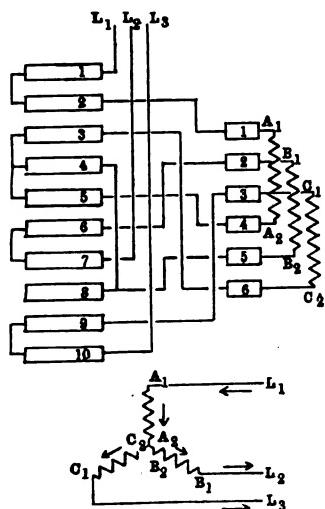

Fig. 9.

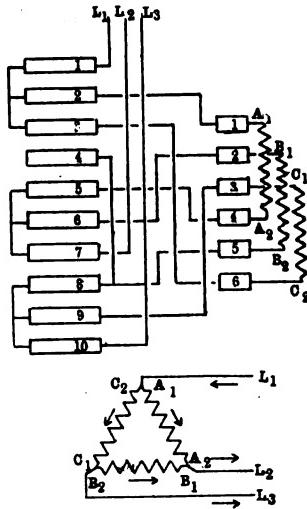

Fig. 10.

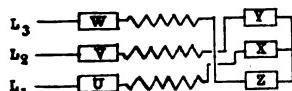

Fig. 11.

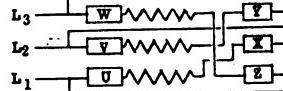

Fig. 12.

to letter the phase ends in alphabetical order respectively. The lettering of terminals X and Y are reversed, so as to indicate the right phase ends. The order of bringing out the phase ends may have been changed for one or two reasons. It may be more convenient, or mean less cable inside the motor, but the most probable reason is that it makes a very simple connection whether motor is coupled star or delta. It will be seen that to couple the phases up star it is only necessary to couple the terminals on one side together, whilst for delta it is only necessary to put connectors across, coupling the terminals in pairs. The figures show how such a motor could be coupled up star or delta. It could be coupled up to any star delta starting switch, using U V W as phase ends, with X Y Z as the other ends respectively. It could be controlled with the starting switch in Figures 9 and 10 if the phase ends U V W are connected to terminals 2, 6, and 9 and phase ends X Y Z to terminals 5, 8, and 3 respectively, and of course the permanent connection made between terminals 4 and 8, the line terminals being the same.

It should be borne in mind that as the makers delivered the motor coupled star it may be designed to run on its normal voltage star connected. If so, running it delta connected on full voltage would be equivalent to 73 per cent. increased voltage across each phase winding, which would probably burn the motor out on load. If it is in doubt as to what the normal running connection should be, then a test should be taken by running the motor light, star connected. If when so connected the light load current is about 30 per cent. of the normal full load current, then it can be assumed that its normal connection is star; but if the light load current is about 10 per cent. of the full load current, then the normal connection is delta.

CORRESPONDENCE

QUESTION 1,551. PLATING DYNAMOS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—There is a much better practical solution to the problem of multiple-voltage dynamos for plating than either of those given by your prize-winners in the current issue of ELECTRICAL ENGINEERING. It should be said, in justice to them, that the potential requirements of plating are a number of definite voltages, corresponding to the metals to be deposited, and not that of regulation between certain limits, as propounded by the question.

The practical solution referred to was given by Mr. W. B. Sayers a good many years ago, when he designed and patented the device of forming several non-sparking brush positions by slotting the pole pieces at appropriate places, so that brushes carried at the corresponding commutator radii give different calculated voltages in reference to brushes carried at the normal commutating diameter. A good many of these machines were made by Messrs. Chamberlain & Hookham and sold in the Birmingham district. They could be used for two or three baths, say nickel and silver, or copper silver and gold, simultaneously—which your prize-winners' plans could not—and were very successful. I cannot say whether such machines are still on the market. The device has other applications, e.g., a third brush may be used to give an exciting voltage, where a shunt-wound machine is required of such size and voltage that the shunt-winding would be of inconveniently fine wire if calculated for the main voltage. This arrangement is particularly suitable for small motor-generator sets off 440 volt or traction supplies, and is quite successful in practice.

Streatham, S.W.
July 30th, 1915.

I am, Yours, &c.,
HENRY M. SAYERS.

ELECTRIC TRACTION NOTES

The following dividends have been announced by the group of railways in London affiliated to the Underground Electric Railways Co. of London, Ltd.:—London Electric Railway, full dividend on the 4 per cent. preference stock and 1 per cent. on the ordinary; Metropolitan District Railway, full dividend on the 4 per cent. guaranteed stock, 4½ per cent. on the first preference stock, and 3 per cent. on the second preference stock; Central London Railway, 8 per cent. on the undivided ordinary stock and 4 per cent. on the preferred ordinary stock; City & South London Railway, 5 per cent. on the 1891, 1896, 1901, and 1903 preference stocks.

The *Electrical World* (New York) has collected a number of statistics regarding the cost of running of electric commercial vehicles in actual regular service. The average figures of the total cost of running per vehicle per day, including interest, depreciation, &c., work out as follows:—700 lb. load, \$5.68; 1,000 lb. load, \$6.84; 2,000 lb. load, \$7.56; 4,000 lb. load, \$8.92; 7,000 lb. load, \$10.88; 10,000 lb. load, \$11.74. The average daily mileage of these vehicles is not given.

Some particulars of the new electric locomotives which are being made by the American General Electric Co. for the Chicago, Milwaukee, and St. Paul Railway are given in the *General Electric Review*. These are of the 4-16-4 articulated type with four trucks and two bodies, and are equipped with eight 375 h.p. (continuous rating) wound for 1,500 volts D.C. and connected two in series on the 3,000 volt line. The total weight is 520,000 lbs., of which 400,000 lbs. is on the drivers. The passenger and freight locomotive will be similar except for their gear ratio. The passenger locomotive will haul a 300 ton train at 60 m.p.h. on the level and haul a 600 ton train up 20 miles at 2 per cent. up-grade, and the freight locomotive will deal with trains up to 2,500 tons, and will exert a tractive effort to 85,000 lbs. at 15-25 m.p.h. Each motor drives through a twin gear connected to the axle through springs. Regenerative braking is provided for, and a new form of pematograph collector with a double bow contact. Each half of the complete locomotive can be used separately if desired.

The Wolverhampton Corporation Tramways last year contributed to the relief of rates £3,744, equal to a 2½d. rate. The reserve and renewals fund now stands at £53,987, which is the maximum allowed, being one-fifth of the capital expenditure.

Manufacture of War Material in American Electrical Works.

The *Elektrotechnische Zeitschrift* of July 22nd contains a bitter attack on the American General Electric and Westinghouse Co.'s, who are, it is stated, manufacturing war material on a large scale for the Allies.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 29th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

26,899/13. **Electrolytic Meters.** H. S. HATFIELD and CHAMBERLAIN & HOOKHAM, LTD. The use of rhodium metal or alloys for the electrodes of electrolytic meters to obtain more accurate proportionality between the gas given off and the current than with platinum.

2,214/14. **Wireless Telegraphy.** R. GOLDSCHMIDT. A multiple spark gap for wireless telegraphy, comprising a taper plug carrying electrodes, a socket carrying an equal number of electrodes on its inner surface, and having the same taper as the plug, the two sets of electrodes being arranged in staggered order, so that each plug electrode is partly overlapped by two on the socket and vice versa. (Three figures.)

9,110/14. **Incandescent Lamps.** C. GLADITZ. Metal filament lamps in which the filament is wound on and supported by a structure composed of beads of silica strung on a wire of tungsten or other refractory material. (Four figures.)

16,471/14. **Telegraph Relays.** EASTERN TELEGRAPH Co. and J. B. DAVIES. Cable relays, including a suspended or pivoted contact arm carrying a very fine wire adapted to make and break contact with a liquid electrolyte, so that the moment of the capillary pull of the liquid upon the conductor is so reduced as to be negligible compared with the moment of the force due to the received signal. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: WATERS and CALLENDER'S CABLE & CONSTRUCTION Co. [Cable joints, &c.] 13,933/14.

DYNAMOS, MOTORS AND TRANSFORMERS: SIEMENS-SCHUCKERTWERKE GES. [Braking single-phase motors] 299/14; PARSONS [Cooling generators] 16,986/14; ECKMANN [Winding motors] 17,037/14; JUHLIN [Ventilation of dynamos] 18,281/14.

Electrometallurgy and Electrochemistry: MARKS (*Siemens & Halske A.G.*) [Lead anode] 284/14; F. KRUPP A.G. [Electrode furnaces] 742/14; PLANCQ [Electrolytic apparatus] 21,727/14.

Ignition: TISMER [Sparkling plugs] 9,444/14; WILSON [Ignition and lighting generators] 16,737/14.

Incandescent Lamps: LUDECKE and BRIMSDOWN LAMP WORKS, LTD. [Filament supports] 27,157/13; B.T.-H. Co. (A.E.G.) [Sealing in] 1,056/14.

Instruments and Meters: SCHOELLER & Co. [Combined ammeter and voltmeter] 27,473/13; B.T.-H. Co. (G.E. Co., U.S.A.) [Meters] 16,869/14.

Switchgear, Fuses, and Fittings: CACHA [Locking lamp-holder] 900/14; DIRKS [Lift switches] 9,289/14; WEST [Controllers] 14,294/14; SMITH and LOACH [Lamp-holders] 16,149/14.

Telephony and Telegraphy: BARON (*Aldendorf*) [Telephone switching systems] 27,515, 28,291, & 28,833/13; ALDENDORF [Telephone switching systems] 28,362 & 28,502/13; VON ARCO and MEISSNER [Wireless transmission] 29,946/13; BARON (*Heimann*) [Automatic telephones] 450/14; SIEMENS & HALSKE A.G. [Automatic telephones] 459/14; RELAY AUTOMATIC TELEPHONE CO., BRYANT and WARD [Automatic telephones] 16,411/14; HEYLAND [High-frequency generator] 17,331/14; CONNER and ROBINSON [Telephone systems] 17,446/14; SIEMENS BROS. & Co. (*Siemens & Halske A.G.*) [Automatic telephones] 21,793/14.

TRACTION: VON KANDO [Electric vehicles] 963/14; JOHNSTON and GREEN [Trolley heads] 3,318/14.

Miscellaneous: KRAUSE [Separating dust from gases] 27,059/13 and 27,060/13; MOORE LICHT A.G. [Vacuum light apparatus] 27,426/13; ROMANES [Contact cramps] 27,590/13; CONWAY [Insulating gloves] 16,111/14; BANNEVER [Alarms] 16,597/14; BENDIXEN [Fire alarms] 17,611/14; GRINSTED [Production of intermittent currents] 1,007/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

IGNITION: DAIMLER MOTOREN GES. [Sparkling plugs] 9,783/15.
TELEGRAPHY: SRNKA [Telegraph systems] 10,228/15.

Amendments

29,712/13. **Wireless Telegraphy and Telephony.** R. C. GALLETTI and GALLETTI'S WIRELESS TELEGRAPH CO. A request for correction of clerical errors in this specification has been made. The system of transmission described depends for its control on the variation of a resistance in a shunt circuit in parallel with a part of a series multigap discharger.

4,082/13. **Electrolysis.** C. WHITE. Slight alterations have been allowed in the wording of this specification, which describes an electrolytic process for the preparation of oxides, hydrates, and other components of metals.

Opposition to Grant of Patents

4,655/14. **Motor Car Lamps.** A. CHRISTMAS. A grant has been allowed in this application in spite of opposition. The specification describes a system in which the lamps are fed from an ignition magneto through inductances contained in the lanterns.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:-

15,819/01. **Battery Ventilation in Submarines.** R. McA. LLOYD. A method of providing egress for gases evolved on charging of accumulators in submarines, etc., by a pipe connected to the closed battery box with a valve for shutting off when required and means for providing suction in the pipe to sweep out the gases by drawing air into the battery box by a non-return valve and not through the pipe.

16,062 and 16,063/01. **Magneto Ignition.** F. R. SIMS and R. BOSCH. Constructive details of an improved form of sparking plug for low tension break-spark magneto ignition.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS, AND TRANSFORMERS: ELEKTRICITÄTS A.G. vorm. W. LAKMEYER & Co. [Dynamo regulation and motor control] 5,977/05, and [Train-lighting dynamos] 8,526/06; C. J. SPENSER and J. W. DAWSON [Variable gauge tramcar trucks] 8,959/06; SIEMENS BROS. DYN. WKS. and KIEFFER [Communicators] 8,133/08.

Electrochemistry and Electrometallurgy: G. W. J. ALLEN [Electrolytic water preparation] 9,002/06.

IGNITION: H. W. HELLMANN [Magneto ignition] 8,858/02.

INCANDESCENT LAMPS: A. G. BLOXAM [Metal filaments] 9,020/06; B.T.-H. Co. (G.E. Co., U.S.A.) [Attachment of filaments to leading-in wires] 8,641/07.

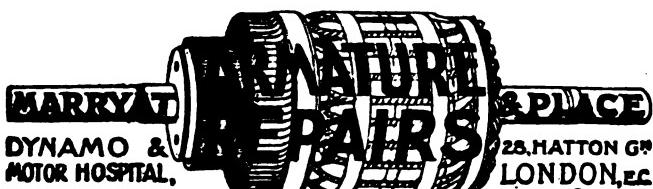

TRACTION: B.T.-H. Co. (J. B. LINN) [Multiple unit control] 8,557/02; F. H. HIGLEY [Railway signalling] 8,421/04.

Engineering Institutions Volunteer Training Corps.—A card is being issued calling attention to the objects of the Corps, which it is hoped that employers will display on their notice boards or other prominent position. It is desirable that members of all branches of engineering, not only electrical, shall be included in the Corps, and the Commandant will be glad to receive applications for enrolment at Marconi House, Strand, W.C. The following is the constitution of the General Committee:—Mr. L. B. Atkinson, Mr. B. Hall-Blyth (President, Inst. Civil Engineers), Lt.-Col. C. B. Clay, V.D. (Commandant), Col. R. E. B. Crompton, C.B., R.E., Mr. E. G. Fleming, Sir John Gavey, C.B., Dr. R. T. Glazebrook, C.B., F.R.S., Major Henrici, R.E., Mr. J. S. Highfield, Prof. Bertram Hopkinson, F.R.S., Sir Alexander Kennedy, F.R.S., Col. A. M. Ogilvie, Lt.-Col. A. E. Le Rossignol, R.E., Mr. P. F. Rowell (Sec., Inst. Electrical Engineers), Mr. Alexander Ross (President-Elect, Institution of Civil Engineers), Dr. Alexander Russell, F.R.S., Capt. H. Riall Sankey, R.E., Mr. C. Sparks (President-Elect, Institution of Electrical Engineers), Sir John Snell (President, Institution of Electrical Engineers, Hon. Commandant), Dr. J. H. T. Tudsbury (Sec., Inst. Civil Engineers), Prof. W. C. Unwin (President, Inst. Mechanical Engineers), and Mr. E. Worthington (Sec., Inst. Mechanical Engineers).

The Ediswan Works.—Mr. F. Carrodus, Science Master of King's College School, Wimbledon, with a party of Students visited the Ponders End Works of the Edison & Swan United Electric Light Co., Ltd., on Thursday, the 29th inst. Both the engineering and "Royal Ediswan" lamp-manufacturing sections were visited.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Before the Royal Society of Arts on Wednesday last week, Mr. C. R. Darling (Lecturer in Physics and Electrical Engineering at the City and Guilds College, Finsbury), gave a lecture on trench telephones. The present war, he said, had been rightly called a telephone war. Since the East began to teach the West, and the Japanese in their war with Russia showed the potentialities of the telephone in large-scale warfare, everyone was aware that in any future war telephones would play a very important part, but probably no one suspected that they would assume the importance they had in the present conflict. Flag-signalling had practically been abolished, and all communications were carried on by telephone. The bell had also been abandoned for calling purposes and the buzzer substituted, for the reason that frequently during the noise of the fighting speech was impossible, but by means of the buzzer communication was maintained by Morse signalling. The buzzer which was most popular for field purposes was known as the D Mark III., which by reason of being constructed with two electro-magnets working in conjunction with a pivoted reed vibrating at both ends gave a clearer note for Morse signalling purposes than the buzzer with a reed vibrating at only one end. Nevertheless, owing to the demand for instruments, many of the latter type of instrument were in use. The total weight of the D Mark III. outfit, including two dry cells and leather case, was 8lb., and as a measure of precaution against interruption it was provided with two receivers, one an ear-piece with strap for fastening round the head of the operator, and the other a combination receiver and transmitter. Dealing with the lines used for field work, the lecturer pointed out that for temporary work a single strand iron wire is used, merely varnished for insulation. This is usually abandoned when communication is no longer needed. For more permanent work a steel wire consisting of several strands was used, with better insulation than in the case of the single-strand iron wire. Steel was used on account of its greater strength compared with copper. Dealing with some of the difficulties in maintaining communication due to wires being broken from various causes, Mr. Darling mentioned some of the devices for mitigating the inconvenience so caused. A good many attempts had been made to devise some system of multiple lines, and one idea introduced by the French is to lay the wires practically in the form of a ladder. In other words, two lines are laid more or less parallel between the transmitting and receiving stations connected across at frequent intervals in the form of rungs. These rungs—the more the better—naturally vary considerably in length, but the object is to maintain communication even if the circuit is broken in several places, and this plan is found to achieve that object, there being practically always at least one path open for the current. Meanwhile, repairs can be carried out. Another plan is to locate a telephonist in a dug-out approximately half-way between the two stations and to carry three or four wires through this dug-out. By continual testing the operator in the dug-out is able to ascertain which line is broken, and by connecting up the sound wires on either side is able to maintain continuous communication whilst repairs are attended to. In conclusion, the lecturer emphasised the great need for a further supply of telephonists for the Front, and also the absolute necessity that such men should be thoroughly trained in the technical side. With this object in view, he suggested that all teachers of physics and electricity should offer their services to the Government, so that a co-ordinated scheme for training men as telephonists could be evolved and an ample supply of trained operators provided. At present the number available was not that which might be desirable.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Bury.—The Corporation proposed to spend £7,500 upon new plant at the electricity works.

Erith.—The scheme of extensions drawn up by the Borough Engineer has been sanctioned by the Council.

Falkirk.—A new sub-station is to be constructed by the Council.

Manchester.—A third converter is to be installed at the London Road sub-station.

Watford.—A loan of £1,560 for mains is to be applied for.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Blackpool.—Mineral water factory. E. Kay.

Bury.—Weaving shed. Elton Cop Dyeing Co.

Cardiff.—New police court, Pontardawe. Clerk, County Hall. August 12th.

Chorley.—Council school.

Derby.—A loan of £4,500 has been sanctioned for extensions to the Free Library and Art Gallery.

Glasgow.—Electrical installation at Govanhill public baths. Town Clerk. August 12th.

Leeds.—New central technical school.

Salford.—Rebuilding warehouse. Davies & Co., Hutchinson Street.

Sheffield.—Extensions City Hospital, Crimicar Lane. City Architect.

Southport.—Hospital. Architects, Bolshaw, Packer, Peach & Prescott.

Swansea.—Hospital (£50,000).

Tonbridge.—Post office (£9,000).

Wigan.—Cinematograph theatre. William Well, King Street.

Miscellaneous

London: *H.M. Office of Works.*—Twelve months' supply of electric incandescent lamps. August 13th. (See an advertisement on another page.)

Manchester.—Arc lighting in Piccadilly.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Leith.—The Corporation has placed a contract with Siemens Bros. Dynamo Works for a twelve months' supply of tantalum and traction lamps.

Redditch.—The following tenders have been received for a H.T. three-phase switchboard in connection with the extension scheme now being carried out under Messrs. Handcock & Dykes:—Bertram Thomas, £1,875 10s. (accepted); Electric Construction Co., £1,892 14s.; British Westinghouse Co., £1,998 14s.; General Electric Co., £2,090; Switchgear & Cowans, £2,191; British Thomson-Houston Co., £2,223 14s.; Ferguson, Pailin & Co., £2,239 14s.; Johnson & Phillips, £2,274 10s.; Edison & Swan Co., £2,297 11s.; Park Royal Engineering Works, £2,400.

Worcester.—The Corporation are to purchase two Erith Riley patent stokers at £775, and an Edison 3-ton battery tipping lorry at £941.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £86 10s. to £87 10s. (last week, £88 to £89).

Agencies.—A firm inquires for the names of United Kingdom manufacturers of dynamos, motor starters, switches, and

lamps, desirous of being represented in Australia.—A firm of iron and steel merchants in Montreal wishes to secure the representation of United Kingdom manufacturers of steel tape to be used in connection with electric cables.—An Italian firm wishes to represent United Kingdom manufacturers of electrical measuring instruments and other electrical apparatus in use in dockyards, on tramways, &c. Further particulars at 78 Basinghall Street, E.C.

Liquidations.—The creditors of the Consolidated Diesel Engine Manufacturers, Ltd., will be paid in full on August 17th at General Buildings, Aldwych, London.

A petition for the compulsory winding up of the Adnil Electric Co., Ltd., will be heard in the Chancery Division of the High Court on October 19th. The petitioners are the Acme Electrical Manufacturing Co., of Tottenham.

APPOINTMENTS AND PERSONAL NOTES

Mr. R. Wright, District Engineer in the Auckland area of the Cleveland & Durham Electric Power Co., has been presented with a case of drawing instruments and a case of pipes on his departure to South America, where he will take up the position of Mains Engineer with the Argentine Railway Co.

On the eve of departure for Australia, Mr. W. A. Holmans, a member of the staff of the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex), for over sixteen years, was presented by the staff with a diamond ring, a cabin trunk, and a pocket-book. Mr. Holmans is to be stationed in the Ediswan showroom at Melbourne.

The names of about 250 of the staff of the County of London Electric Supply Co. and Associated Companies who have joined the Forces, of whom already four have lost their lives for their country, are contained in a Staff War Bulletin, in which some interesting extracts of letters from the Front and other notes are published.

Private A. Hotz, of the Construction Department of the British Thomson-Houston Co., has been decorated with a Distinguished Conduct Medal for conspicuous gallantry on Hill 60, when he placed himself in front of a communication trench occupied by the enemy, and, on the enemy advancing, attacked them with hand grenades and dispersed them.

In June the Nuneaton Council succeeded in persuading their Electrical Engineer, Mr. R. N. Mayne, from joining the Forces on the ground that he was urgently needed to carry through an important scheme of extensions. Last week Mr. Mayne asked for an increase of £150 per annum in salary, but by nine votes to four the Council confirmed a refusal of the Electricity Committee to grant the application.

The late Major Flood-Page, a director of Marconi's Wireless Telegraph Co., left estate valued at £5,671.

Mr. P. H. Fox has been appointed Chief Electrical Engineer at Musselburgh at a commencing salary of £215 per annum.

Mr. H. A. Ratcliffe, head of the testing department of the Manchester electricity undertaking, has been appointed a member of the Manchester Air Pollution Advisory Board.

An electrician is required for a permanent position in London. (See an advertisement on another page.)

LOCAL NOTES

Bristol: Criticism of Electricity Department.—Notwithstanding the satisfactory results of the past year's trading of the electricity undertaking, as reported on p. 326 of our last issue, there is still criticism of the department. At the last meeting of the Corporation, when the accounts were adopted, Councillor Witty described the undertaking as a colossal financial failure, and urged the appointment of an expert to report upon the undertaking. Having failed in this, he has given notice of his intention to move the recission of the resolution adopting the accounts.

Greydon: Satisfactory Year's Working.—The auditors of the Electricity Department's accounts recommend that the net profit of £2,595 on last year's working, together with £2,284 brought forward, be transferred to the reserve and renewals fund.

Glasgow: Cost of Coal.—During the discussions in the House of Commons upon the Government Bill for limiting the

price of coal, several references were made to the extra expense incurred by the Glasgow Corporation upon its coal purchases. These were no doubt inspired by Bailie W. B. Smith, Convener of the Electricity Committee, who, together with other municipal representatives, has been in London for about a fortnight in connection with this matter. The Glasgow Corporation contracts, having been entered into since April 30th, now come within the scope of the Bill, with the result that the Electricity and Gas Departments alone will save some £60,000 of the price they would otherwise have had to pay. The average increase in price was 5s. 3d., whereas under the Bill it cannot be more than 4s. There was a deficit of £459 on last year's working of the electricity undertaking. We have already reported the decision to add 15 per cent. to all accounts.

Manchester: Proposed Investigation Committee.—The agenda for yesterday's meeting of the Corporation contained a notice of motion by Councillor Ross C. Clyne for the appointment of a Special Committee to inquire into the working of the electricity undertaking, this Committee to appoint an independent electrical engineer to advise it. It is also proposed to hear evidence from ratepayers as to their views upon the present policy of the department. The motion seems to point to a continuation of the hitherto abortive efforts to prevent the Barton power scheme being proceeded with during the period of the war.

Southampton: Proposed Increase in Charges.—There have been many discussions regarding charges for some time past, quite irrespective of the war, and it is not altogether surprising that some change should be made. For private lighting consumers the charge for the first 50 units is to be 3½d. per unit instead of 3d., the charge for consumption above that remaining at 2½d. per unit; for business premises the charge is to be increased from 3d. to 3½d. per unit; for supply outside the borough, 3d. instead of 3d.; and for heating and cooking, whether inside or outside the borough, 2d. per unit instead of 1d. A simpler scale than at present in use for power purposes is to be drawn up. No alteration is to be made in public lighting or traction. There was a lively discussion on these proposals at the meeting of the Corporation on Wednesday last week, the Electricity Committee being admittedly not unanimous. There was a section who preferred a 10 per cent. increase all round rather than dealing with each class on its merits. However, the above scheme was eventually adopted, and thus the Point-Five Association loses a member.

Sutton Coldfield: Loan Refusal.—The Local Government Board has refused the loan of £2,500 applied for recently by the Council. The Chairman of the Electricity Committee has drawn up a special report on the matter, which has been forwarded to the Board.

West Ham: Workman's Compensation Claim.—A case has just been decided in the Bow County Court in which a workman in the West Ham Corporation Electricity Department has been awarded £350 in respect of injuries sustained by electric shock whilst cleaning out a transformer sub-station. The hearing of the case occupied three days, and it appears that after the accident the man was paid full wages, 37s. 6d. per week for ten weeks, after which it was suggested he was in a condition to do light work. Evidence was called on his behalf, however, to the effect that he could not carry out work of the character he had been used to, whilst the Corporation called evidence to prove the contrary. Eventually the Court made the award mentioned above.

SUMMARY

MR. ROBERT HAMMOND, the well-known pioneer of electricity supply, died on August 5th after a short illness (p. 336).

SOME notes on the half-watt lamps from a recent issue of the *Elektrotechnische Zeitschrift* indicate the lines of the most recent developments in this connection in Germany (p. 336).

GERMANY's "mobilisation" of copper formed the subject of an article in the *Elektrotechnische Zeitschrift* of July 29th, which we review at some length (p. 337).

A CONTRIBUTION to the *Journal* of the Institution of Electrical Engineers by Mr. N. W. McLachlan describes an investigation into the magnetic behaviour of iron under alternating magnetisation of sinusoidal wave-form (p. 337).

WE outline the programme of the British Association meeting at Manchester in September (p. 337).

A PROBLEM connected with the arrangement of the excitation circuit of D.C. machines is discussed in our Questions and Answers columns (p. 338).

REVIEWS and particulars of recently published technical books appear on p. 339.

AMONG the subjects of specifications published last Thursday at the Patent Office are electrical dust precipitation, metal-filament lamps, electric locomotives, safety appliances, and high-frequency alternators (p. 340).

LONDON electrical wiremen have been granted an increase of 1½d. per hour on wages (p. 340).

THE electrical equipment of a cement works is described in an illustrated article (p. 341).

THE Johannesburg Council requires two 3,000-kw. turbo-alternators; generating plant is required at St. Helens (£15,000); Chesterfield (£15,200); Leyton (£18,158); and Bootle. An installation is required for the Earby Sewage Disposal Works; motor for the Nelson Sewage works, and the bulk supply scheme at Lytham is to be carried through (p. 342).

AN attempt to secure the resignation of the Belfast City Electrical Engineer has failed.—The Waterford scheme is to be postponed.—Several towns are finding themselves short of capital for laying mains; and new loans are not easily forthcoming (p. 342).

A NUMBER of London supply companies have declared interim dividends (p. 343).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING AUGUST 21ST, 1915.
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday, Wednesday, and Friday:—Drills 6.30 and 7.30.

(There will be no drill on Monday, August 14th.)

Applications for Enrolment:—All applications for enrolment should be sent to the Commandant, Marconi House, Strand, from whom all particulars can be obtained.

E. G. FLEMING.

(Company Commander and Acting Adjutant.)

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

The General Committee of this Corps includes the names of many of the prominent members of the three principal branches of engineering, and among them we note the Presidents, and also the Secretaries, of the Institutions of Civil, Mechanical, and Electrical Engineering. The Corps has not only the hearty support of the heads of the engineering profession, but is warmly supported by General Sir O'Moore Creagh, V.C., G.C.B., G.C.S.I., the General advising the Central Association V.T.C.

To enlarge the usefulness of the Corps, further recruits can be accepted either from among the membership of the Institutions or from others who are willing to be trained in fortress engineering work under the staff of the London Electrical Engineers (T.F.) at their Headquarters in Westminster.

The Japanese and Australian Trade.—Attention is called by H.M. Trade Commissioner for Australia to the endeavours which the Japanese are making to capture the trade there in glassware for electrical fittings, insulators, &c., formerly to a large extent controlled by Germany. It is regarded as significant that the Yokohama Specie Bank is about to open a branch at Sydney. There seems to be a strong probability, owing to British firms being engaged in making munitions, that much of the Australian trade hitherto done with enemy countries will meanwhile find its way to countries not directly involved in the war.

OBITUARY

ROBERT HAMMOND.

A VERY well-known figure in the electrical world has been removed by the death, on Thursday, August 5th, of Mr. Robert Hammond, at the age of sixty-five years. It was only about a month ago that he showed signs of illness, but during the past fortnight or three weeks he had been seriously ill with cerebral thrombosis. His death has come as a shock to a very large number of friends, both in the electrical industry and in the political circle, in which he was also well known and esteemed. On the last public occasion that we met him, at the annual meeting of the Institution of Electrical Engineers, he still showed all that virility and animation which were so characteristic of him throughout his career, and there appeared to be no indication then that his health was giving way. The funeral took place at the Golders Green Crematorium on Monday.

Mr. Hammond was, in the fullest meaning of the term, one of the pioneers of the electrical industry in this country, having established himself in it before the passing of the Electric Lighting Act of 1882. Few men can lay claim to such a variety of practice, for in turn he played a conspicuous part in the introduction of the Brush arc machine, in the installation of electric lighting undertakings in numerous places in Great Britain and abroad, in some cases as contractor but in the majority as consulting engineer. His interests extended to tramways, both as consulting engineer for their installation and as arbitrator in fixing charges for current, he was one of the first to moot the possibility of generating electricity on the Rand on a large scale, and he was associated with the first schemes of the London County Council for dealing with the supply of electrical energy in the County of London and surrounding area. He was also retained by the Postmaster-General in connection with the acquisition of the business of the National Telephone Co. His reputation as an expert witness, especially in the Parliamentary Committee Rooms, in connection with municipal electric lighting and tramway schemes, was of the highest. As consulting electrical engineer to municipalities he enjoyed an extremely large practice from the early years of the industry until the day arrived when almost every town of any size had been provided with a supply of electrical energy. Indeed, to this day many of the older-established electricity works are commonly spoken of as "Hammond" stations. A few years ago his son, Mr. R. W. Hammond, was taken into the firm, and the consulting practice was continued under the style of Robert Hammond & Son.

In the early days Robert Hammond was also active in promoting facilities for the training of electrical engineers, first in 1884 at the Hammond College in Hanover Square, a scheme which later developed into the Electrical Standardising Training and Testing Institution (Faraday House), of which he was the founder in 1890. Since 1902 he has been well known to many of our readers as treasurer of the Institution of Electrical Engineers, the financial destinies of which were in his capable hands during the trying period when its new home on the Embankment was being secured. His cheery optimism and ready humour have brightened many an Institution meeting, but it is not so well known that the Institution owes him a deep debt of gratitude for hard and even more useful work on the Council and in Committee.

At the funeral, the following gentlemen represented the Institution of Electrical Engineers:—Sir John Snell (*President*), Messrs. A. Siemens and W. M. Mordey (*Past Presidents*), Messrs. F. Gill and A. M. J. Ogilvie, and Dr. A. Russell (*Members of Council*), Messrs. H. W. Couzens, G. W. Spencer Hawes, F. Ince, J. E. Kingsbury, E. A. Nash, A. H. Preece, J. Rider, H. M. Savers, S. Sharp, A. M. Sillar, A. A. C. Swinton, H. W. Wilkinson, and W. Wyld (*Members*); and

the following wrote regretting inability to attend:—Messrs. W. A. Chamen and R. A. Chattock, Sir William Crookes, Col. R. E. Crompton, Messrs. W. B. Esson, J. S. Highfield, and H. Hirst, Prof. T. Mather, Messrs. S. Morse, G. W. Partridge, W. H. Patchell, H. Faraday Proctor, R. T. Smith, C. H. Wordingham, and P. F. Rowell (*Secretary*).

The death occurred recently of Mr. J. C. Gill, Electrical Engineer to the City of Peterborough.

SOME NOTES ON HALF-WATT LAMPS

THE *Elektrotechnische Zeitschrift* of July 22nd, 1915, contains some notes on the behaviour of half-watt lamps by Dr. K. Mey, of the A.E.G. He points out first that it requires more energy to bring a filament to the same temperature in nitrogen than *in vacuo*, so that the better efficiency is only attained by using a much higher temperature. The filament burns out, however, owing to rapid vaporisation unless it is spiralled or arranged in some other way to occupy only a small space so as to limit its capacity of giving off heat to the gas, when only a moderate increase in temperature is necessary to make up for the loss of heat; and it is found that the permissible rise in temperature corresponds to a lamp efficiency of 0·65 watt per mean spherical Hefner c.p. A 110-volt Hefner c.p. lamp has a filament spiral about 145 mm. long and 0·62 mm. diameter, and emits 10·7 Hefner c.p. per sq. mm. surface, and the gas in it is at two-thirds atmospheric pressure. The efficiency based on the mean hemispherical candle-power (without lantern or reflector) is 0·5 watts per Hefner c.p., and it is estimated that the loss of about 7 per cent. by obscuring the globe is just about compensated for by the use of an outside reflector.

In the article an interesting curve is given to show the dependency of candle-power and efficiency on voltage, and it appears that the variation is in about the same proportion as that of an ordinary tungsten lamp. A 5 per cent. drop in voltage reduces the candle-power by about 15 per cent., but the watts per candle only increases from 0·5 to 0·55. A 5 per cent. increase in voltage sends the candle-power up about 20 per cent., and reduces the watts per candle to about 0·45. At 10 per cent. below normal voltage the candle-power is still nearly 75 per cent. of the normal, and the watts per c.p. about 0·62.

Results of oscillograph experiments to ascertain the current rush on switching on are also given. The momentary current is eight to nine times the steady current, as the resistance of the filament when cold is 1/10th that when hot. The maximum value of the current lasts less than 1/100th of a second, however, and the current drops to normal in 1/5th second. These figures seem to be more or less of the same order as with ordinary tungsten lamps.

The same issue of the *E.T.Z.* contains, in its advertisement columns, a complete list of 100–130 and 200–250 half-watt lamps of a well-known German make; the range is the same for both voltages, there being seven sizes between 150-watt and 1,500-watt inclusive, but the candle-powers vary. Both mean spherical and horizontal candle-powers are given. In no case does the former reach $\frac{1}{2}$ watt per c.p., and the horizontal c.p. only reaches $\frac{1}{2}$ watt per c.p. (Hefner) in the larger sizes. The 150-watt 100-volt lamp has a horizontal c.p. of 240 Hefner, and the 200-volt lamp of the same wattage only 200 Hefner, i.e., 0·75 watt per Hefner c.p.

A State Research Council.—The Board of Education has issued particulars of its scheme for the organisation and development of scientific and industrial research which was discussed some time ago in the House of Commons in connection with the Educational estimates. The scheme is to have a permanent organisation of a national character which will have complete liberty to utilise the most effective institutions and investigators available. For this purpose there is to be established a Committee of the Privy Council responsible for the expenditure necessary and a small Advisory Council consisting of scientific men and men actually engaged in industries dependent upon scientific research. The Committee will consist of the Lord President, the Chancellor of the Exchequer, the Secretary for Scotland, the President of the Board of Trade, the President of the Board of Education, the Chief Secretary for Ireland, and any others whom it may be thought desirable to add. The first non-official members of the Council will be Lord Haldane, Mr. A. D. Acland, and Mr. J. A. Pease, M.P. The first members of the Advisory Council will be Lord Rayleigh, F.R.S., Dr. G. T. Beilby, F.R.S., Mr. W. Duddell, F.R.S., Prof. B. Hopkinson, F.R.S., Prof. J. A. McClelland, F.R.S., Prof. R. Meldola, F.R.S., Mr. R. Threlfall, F.R.S., and Sir William McCormick, who will be Administrative Chairman.

GERMANY'S "MOBILISATION" OF COPPER

WE have before us an authoritative article recently published in Germany on the present position of that country as regards copper supply. It is a broad review of the situation, by a writer evidently possessing a good technical knowledge and more or less accurate information on the subject upon which he writes, and no attempt is made to minimise the great inconvenience which has already been caused by the German Government having taken possession of all stocks of raw and partly-manufactured copper for the Army. It is also admitted that the public must be prepared for more drastic measures in this respect; but one thing stands out clearly and must be noted for the benefit of optimists who persist in construing every move taken by Germany as a sign of an almost immediate collapse. *There is copper in Germany sufficient for Army requirements for years and not merely for months; it is true that the "mobilisation" of the metal will continue to cause the civil population some inconvenience, but it is equally apparent that, unless the war lasts many years, shortage of copper will not, as has been predicted in some quarters, be a determining influence in bringing the war to a conclusion.*

The article, which was published in the "Elektrotechnische Zeitschrift" of July 29th under the title "The Mobilisation of Copper," after referring to the requisition by the Army, as already mentioned, of all raw and partly-manufactured copper available, estimates the stock of manufactured copper "in the hands of the public" at two million tons. The term "in the hands of the public" is perhaps not quite a happy one for strict accuracy, for a considerable proportion of this stock is in the form of copper roofing on public buildings, etc., which is a feature of German architecture. How soon this stock will be drawn upon is not stated, but the German War Office has already instituted an Office for Metal Mobilisation, which on July 20th issued an order for a register to be made of the copper held by certain sections of the public (including electricity and other works) as represented by a large range of manufactured articles, both new and old, consisting wholly or partly of unalloyed copper, including tinned copper, and copper covered with a coating of other metal or paint. A form has been issued to enable the register to be made, and its return is compulsory; there is a column in it in which voluntary offers of copper for sale may be filled in, and the article in our contemporary makes an appeal to copper users to do all they can in this direction, so as to ward off a general calling-up of manufactured copper articles.

The writer of the article suggests, in the first place, the replacement of all overhead copper wires by zinc or iron wires, but admits that a difficulty will arise in many cases owing to the fact that the existing poles, insulators, etc., may not be strong enough to carry the requisite heavier weight of these substitutes. To overcome this he proposes that larger voltage drop in the lines should be allowed, and this would enable the copper lines to be replaced with others of smaller section even if the substitution of them by iron wires is not found feasible. This leads him to the suggestion that higher transmission voltages should be resorted to wherever possible, as the copper required for the transformers would be inconsiderable compared with that saved on the line, and he goes further and advises that, to make a virtue of necessity, numbers of the older electric light and power systems should be modernised. Towns still supplied on the low tension direct current system with long feeders of large section might with advantage, he says, have their systems converted to three-phase high pressure transmission with rotary sub-stations at the feeding points, but he does not insist upon these drastic measures being taken immediately. In Germany, as in this country, there are large numbers of reciprocating sets standing comparatively idle as "reserve plant" in electricity works in which the load is regularly taken by modern turbine machines. The amount of copper in these per kw. output is of course far greater than in the turbo-generators, and he invites serious consideration of the "slaughter" of these innocents in the service of the Fatherland. Finally, the writer even goes so far as to suggest the reconstruction of many of the older transformers, to utilise the newer iron alloys for their cores, and so to diminish the proportionate weight of copper.

Obviously some of these measures are extreme ones—some, indeed, hardly merit serious thought. It must not be inferred, however, that this implies an immediate copper famine, any more than the issue of bread tickets in Germany months ago presaged an immediate bread famine. There has been sufficient evidence during the past year of the useful German habit of looking forward and methodically providing for any emergency, and the moral to be drawn from such articles as the one now reviewed is that, although Germany is provided for a long time to come with sufficient copper

for war requirements, yet she is prepared to adopt heroic measures for providing further supplies should emergency arise. The author of the article, in fact, uses the argument that, although it may be long before the more easily acquired stocks of copper will be exhausted, yet the modifications in existing conditions which he outlines will also take long to carry out, and that therefore it is not too early to give consideration to them.

MAGNETISATION OF IRON BY AN ALTERNATING FIELD

A CONTRIBUTION to the *Journal of the Institution of Electrical Engineers* describes an investigation by Mr. H. W. McLachlan into the behaviour of iron under magnetisation of sinusoidal wave-form. First of all, the effect of bending the samples to form test rings was investigated by comparing a bent-up ring with one composed of stamping, and it was found that the bending of thin plates of "Lohys," resulting in permanent set, does not affect the magnetic properties to any appreciable extent when the magnetisation is produced by a steady current. The permeability is lower at small flux densities, this being due to the joints in the strips whereby slight air-gaps are introduced. The permeability is affected in the same way when the magnetisation is produced by an alternating current of sinusoidal wave-form. In this case there is an increase in the hysteresis due to mechanical stress.

The main experiments lead to the following results:—When the magnetisation is produced by an alternating current of sinusoidal wave-form the permeability is greater than with static fields. This phenomenon was observed from maximum flux densities from 700 to 16,000 lines per sq. cm. For all values of the flux density in the iron up to 16,000 lines per sq. cm. the form factor and the ratio of the maximum and R.M.S. voltages are greater than the corresponding quantities when the voltage wave-form is sinusoidal, by an amount depending on and increasing with the maximum flux density. The R.M.S. and maximum values of the voltage are larger than those obtained when the voltage wave is sinusoidal by an amount depending on and increasing with the maximum flux density. For frequencies up to 500 periods per second the R.M.S. voltage is higher than that when the voltage wave is sinusoidal, but the lowering of the maximum flux density due to eddy currents is very prominent. When the magnetisation is produced by a current the wave-form of which is approximately sinusoidal, the above conclusions are applicable. The difference between these results and those obtained when the voltage wave is sinusoidal is not so marked as the difference between the latter results and those obtained when the current is sinusoidal. Whether the current be sinusoidal or approximately sinusoidal, the R.M.S. voltage across the secondary coil is proportionately higher at 25 periods per second than at 50 periods per second for a given magnetising current.

THE BRITISH ASSOCIATION

THE programme of the meeting of the British Association which is to be held at Manchester from Sept. 7th to 11th, under the Presidency of Prof. Arthur Schuster, has been issued. As already announced, the meeting this year will be devoted exclusively to the technical work, the whole of the usual social programme having been eliminated.

The sectional meetings have been arranged as usual, Section G (Engineering) having for its President, Dr. H. S. Hele Shaw, F.R.S. The following are the electrical papers to be read in this section: "The Heating of Iron when Magnetised at Very High Frequencies," by N. W. McLachlan; "Some Experiments to Determine whether there Exists Mutual Induction between Masses," by Prof. Miles Walker; "The Eddy Current Losses in the End Plates of Large Turbo-Generators," by Prof. Miles Walker; "Electric Oscillations in Coupled Circuits—a Class of Particular Cases," by Dr. W. H. Eccles and Mr. A. J. Makower; "The Capacity of Aerials of the Umbrella Type," by Prof. G. W. O. Howe; "The Calculation of the Effect of Masts and Buildings on the Capacity of Aerials," by Prof. G. W. O. Howe.

A number of matters in other sections may also be mentioned. In Section B (Chemistry) there will be a discussion on "Smoke Prevention," and in Section L (Educational Science) a discussion will take place on "Education and Industry." A report of the Committee on Industrial Fatigue, to be presented to Section F (Economic Science and Statistics), may also produce some points of interest, whilst a discussion in the same section on the production of industrial harmony will attract attention having regard to recent happenings in the labour world.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,455.

Is it usual to make the air-gap length of large D.C. and A.C. motors and generators equidistant under all poles of a given machine, or is the gap less under the top poles? If the latter is the case, why is it done? How much is this reduction for various sizes and types of machine, and what calculation is this reduction based upon? What method is employed to set the machine out of centre?

(Replies must be received not later than first post, Thursday, August 19th.)

ANSWERS TO No. 1,453.

Is it practicable, and are there any circumstances in which it is advantageous, to take the excitation circuit of a 4-pole dynamo from one pair of brush arms while the other pair is used only for the load?

The first award (10s.) is given to "H." for the following reply:—

For a standard type of dynamo there is no advantage in making the connections as suggested in the question; in fact, in some cases the arrangement is impracticable. It must be remembered that armatures are almost invariably either wave (series) or lap (parallel) wound. In a wave-wound armature of a multipolar dynamo there are only two circuits; in other words, the current per conductor is half the total current from the machine. The current from such a winding can therefore be collected by a pair of brush-arms, but in order to shorten the length of the commutator (the brush width and current density being maintained constant), another pair of brush-arms is provided. The positive and negative brushes of the second pair are really connected to the corresponding brushes of the first pair by armature conductors which in that particular position have no E.M.F.'s induced in them. It should now be clear that the arrangement referred to in the question would require the commutator to be almost doubled in length, while the excitation circuit would really be connected across the same voltage as the load. The effect would be to increase the cost of the machine without any advantage being derived.

In a 4-pole lap-wound armature fitted with four sets of brushes there are four circuits in parallel. Consequently, if the load is taken off only one pair of brushes, the current in the armature conductors is unsymmetrical; in fact, a fourth of the conductors will be carrying three times the current in the other conductors. This distribution of the currents results in the magnetic forces between the armature and the various poles being unequal; also the output (as determined by the heating of the armature) is limited to about a third of its normal value, whilst the voltage for excitation is practically the same as that across the load. The arrangement in question would consequently be impracticable in the case of a lap-wound armature.

For some applications, such as train lighting, all sorts of

arrangements have been tried from time to time, but a consideration of these would be out of place here. Suffice it to say that in such cases either the armature is specially wound or auxiliary brushes are employed with or without split-poles.

The second award (5s.) is made to "N. C. W." who writes as follows:—

The solution to this question involves a consideration of the type of armature windings. These may be broadly classified as "wave" and "lap." In the wave winding there are only two paths through the armature, and only two sets of brushes are essential, though it is customary in dynamos of any large size to supply one set of brushes per pole. In a 4-pole wave-wound machine with four sets of brushes, the two positive brushes are connected through the commutator by inductors generating no E.M.F. Provided that one set of brushes is of sufficient section for carrying the load current, one pair may be reserved for feeding the excitation circuit. The disposition of the leads to the mains and field magnet coils may make this arrangement advantageous by saving a certain amount of cross-connecting wire; on the other hand, it will be impracticable to raise any one set of brushes for cleaning or adjusting purposes while running, as may be readily done when the two pairs are externally cross-connected in the usual manner. A slightly higher E.M.F. may, however, be secured, since the drop of potential in the independent magnet connections to the commutator will be less than when the same brushes carry the main current.

Lap windings are generally employed for lower pressures and larger currents; they have as many paths through the armature as there are poles, and these being all in parallel the total current should be evenly distributed between them. For this purpose all brushes of the same polarity should be heavily cross-connected, it being most important that these be maintained at the same potential, otherwise an irregular distribution of load current in the armature will result, promoting sparking and attendant difficulties. For a lap winding, therefore, the proposal cannot be recommended.

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE next session of the Engineering Department of the University of Edinburgh will open on October 12th, and the entrance examination for new students will be held in September. The complete three years' course in electrical engineering qualifies for the degree of B.Sc. Particulars can be obtained from the matriculation office.

The date of the entrance examination of the City and Guilds (Engineering) College, South Kensington, has been altered from September 21st to September 22nd.

The South-Western Polytechnic (Manresa Road, Chelsea) will reopen on Sept. 27th for day and evening classes. The Engineering Courses include lectures in Electrical and Mechanical Engineering, Physics, Chemistry and Mathematics, and practical instruction in the laboratories. Students are prepared by recognised teachers of the University of London for the B.Sc. Degree in Engineering, for the examinations at the Engineering Societies, and of the City and Guilds of London Institute. The evening courses also include classes in electrical wiring and other trade subjects. In the Electric Wiring Department an advanced course has been arranged for the preparation of candidates for the Final Wiremen's Examination of the City and Guilds of London Institute. Arrangements have been made for placing students who have passed satisfactorily through the three years' day course in positions with large engineering firms, and hitherto such firms have offered more vacancies than the Institute has been able to fill with its students. The Prospectus may be obtained on application to the Secretary, Electrical Engineering Training.

Generating Station Damaged by Fire.—On Sunday of last week a serious fire occurred in the power station of the Ebbw Vale Steel, Iron, and Coal Co., at Victoria, South Wales, and despite the effort of the local fire brigades, the generating plant, much of which is practically new, was badly damaged. We understand, however, that the newspaper reports were considerably exaggerated, and that the damage done was principally to accessories. Owing to the cessation of the power supply, a large proportion of the steel mills and other works were stopped, and a colliery was rendered idle, throwing some thousands of men out of work. The whole of the works and collieries had fully resumed work on Monday. The station also supplied lighting to the town, which was put in darkness.

REVIEWS OF BOOKS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

Electric Light Fitting. By S. C. Batstone. 317 pp. 7½ in. by 5 in. 238 figures. (London: Whittaker & Co.) 5s. net; abroad, 5s. 5d.

On turning over the leaves of this book one receives a first impression of completeness and practical value. Examples of the lay-out of actual installations are given with plans of buildings, several good drawings of accessories are included, and there is a chapter on private plants which actually goes into such detail as the calculation of loss of head in a water-power plant, due to pipe friction. On examining the matter more closely, however, it becomes apparent that its value is greatly impaired by almost unparable carelessness. Thus, although Ohm's law is explained with the help of a pump and pipe analogy, we cannot find any definite instructions how to apply this law to the practical calculations of voltage drop in a cable; in the reference to alternating currents, the reader is told that the impedance of a circuit is equal to inductance plus ohmic resistance, and that the square of the impressed volts is equal to the sum of the squares of the inductance and the ohmic resistance; the description of the calculation of loss of head in pipes, already referred to, is almost unintelligible; and the illustration of a steel-wire armoured cable shows a braided cable surrounded by a single galvanised iron wire wound round it in an open helix like an armoured hose-pipe.

The drawings are for the most part excellently done, but some of them represent an unnecessary waste of space. It would seem to be unnecessary to explain what is meant by a "polished teak main switchcase with glass front, lock and key" by means of a drawing; the only value in this might be to indicate the clearance which it is advisable to leave between the switch and the case, but the switch itself is not shown, although the fact that the key has been forgotten shows that the author is alive to practical conditions. Other drawings show ordinary switches and lampholders in great detail, and even candle-shades; an illustration of the familiar well-glass fitting is carefully lettered to show which is the tube and which the well-glass, but the practical tip of using rubber rings on both sides of the lip of the well-glass is not considered worthy of mention; and there is a picture of the dear old scarfed joint in a stranded conductor, which has, we are sure, never been made by any wireman in the present century. In one of the conductor tables, the "safe" currents are calculated on the basis of 1,000 amperes per square inch, and in another the I.E.E. ratings are given; it is a matter of almost daily occurrence to decide whether a 5-ampere radiator may be connected on a 3/22 circuit, and the reader is left in the quandary that one end of the book says that 1·8 amperes is the safe current, and the other end of the book gives it as 7·2 amperes.

Notwithstanding the defects in the book, it is obvious that the author possesses knowledge and experience in his subject, and from the drawings it is clear that he is a man who can take pains. Should a second edition ever become necessary, we hope that he will do himself better justice.

Electric Bells, Alarms, and Signalling Systems. By H. G. White. 84 pp. 7 in. by 4½ in. 57 figures. (London: S. Rentell & Co., Ltd.) 1s. 6d. net; by post, 1s. 8d.

The collection of diagrams should save the bell installer considerable time, but the author has not made the most of his opportunity. Valuable assistance might have been given in the way of more specific guidance as to the number and size of cells to be selected for installations of various character and extent, and far more than the adoption of a correct diagram of connections is necessary in designing the more complicated hotel installations. The author, moreover, is not correct in his assumption that single stroke bells are employed for little else than railway and mining work; within almost a stone's-throw of his publishers' offices there has been for several years an installation of these in use, the proper maintenance of which may literally be a question of life or death. It is true that the employment of single-stroke bells for signalling purposes in public institutions has not been developed to the extent it deserves, but in some quarters considerable attention has had to be devoted to the efficient arrangement of such installations. One of the questions that constantly arises in the very simplest of bell installations has been neglected by the author, although a chapter is devoted to maintenance work: Not one bell-fitter in ten knows the weight of sal-ammoniac, which should be used in a Leclanché cell of each of the three sizes. It is not improbable

that tons of this material are lying wasted at the bottom of cells all over the country, serving no purpose but to augment the trouble due to "creeping" and to hasten the corrosion of the zincs and connections. A book with the title of the present volume should also discuss the relative merits of wet and dry cells and the applicability of each. Finally, mention may be made of a chapter on mine signalling, which includes descriptions of various systems on the market.

NEW PUBLICATIONS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

"Wiring of Finished Buildings." By T. Croft. 275 pp. 8½ in. by 5½ in. 205 figures. (New York: McGraw-Hill Book Co.; London: Hill Publishing Co., Ltd.) 8s. 4d. net.

"Advanced Theory of Electricity and Magnetism." By W. S. Franklin and B. MacNutt. 300 pp. 8½ in. by 5½ in. About 260 figures. (New York: Macmillan Co.; London: Macmillan & Co., Ltd.) 8s. 6d. net; abroad, 9s. 1d.

"Labour Unrest: War-time Thoughts on a National Danger." By G. E. Toogood. 78 pp. 7½ in. by 4½ in. (London: A. Brown & Sons, Ltd.) 6d. net; by post, 7½d.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 5th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

27,059 and 27,060/13. Dust Precipitation. G. A. KRAUSE. The first of these describes a method of separating dust particles from gases or air by passage of the gas to be treated through a chamber equipped with two sets of "collecting" electrodes of like polarity, while the "charging" electrodes (of opposite polarity to the collecting electrodes) are in a separate chamber through which the gas passes first. (Two figures.) The second specification deals with the use of rectified A.C. of very high potential, with a multiple spark-gap in the circuit for dust precipitation. (One figure.)

27,157/13. Metal Filament Lamps. G. LÜDECKE and BRIMSDOWN LAMP WORKS, LTD. Supports for filaments made of wires or other structures of an alloy of nickel with 50 per cent. of tungsten.

29,946/13. Wireless Telegraphy. VON ARCO and MEISSNER. A system of wireless telegraph transmission in which the oscillations are produced without dischargers, &c., by an alternator of moderately high frequency in conjunction with a special arrangement of frequency raising, partly separately excited, transistors, and resistances. The system is described in considerable detail in the specification, and there are no less than 29 claims. (25 figures.)

963/14. Electric Locomotives. K. VON KANDO. A method of driving in which the motors are connected through gearing with an intermediate shaft provided with cranks connected by coupling rods with the driving wheels. The motors are mounted on the frame through resilient supports. (Two figures.)

1,056/14. Incandescent Lamps. B.T.-H. Co. (A.E.G.). A leading wire composed of materials having different coefficients of expansion made so that the relative proportions of the two materials vary within a short range, so that at one point at least the compound wire has the same coefficient of expansion as glass. (Two figures.)

16,111/14. Safety Appliance. J. G. CONWAY. A man working near high-tension conductors is protected from liability to shock by gloves covered with wire gauze and connected through a harness of conducting straps to metal heel plates in the boots. (Four figures.)

17,331/14. High-frequency Alternator. A. HEYLAND. A high-frequency alternator with a salient pole field system and an armature, the iron surface of which forms segments which necessarily bridge the pole-tips of opposite polarity under different phases. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: MEIROWSKY & CO. and MEIROWSKY [Insulating materials] 11,112/14; LONGBOTTOM and FARRAR [Conduit joints] 17,437/14; BRIT. INS. & HELSBY CABLES, LTD., and BROTHERTON [Cables] 4,761/15.

DYNAMOS, MOTORS AND TRANSFORMERS: B.T.-H. CO. and HASTINGS [Motor control] 17,894/14; LEIGH and OSBORN [Means of obtaining high starting torque] 121/15.

Electrometallurgy and Electrochemistry: DEUTSCHE GOLD & SILBER-SCHELDE-ANSTALT VORM. RÖSSLER [Electrolytic production of alkali metals] 10,193/14; BATTLE [Electrolytic metal cleaning and recovery of tin] 14,513 and 14,514/14; OZIL [Electro-deposition] 16,776/14; EVANS (Elektrochemische Werke Ges.) [Furnace electrodes] 17,425/14 and [Method of producing a flow in molten masses and a furnace] 17,426/14.

Heating and Cooking: COLLINS & COLLINS [Heating apparatus] 17,391/14.

Ignition: BELLAMY [H.T. ignition] 15,758/14; T. CROSBY &

SONS and McGREGOR [Sparkling plugs] 19,886/14; VAN RADEN [Sparkling plugs] 3,715/15.

Incandescent Lamps: GILL (Wolfram Lampen A.G.) [Incandescent lamps] 29,981/13; HUGHES [Filaments] 17,332/13.

Instruments and Meters: H. ARON ELEKTRICITATSZAHLERFABRIK GES. [Prepayment meters] 10,417/14; SIEMENS & HALSKE A.G. [Time recorders] 10,477/14; B.T.-H. CO. (G.E. CO., U.S.A.) [Measuring instruments] 17,317/14; EVANS (A.E.G.) [Protection of meters] 17,424/14.

Storage Batteries: R. BOSCH [Battery terminals] 10,478/14.

Switchgear, Fuses and Fittings: WATERS [Protective systems] 23,449/13; IGRANIO ELECTRIC CO. (Cutler-Hammer Mfg. Co.) [Contacts] 20,133/14.

Telephony and Telegraphy: DR. ERICH F. HUTH GES. [Spark gaps] 28,369/13; SIEMENS BROS. & CO. (Siemens & Halske A.G.) [Automatic telephones] 29,833/13; SIEMENS BROS. & CO. and BAKER [Telephones] 11,052/14; VON LEPPE [Production of oscillations] 11,102/14; SIEMENS BROS. & CO. (Siemens & Halske A.G.) [Telephone circuits] 11,212/14; INTERNATIONAL ELECTRIC CO. (A.G. Mix & Genest) [Telephones] 14,798/14; FORRESTER (International Callophone Corporation) [Loud-speaking telephones] 21,921/14 and 8,561/15; SIEMENS-SCHUCKERTWERKE GES. [Stray wave protective devices for wireless telegraphy] 831/15; WESTERN ELECTRIC CO. (W.E. CO., U.S.A.) [Wave amplifier] 275/15.

Traction: FRANK [Track circuit apparatus] 29,665/13; WIRTH [Train control] 29,689/13; SIEMENS-SCHUCKERTWERKE GES. [Means of pulling off overhead conductors] 30,045/13; BRAIN and HODGSON [Signalling] 16,696/14; BELFIELD (Doyle & Hedley) [Couplings] 20,871/14.

Miscellaneous: KRAUSHAAR [Electric miners' lamp] 134/14; ROSSOW [Protection of miners' lamps] 10,674/14; ÖSTERREICHISCHE SIEMENS-SCHUCKERTWERKE & REGAL PATENTE GES. [Electrical Jacquard apparatus] 11,408 and 11,410/14; OTTO [Rectifier] 11,561/14; BIGGIN ["Galvanic" boots] 16,962/14; KAHLAN (Yapolsky) [Light sensitive apparatus] 17,131/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

DYNAMOS, MOTORS, &c.: BRITISH WESTINGHOUSE ELECT. & MFG. CO. [Supply to D.C. motors] 10,131/15.

Switchgear: BRITISH WESTINGHOUSE ELECT. & MFG. CO. [Circuit breakers] 10,130/15.

Telephony: AKTIESELSKABET ELEKTRISK BUREAU [Automatic telephones] 10,050/15.

Traction: KETTERING [Engine starters] 7,758/15; ÖSTERREICHISCHE DAIMLER MOTOREN A.G. [Electrical change speed gear] 9,682/15.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS, AND TRANSFORMERS: D. BALACHOWSKY [Dynamo and motor control] 9,157/07.

Electrochemistry and Electrometallurgy: A. J. PETERSSON [Furnaces] 9,164/06; A. E. EDWARDS (Hille & Müller) [Electroplating] 9,435/06; J. R. WILLIAMS, H. W. BRADLEY, and B. BRADLEY [Electrocatalysis] 9,796/09.

Switchgear, Fuses, and Fittings: H. L. DIXON [Fuses] 8,883/03.

Telephony and Telegraphy: F. RITCHIE [Telautographs] 9,009/07; T. MCKENNA (General Acoustic Co.) [Telephone systems] 9,350/09.

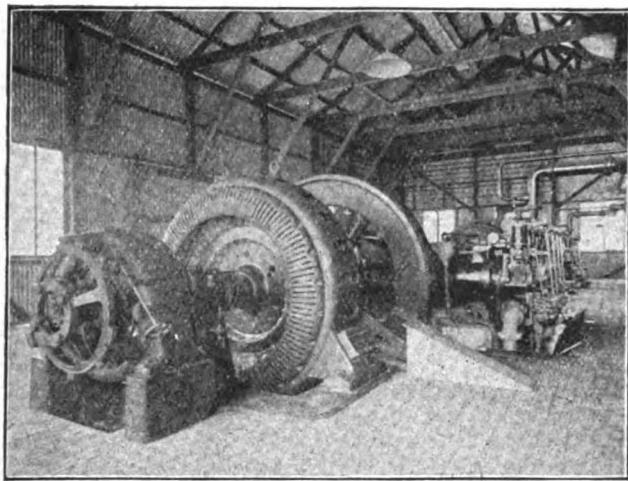

Traction: C. DE KANDO [Overhead conductors] 9,341/06.

Miscellaneous: I. H. PARSONS [Bells, indicators, &c.] 9,324/03.

London Wiremen's Wages.—Although on the outbreak of war the dispute between the London wiring contractors and their men was ended by the men accepting the masters' offer of 10½d. per hour, there has since been negotiations with respect to a request for a further increase, owing to the increased cost of living due to the war. The matter, we understand, finally went to arbitration, and it is believed, although the award has not yet been issued, that the men have been granted a further 1½d. per hour, making the London rate 1s. per hour.

ELECTRICAL DRIVING IN CEMENT WORKS

THE extensive application of electricity for driving cement works machinery applies to the Overseas Dominions just as much as to this country. A recent installation of electrical plant for this purpose is that of the Adelaide Cement Co., of Adelaide, N.S.W. Gas engines were selected for the prime movers, the installation consisting of two 380-h.p. four-cylinder horizontal gas engines, running at 214 r.p.m., and manufactured by the Premier Gas Engine Co. (Sandiacre, near Nottingham), coupled to 275-k.v.a. "Witton" alternators supplied by the British General Electric Co., Ltd., of Sydney, and constructed at Witton, Birmingham, England. The gas producers were manufactured in South Australia by Messrs. Clutterbuck Bros. from designs prepared by their consulting engineer, Mr. W. S. Saunders. Power is supplied to the works motors at 440 volts, 50 cycles, and the generators are designed for a power factor of 0·725. There are several interesting features about this installation. In the first

POWER HOUSE OF THE ADELAIDE CEMENT CO., CONTAINING TWO 275 KV.A. "PREMIER" GAS ENGINES DRIVING "WITTON" ALTERNATORS.

place, good parallel running has been successfully obtained, and the two units run in parallel without the slightest trouble. This is said to be the only plant in Australia in which three-phase gas-driven alternators are run in parallel. Not only do the sets run satisfactorily in parallel at no load as well as full load, but they run well when one of the cylinders is cut out. A second point of interest is the low fuel consumption. On the official tests the weight of fuel consumed per kw.-hour was 1,221 lb., the fuel used being gas-coke. This performance was nearly 25 per cent. better than the guarantee. With regard to governing, during the official tests full load was thrown off the engines and then switched on again; in both cases the engines showed no appreciable variation of speed. The electrical side of the contract was arranged and the plant installed under the supervision of Messrs. Colton, Palmer & Preston, who are the Adelaide agents of the British General Electric Co., Ltd.

Triple Frequency Harmonics.—An interesting example of the effect of triple frequency currents in a mesh-connected alternator is recorded in the *Electrical World*. It appears that the windings of a 750 kw. alternator in a generating plant at Indianapolis were changed from star to mesh, when it was found that the machine ran best even on open circuit. Further investigation disclosed the fact that when the machine was developing full normal voltage on open circuit there was being circulated in the delta-connected windings a current equal to 125 per cent. of full-load current. The delta circuit was opened, and an ammeter and a fixed inductance were inserted into a voltmeter around the inductance. After taking simultaneous readings of the current through the inductance and the voltage drop around it, the engineers making the test placed the same inductance and the same instruments in a sixty-cycle circuit, passing the same value of current through the inductance that had flowed through it when it was connected in the delta winding. Reading the voltage drop around the inductance as it carried this current value in the sixty-cycle circuit, the investigators found the drop to be just one-third that which had been registered with the inductance in series with the delta. From this it was deduced that the frequency of the harmonics in the delta must have been three times the frequency of the sixty-cycle circuit.

CATALOGUES, PAMPHLETS, &c., RECEIVED

POSTER STAMPS.—A very effective series of coloured "poster stamps," calling attention to street pillars, terminal boxes, joint-box compounds, colliery boxes, service cut-outs, &c., has been issued by W. T. Henley's Telegraph Works Co., Ltd. (Blomfield Street, London Wall, E.C.), and form an attractive way of advertising these articles.

CANDLE LAMPS.—The Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex, and 123-125 Queen Victoria Street, E.C.) have issued a revised pamphlet describing their well-known "Kinglite" electric candle. This has a special shaded lamp illuminating the upper part of the opal tube with a charming effect, and has the great advantage over some other candle fittings that a locking ring screwed tightly down on the socket keeps the candle firmly fixed in a vertical position.

CIRCUIT-BREAKERS.—Another new list from the Edison & Swan Co. deals with circuit-breakers for continuous current of the free handle type with main and auxiliary contacts and magnetic blow-out, which can be provided with time-limit feature and overload, reverse current or no-voltage, or combined overload and reverse current release. These are made in a large range of sizes in both the open and enclosed patterns.

STAR-DELTA STARTERS.—A series of standard sizes of air-break star-delta starters for squirrel-cage induction motors up to 25 h.p. are described in a new price list from the British Thomson-Houston Co., Ltd. (Rugby). These are provided with an automatic stop which ensures the lever being held in the starting position sufficiently long for the motor to come up to speed, and can be fitted with no-voltage release and overload protection.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

ELECTRO-GALVANISING.—A leaflet from S. Cowper-Coles (1 and 2 Old Pye Street, Westminster, S.W.) describes the Cowper-Coles electro-galvanising process, in which a particularly even coating of zinc can be electrolytically deposited on any kind of iron and steel work.

LEAD COATING.—The Homogeneous Lead Coating Co. (Sunbury-on-Thames) have sent us a leaflet calling attention to their process of applying a welded lead protective coating to iron and steel surfaces.

METAL FILAMENT LAMPS.—We have received from the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), a copy of their latest revised list of Mazda wire-drawn lamps of standard sizes up to 400 watts for ordinary voltages, and including candle, tubular, sign, and traction lamps. All these lamps are made in the company's works at Rugby.

RESISTANCE NETS.—A card from the Cressall Manufacturing Co. (40 and 41 Staniforth Street, Birmingham) calls attention to various forms of woven asbestos and wire resistance nets for heating, motor control, and other purposes, manufactured by the company at Birmingham. A small sample showing the nature of these nets is attached to the card.

WEIGHT AND CURRENCY COMPUTER.—A leaflet from F. Seaton-Snowdon (22 Henrietta Street, Covent Garden, W.C.) gives particulars of an ingenious instrument, resembling a date indicator with a strip wound up by rollers, for converting foreign weights, measures, and moneys. The headings of British, French, Russian, Scandinavian, Japanese, and American prices per unit weight and measure are set out on the left, and the values that appear on the strip through the window at the same time are all equivalent.

A.C. MOTORS.—A revised price list of single-phase, two-phase, and three-phase induction motors of the slip-ring and squirrel-cage types has been issued by the Langdon-Davies Motor Co. (110 Cannon Street, E.C.). A considerable range of sizes, voltages, speeds, and frequencies are listed, and prices of starters and other accessories are included.

Effect of the War on Electricity Supply in Switzerland.—Owing to the large number of men in mobilisation, many manufacturing works are uncertain as to their output, and strong pressure has been brought to bear upon the electric power supply companies to waive the clauses in agreements relating to the minimum amount of electrical energy to be consumed. In Lucerne, an interesting step has been taken in view of the shortage of lamp oil. To facilitate the replacement of oil lamps by electric light, the municipality (which owns the electricity works) is putting in services free up to a value of £6, and is accepting payment for the installation in monthly or quarterly instalments spread over four years.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Bootle.—Extensions of plant are contemplated to meet the increasing demand and also to replace the Pine Grove Works.

Chesterfield.—A scheme of extensions, estimated to cost £15,200, has been drawn up. It includes a 2,000 kw. turbo-alternator, switchboard, cables, crane, superheaters, and mechanical stokers for existing boilers.

Earby.—Dynamo, battery, wiring, etc., at Sewage Disposal Works. Engineer, Council Offices. Aug. 16th.

Exeter. Repairs and renewals to battery, Devonshire County Asylum. Architects, E. H. Harbottle & Sons, County Chambers. (See an advertisement on another page.)

Hastings.—A main estimated to cost £80 is to be laid.

Leyton.—A Local Government Board inquiry was held last week concerning a loan of £18,158 for electrical extensions. The Inspector gave the usual intimation that a loan could not be authorised except to deal with firms working on Government contracts. There are a number of such consumers, but the Council expressed its anxiety to obtain sanction to the full loan in order to be quite ready to instal new plant immediately the war is over.

Lytham.—Application is to be made for the necessary loan for carrying out the scheme of obtaining a bulk supply for St. Anne's. The draft agreement has been drawn up.

Nelson.—Electric motors are to be installed at the sewage works.

St. Helens.—An expenditure of £15,000 is contemplated upon electricity extensions.

South Africa.—The Johannesburg Council requires two 3,000 kw. turbo-alternators. Town Clerk. Sept. 25th. Specifications may be seen at 73 Basinghall Street, E.C.

Wednesbury.—Additional plant for the King's Hill sub-station is required at a cost of £1,580; the necessary connecting cables are estimated to cost £420. Loans of these amounts in addition to £815 for further cable extensions are to be applied for.

Wiring

Bristol.—Wiring of sheds at docks. Engineer, Cumberland Place. Aug. 20th.

Hull.—Two houses, City Asylum. City Architect, Aug. 17th.

London: L.C.C.—Winchester Street Elementary School, Pentonville Road, N.; 93 lighting points. Chief Engineer. Aug. 23rd. (See an advertisement on another page.)

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Blackburn.—Additions to infirmary.

Edinburgh.—Additions to Inland Revenue Offices. H.M. Office of Works, London.

London.—New headquarters, Euston Road, Ancient Order of Foresters.

Manchester.—Warehouse, Turner Street. Architect, C. Swain.—Workshop, Buckley Street. Architect, Adshead & Topham.—Workshop, Openshaw. Architect, J. H. Lang.

Miscellaneous

H.M. Office of Works.—Enamelled conduit and fittings. Aug. 20th. (See an advertisement on another page.)

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Eastbourne.—The tender of the Stanton Ironworks Co. has been accepted of circulating water piping and valves.

Hull.—A tender of Messrs. Dick, Kerr & Co. for a turbo-alternator at £13,315 has been accepted.

APPOINTMENTS AND PERSONAL NOTES

In a note under this heading on p. 334 of our issue last week we referred wrongly to Mr. R. N. Mayne as the Borough Electrical Engineer at Nuneaton. Mr. Mayne, of course, is at Redditch.

The Sutton Coldfield Corporation requires an Electrical Engineer. Commencing salary £250 per annum. Applications to Town Clerk, Sept. 1st.

Messrs. John Walsh, Ltd., of Sheffield, require a man to buy for and manage their electric wiring and fittings department.

Three shift engineers are required in the Birmingham Corporation Electricity Department. (See an advertisement on another page.)

The North Metropolitan Electric Power Supply Co. want junior assistant engineers for switchboard work. (See an advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £83 to £84 (last week, £86 10s. to £87 10s.).

Agencies.—A Montreal engineer wishes to represent British makers of power plant apparatus and equipment. Board of Trade, 73 Basinghall Street, E.C.

A Melbourne firm desires the agency of a British firm manufacturing direct-current and three-phase motors, lamps, and electrical goods generally. Agent-General for Victoria, Melbourne Place, Strand, W.C.

Advance in Prices.—The General Electric Co., Ltd., announce an advance of 25 per cent. in their list prices of switchgear and switchboards.

LOCAL NOTES

Barking: L.G.B. and Extensions.—An application was made recently for a loan of £18,000 for new plant to meet the increasing demands upon the electricity undertaking. The Local Government Board has suggested that the amount in question should be reduced as much as possible and a revised estimate has been sent to the Board. Tenders have been provisionally accepted, and there is a disposition not to reduce the amount of new plant unduly having regard to many consumers being engaged on war work.

Belfast: Position of City Electrical Engineer.—Once more a small section of members of the Corporation have tried and failed to secure the resignation of Mr. T. W. Bloxam, the City Electrical Engineer. For quite a long time there have been attempts to secure a reorganisation of the electricity department, but neither the Electricity Committee nor the Corporation seem to have the courage to boldly tackle the job. Each has put the task upon the other in turn, and it is impossible for the outsider to understand what is behind all this manoeuvring.

Chester: Electricity Profits.—There was a net profit of £3,194 upon the working of the electricity undertaking last year. Some members of the Council are inclined to cavil at the result, as it is the least satisfactory yet shown by the

department, and the complaint was made, when the accounts were before the Council, that instead of the Dee Hydro Works enabling larger profits to be made, the reverse would seem to be the case. The general consensus of opinion, however, is that, considering the war, the result of the year's working is quite satisfactory.

Dublin: *Conserving Capital Resources.*—The Electricity Committee, in their quarterly report, calls attention to the fact that there is only the sum of £9,500 available for house services, meters, etc., and it is anticipated that this will carry the undertaking on until the end of the year if care is exercised. Until a new loan can be obtained no new customers will be connected up except under very exceptional circumstances.

Gillingham: *Diminishing Capital Powers.*—The Electricity Committee has only £200 remaining with which to deal with mains and services. Owing to the difficulty of getting new loans, this sum is to be reserved for services.

Greenock: *Large Profits.*—The electricity undertaking shows a profit of £10,000 on last year's working, the largest in the history of the undertaking.

Kingston-on-Thames: *Electricity Deficit.*—There was a loss of £1,295 on the electricity undertaking last year.

Manchester: *Proposed Investigation Committee.*—The City Council did not deal last week with the notice of motion to which reference was made last week, time being too short, and the matter will come up for consideration at the next meeting a month hence.

Norwich: *Electricity Profits.*—Notwithstanding the war, there was a net profit of £8,013 upon the working of the electricity undertaking last year, although for the first time in its history there was a slight decrease in the total output. From the available balance the sum of £4,055 is taken to complete the scheme of work of a permanent character undertaken three years ago, and the remainder is carried forward. In spite of an increase in the cost of coal from 16s. 11d. to 17s. 4d. a ton, there was an actual saving of £706 for the year due to higher efficiency in the plant.

Waterford: *Electricity Scheme to be Postponed.*—As might have been expected the Local Government Board has intimated to the Corporation that their electric lighting scheme, all the details of which have been prepared and which was estimated to cost £30,000, must, in present circumstances, be postponed.

The cost of obtaining the Order amounted to £200, in addition to which the expenditure incurred upon engineering assistance amounted to £872.

West Ham: *Electricity Accounts.*—The output for the year to March 31st, 1915, was 35,641,945, compared with 34,404,791 in the previous twelve months. There was an increase of 2½ million units in the supply for power and heating, but a reduction of approximately one-fifth of a million units in the consumption for lighting and tramways. Nevertheless, the total increase of 3·6 per cent. must be regarded as satisfactory in the circumstances. The result for the year, however, shows a deficit of £8,852, compared with a profit of £751 in the previous twelve months. This is more than accounted for by expenses amounting to over £10,000 arising directly out of the war, whilst in addition there has been charged to revenue account the sum of £3,123 in connection with the reorganisation of main and side street lighting, new meters, electric vehicles, and obsolete switch-gear written off. The extra cost of coal alone amounted to £2,538. Attention is called to the fact that the motor hire business undergoes but little change, and it is pointed out that although the hiring facilities are still much appreciated by power users, it is found easier every year to sell motors outright, as confidence in the use of electric power is now so generally established. On June 30th last 22 per cent. of the staff had joined the Forces.

Wimbledon: *Electricity Accounts.*—There was a net profit of £2,184 on the electricity undertaking last year. Of this, however, £2,115 are absorbed in special charges.

Wolverhampton: *Satisfactory Electricity Accounts.*—The electricity accounts last year show a net profit of £7,444. The sum of £2,215 is to be transferred to relief of rates and the balance placed to reserve. The cooking apparatus installed is equivalent to 980 h.p. There was a materially increased output, although the net profit is about £1,000 less than in the previous years.

York: *Overhead Wires.*—The Old Earswick Council having refused sanction to the erection of overhead wires in their district, Mr. J. W. Haine, the Corporation Electrical Engineer, has intimated that it will be impossible to give a supply there owing to the prohibitive cost of underground mains.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

London Supply Companies' Dividends.—The following interim dividends have been announced : Westminster Electric Supply Corporation, 6 per cent. per annum; County of London Co., 5 per cent. per annum (2½ per cent. last year); Charing Cross Co. (West End undertaking), 4 per cent. (5 per cent. last year); Kensington & Knightsbridge Co., 3 per cent. (8 per cent. last year). Metropolitan Electric Supply Co., 1 per cent. (4 per cent. last year). City of London Electric Lighting Co., 6 per cent. (5 per cent. last year).

Yorkshire Electric Power Co.—Although there was an increase in net revenue for the half year to June 30th, the net profit, owing mainly to the war, was slightly less than for the corresponding period of last year, being £9,873 against £10,414. The directors have not declared an interim dividend on the ordinary shares.

Bombay Electric Supply & Tramways Co.—At the annual meeting last week the chairman had a satisfactory position to report for 1914, in spite of the inevitable adverse effects of the war. There was a net increase in revenue of 8·25 per cent. The electric supply branch has expanded in particular, notwithstanding the loss of certain mills to the hydro-electric power company, which, however, is restricted to supplying factories and railways where the consumption is of 500,000 units per annum and upwards. A recent issue of ordinary shares has been subscribed for by the shareholders at a premium of 26 per cent.

Victoria Falls and Transvaal Power Co.—There was a carry forward for 1914, after meeting the preference dividend to April 30th, 1914, of £106,447. At the Brakpan Power Station 33,500 h.p. of plant has been added during the year. There is now an ample reserve of compressed air and electrical plant.

FOR SALE AND WANTED.

CJENNINGS & CO. can supply woodwork of any description at short notice, Stairs, Balusters, Newels, Hand-rails, Sash bars, Mouldings, Joinery. Support BRITISH industry, and refuse Foreign doors. We compete. Electric casings and underground troughing also supplied. Send 1s. 6d. (export 3d. extra) for the most up-to-date illustrated list (286 pages) of woodwork and timber in the World, to include 4-fold, brass-jointed boxwood rule. Will return money in exchange if not worth 2s. 6d. to you. JENNINGS & CO., 955 Pennywell Road, Bristol.

ELECTRICAL ENGINEERING BOOKS AT HALF PRICES!! Books on Electrical Engineering, Technical, and all other subjects supplied. Sent on approval. State wants. Catalogues Post Free. Books bought. W. & G. FOYLE, 121-123 Charing Cross Road, London, W.C.

PLATINUM UTENSILS, SCRAP, LAMP TOPS.—Best prices given by DERBY AND CO., LTD., 44 Clerkenwell Road, London, E.C. N.B.—Platinum sold.

PLATINUM, OLD ELECTRIC LAMP TOPS, Scrap Platinum purchased for cash. Best price given.—S. W. PRICE & CO., Platinum Refiners, 13 Great Queen Street, Kingsway, London, W.C.

WANTED, OLD METALS, Electric Lamp Tops, Scrap Platinum, Mercury Copper Cable, Scrap Iron. METAL CO., 2 Wakefield Road, South Tottenham.

SUMMARY

A DESCRIPTION, with photographs, of a temporary 10,000 kw. electricity works at Birmingham appears on p. 346.

QUEEN ALEXANDRA has presented to the Institution of Electrical Engineers a pair of telephones given to Her Majesty in 1878 and used for several years in Marlborough House. We publish a photograph of these, and also give an account of some of the other apparatus collected for the Institution museum (p. 347).

A STRIKING instance where the substitution of 30,000 kw. turbo-generators for 7,000 kw. slow-speed alternators has been possible with increase of engine-room floor space is presented by one of the stations of the New York Interborough Rapid Transit Co., which is being remodelled (p. 348).

THE automatic telephone exchange at Newport has commenced working (p. 349).

A PORTION of the suburban lines of the L. & S.W. Ry. will soon be running under electric traction (p. 349).

THE running of auto-converters in parallel is referred to in our Questions and Answers columns (p. 349).

AMONG the subjects of specifications published by the Patent Office last Thursday are protective systems, metal filament lamps, wireless telegraphy, insulating material, telephone relays, and cables (p. 350).

AN Inventions Branch of the Ministry of Munitions has been formed. The panel of technical advisers contains several well-known electrical engineers. (p. 350).

THE Board of Trade award in connection with the demand by London wiremen for an increase in wages has been issued. The award is for a temporary increase to 11½d. an hour—not 1s. as forecasted in our last issue (p. 351).

A LOAN of £8,760 is contemplated at Ipswich; Barnsley has been authorised to borrow £15,220, and Darlington £26,100; a crane is required at Keighley, static transformers at Rochdale, and electrical goods by the West Ham Union and the Powell Duffryn Steam Coal Co. (p. 351).

THE Glasgow Electricity Committee are contemplating experiments in the gas firing of boilers.—New consumers are being refused at Dundee owing to lack of staff to lay mains.—The Surbiton electricity undertaking is to be transferred to Callender's Cable & Construction Co. (p. 352).

A 10 PER CENT. interim dividend is declared by W. T. Henley's Telegraph Works Co. (p. 352).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING AUGUST 28TH, 1915.
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday, Wednesday, and Friday :—Drills 6.30 and 7.30.

Applications for Enrolment :—All applications for enrolment should be sent to the Commandant, Marconi House, Strand, from whom all particulars can be obtained.

E. G. FLEMING.

(Company Commander and Acting Adjutant.)

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

We are informed that good work is being done by the various sections of the Corps, both in drill and the special technical work under the staff of the London Electrical Engineers (T.F.) for which this Corps has been organised. Arrangements for the use of a miniature rifle range with rifles and instructor are being completed, so that members will be able to take rifle practice at any hour of the day most convenient to themselves. Recruits will be welcome from all those who are willing to fit themselves by training for military engineering work; it is not necessary that they should be members of one of the Engineering Institutions, although the Corps has been organised primarily among the membership of the Institutions, and application from men with an engineering bent, even if in other occupations, will be entertained. Applications should be addressed to Lt.-Col. C. B. Clay, Marconi House, Strand.

A TEMPORARY 10,000 KW. ELECTRICITY WORKS

THE regular and rapid increase of load at Birmingham up to the middle of last year made it necessary to add an additional 5,000 kw. of plant at the Chester Street Power House, which, in conjunction with the one at Summer Lane, generates current for practically the whole of the supply at Birmingham. At the same time, plans and specifications were prepared for a large power house on a site at Nечеллс, which is a suburb about $2\frac{1}{2}$ miles from the centre of the City. This power house is to have an initial capacity of 15,000 kw. and an ultimate capacity of 100,000 kw. The plant capacity of the Birmingham Corporation Electric Supply Department will therefore ultimately total 146,500 kw. (Summer Lane, 36,500 kw.; Chester Street, 6,960 kw.; Water Street, 3,040 kw., and Nечеллс, 100,000 kw.).

Contracts for the foundations of the Nечеллс Station had already been let and piling for the foundations commenced,

Mr. Chattock kindly placed at our disposal. Fig. 1, taken on May 11th, and Fig. 2, on July 12th, show the very rapid progress made. In the latter view the relative positions of the building are seen. On the left is the switch-room, which has a building to itself, and is separated from the engine and boiler houses by an inclined way leading up to the Corporation Destructor Works, which occupies an adjoining site. The engine and boiler house are built against one another, the boiler house being the larger building on the right in Fig. 2. Between this building and the five cooling towers (four of which are seen in the illustration) there is a roadway 30 ft. wide. The dimensions of the buildings are approximately as follows: boiler house, 90 ft. by 65 ft.; engine house, 90 ft. by 60 ft.; switch house, 60 ft. by 28 ft.; with a small battery room, 43 ft. by 18 ft. adjoining. A steel-frame structure has been provided, filled in with a special corrugated asbestos-cement material (made by Thompson Hughes-Jones & Co., Budge Row, London, E.C.). This material, which resembles whitened corrugated

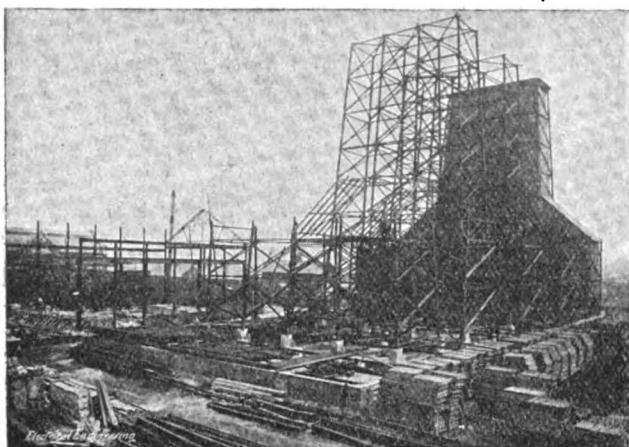

FIG. 1.—VIEW OF THE SITE ON MAY 11TH.

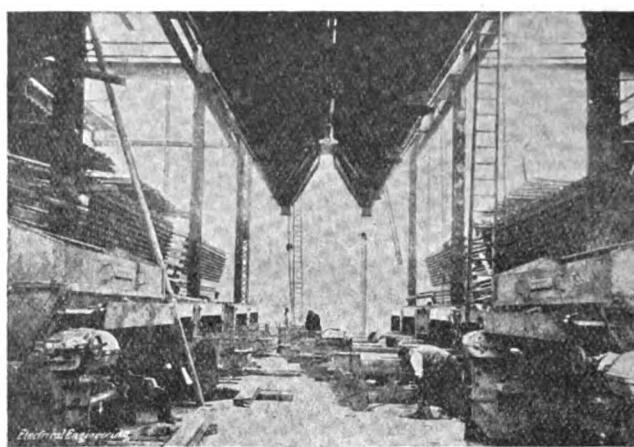

FIG. 3.—THE BOILER HOUSE, JULY 19TH.

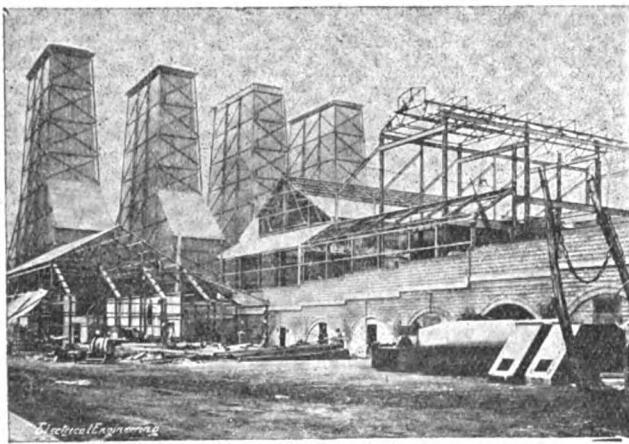

FIG. 2.—VIEW OF THE SITE ON JULY 12TH.

when it became evident that the abnormal growth of the load demanded would require new plant to be in operation far sooner than would follow in the ordinary course, and that it would be advisable to provide for the contingency of 10,000 kw. being needed in the coming winter.

As has been already recorded in our columns (*ELECTRICAL ENGINEERING*, Jan. 21st, 1915), Mr. R. A. Chattock, the City Electrical Engineer, solved the difficulty by deciding to erect a temporary station on ground adjoining the site acquired at Nечеллс, to get this into operation as soon as possible, and to utilise, so far as could conveniently be done, plant which would be ultimately destined for the permanent station. Work was commenced last January, and it is expected that the temporary station will be completed and in operation by October.

The site is "made" ground, and for the foundations a 12 in. raft of concrete, reinforced with expanded metal, has been employed, and the pressure upon this has been kept down to $\frac{1}{2}$ to 1 ton per sq. ft. The main stanchions have steel grillage foundations to reduce the weight.

We have selected a few views of the work during construction from an excellent collection of photographs which

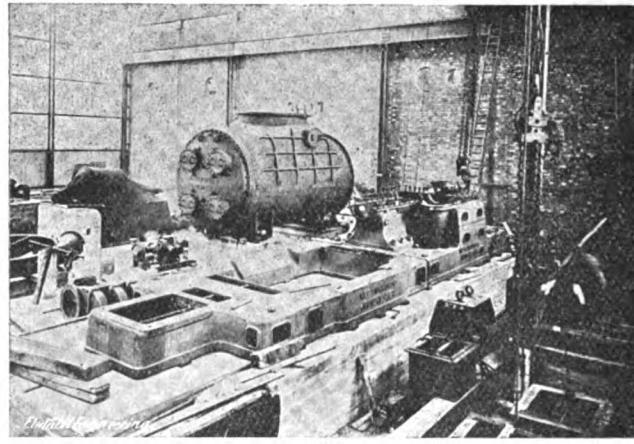

FIG. 4.—THE ENGINE HOUSE, JULY 19TH.

iron in external appearance, is employed for the partitions as well as the outside walls and part of the roofing; in the switch house glazing is only employed on the part not over the apparatus. The asbestos-cement is guaranteed for a life of at least twenty years.

Six Babcock & Wilcox marine-type boilers, each capable of evaporating 33,000 lb. of water per hour, are being put in. They will, of course, be used with economisers in the permanent station, but these are dispensed with at the temporary one. The Louis Prat induced draught system is employed. For the feed-water a large Clarke-Chapman direct-acting reciprocating pump, with a capacity of 25,000 gallons per hour, is being put in, and in addition two high-speed turbine-driven Worthington pumps. Above the boilers are twelve bunkers, each of ten tons capacity. A Herbert Morris telpher conveyor, which is being put in for the coal and ashes, spans the 40 ft. interval between the boiler house and the Birmingham and Warwick Junction Canal.

A large part of the steel work of the boiler house will be utilisable for the permanent building and also the telpher conveyor, but the engine house steel work will not come in to any very large extent for the larger engine house. The

magnitude and urgency of the temporary scheme can be gauged by the fact that the cost of the temporary foundations alone is estimated at £10,000.

In the engine-room two British Westinghouse 5,000 kw. turbine-driven sets are being installed, generating three-phase current at 5,500 volts, 25 cycles per sec. They will be supplied with super-heated steam at 200 lb. per sq. in., and the generators are to be air-cooled through two "wet" air filters, a Sturtevant and a Heenan & Froude. For each turbine there is a 200 h.p. turbine-driven air and circulating pump, arranged to exhaust either into a low pressure stage of the main turbine, or to ejector heaters in the hot well, or to the atmosphere.

A motor generator and rotary converter are being put in for the works supply and a small battery as stand-by, which also serves for working the trip-coils of the switch-gear.

Four of the five fine wooden Davenport cooling towers, over 100 ft. high, are seen in Fig. 2, and it is noteworthy that they were completed to the day of the contract period in spite of the difficulties of obtaining material and labour at the

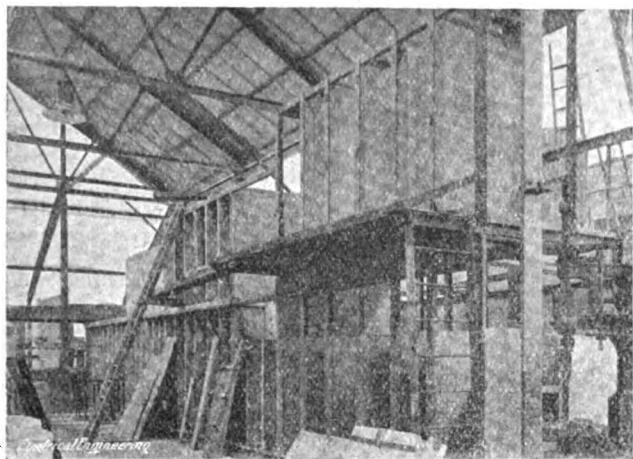

FIG. 5.—THE SWITCH HOUSE, JULY 25TH.

present time. Each can cool 185,000 gallons of water from 95° to 75° F. at 80 per cent. humidity of atmosphere.

The switch house will contain the control board as well as the high-tension switchgear itself, and is to be connected to the engine-room by a Chadburn telegraph. The gear is being supplied by the British Thomson-Houston Co. and follows their most modern lines. Moulded stone cubicles are employed, and, in accordance with present practice, large oil-cooled reactances are included in the generator leads. These reactances are placed at one end of the switch-room, and to prevent any risk of fire this portion, about 12 ft. in width, is walled off from the rest of the switch house with the similar asbestos-cement material as is being used for the rest of the building.

Two 0.25 sq. in. Callender split conductor feeders are being laid to the Saltley sub-station to start with, and four ring mains which run out to the district. Eventually the station will be run in parallel with the Summer Lane station, about two and a half miles distant at the other side of Birmingham.

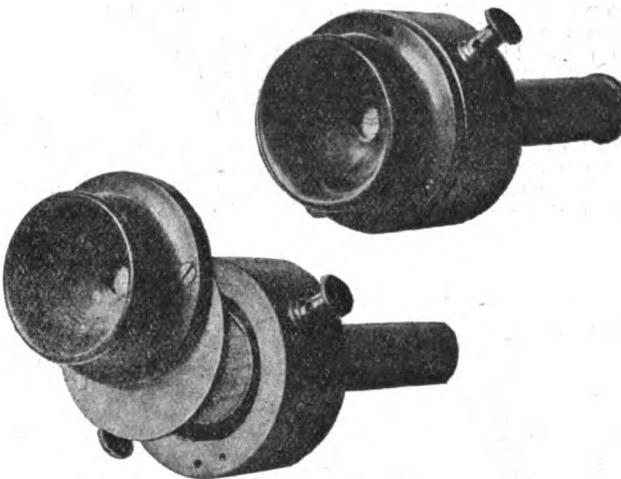

Our thanks are due to Mr. R. A. Chattock for permission to inspect the station, an inspection which was greatly facilitated by the courtesy of Mr. E. A. Mills, the Assistant Constructional Engineer, who is also responsible for the very excellent photograph of the interior of the switch house.

Fatal Shock from Trolley Standard.—An inquest was held last week into the death of a man named Hemingway, who worked as a car cleaner at Halifax. The deceased was found suffering from shock on the top of an open deck car with one hand on the trolley standard and the other on the rail, and died soon after. Mr. J. W. Galloway, tramways engineer, attributed the trolley standard being live to the fact that it had previously been damaged by lightning, which had pierced the insulation and fused the wire provided to earth the trolley standard. This wire was quite small, and the fusing of it was usually noticed and reported. It had not, however, been noticed on this occasion, and the car did not happen to have been examined before cleaning. Instructions have now been given to take the trolley off the wire before a car is cleaned. A verdict of accidental death was given.

THE INSTITUTION MUSEUM Queen Alexandra's First Telephones

THE Institution of Electrical Engineers is gradually collecting some interesting historical specimens of electrical apparatus, and the latest acquisition is a pair of telephone receivers presented to Queen Alexandra (then Princess of Wales) in 1878. Those who remember or have studied the history of the early days of telephony will remember that the invention of the telephone by Alexander Graham Bell in 1877 was followed by the manufacture of large numbers of telephones by amateurs, as the construction of the instrument was so easy and simple. Only one pair of instruments was used, as a rule, the same instrument being used for receiver and transmitter. The telephones which have been presented by Queen Alexandra to the Institution are of this class; they were made on H.M.S. *Thunderer*. We believe we are right in saying that they were taken into actual use between her Majesty's sitting-room and the schoolroom at Marlborough House for quite a number of years. The illustration below is from a photograph which we have had taken of the telephones, one being opened to show its construction. The cases are of boxwood, with terminals at the side. A pole magnet, very weak now and possibly not over strong then, passes inside the handle, and at the end is a fairly long coil of wire. Possibly the most interesting feature, in view of the fact that the instruments worked, is the very thick diaphragm, quite probably cut out of a thick ship's biscuit-tin.

In this connection, we may mention that the original telephone installed for Queen Victoria in 1878, between Osborne

House and Cowes, and worked therefore over about a mile of wire, is also in existence, and it is not improbable that Messrs. Julius Sax & Co., the present owners, will present it to the Institution.

The Institution has some other early specimens of telephone instruments, presented by the National Telephone Co., Ltd., among which is one of the so-called "electro-motograph" chemical receivers, used in conjunction with the carbon transmitter (invented simultaneously by Edison in America and Hughes in England), before the combination of the Bell-Edison Companies, when the Edison Company were unable to use the Bell telephone patent. The user of the instrument has to turn a handle which causes a chemically-treated chalk cylinder to revolve. A platinum-tipped tongue bears against the cylinder, and is fixed to a mica diaphragm. The friction on the cylinder varies with the current received, and causes the diaphragm to vibrate and to emit the sound of the voice—distorted in much the same way as in a gramophone. There is also a delightfully antique and very primitive exchange switchboard, but this is still in the basement of the Institution, and although its history must be interesting it is so far unrecorded.

Probably the most interesting piece of apparatus in the Institution collection is a Holmes magneto-electric machine, which was one of two installed in 1870 at Sowter Point lighthouse, and has actually been working the projectors there regularly until two years ago. It was received at the Institution last month, and, on account of its weight (between two and three tons) has had to be left in the basement.

The Institution has also been presented with two other historical machines, viz., the Gramme dynamo used for the first experimental street arc lighting on the Thames Embankment, and a Gramme machine which was in constant use for lighting the *Daily Telegraph* offices from 1882 to 1908.

Specimens of cable from the first English Channel and Atlantic cables down to the very latest loaded telephone sub-

marine cable, form an interesting collection, as do also the early incandescent lamps, switches, and fuses, presented by various members. One of the first syphon recorders has been given by the Eastern Telegraph Co. The collection of electricity meters, starting with zinc-zinc-sulphate electrolytic meter, in which the plates had to be weighed to ascertain the current consumption, is probably unique, although it has several gaps. There is also a Jablockhoff candle, but, to complete the apparatus used for the original Thames Embankment lighting, one of the holders used for these arc lamps would be valuable; if any of our readers has one in his possession, we are sure that the Institution would be most glad to receive it.

Mention must also be made of the telephone instruments used on the Scott Antarctic expedition, which were given back to Mr. Frank Gill when the survivors returned. A description of these instruments before they were sent out appeared in ELECTRICAL ENGINEERING, Vol. VI., page 427 (June 30th, 1910).

It will be seen that considerable progress has been made in collecting historical apparatus for the Institution museum, and it is to be hoped that opportunity will be found after the war is over and the Institution can take into use the rooms at present lent to the Government, that it will be classified and displayed in a suitable manner. A catalogue should also be posted there of the collection already existing at South Kensington, or, better still, if space will permit, this should also be housed at the Institution after the war, so that the whole may be under one roof.

30,000 KW. TURBO-ALTERNATOR

AN interesting example of the replacement of bulky reciprocating plant by turbo-generators giving many times the output in the same floor space is presented by the remodelling of the generating plant in progress at the 74th Street station of the New York Interborough Rapid Transit Co. The station, as originally equipped in 1901, contained eight Allis Chalmers horizontal-vertical cross compound engines, each driving a Westinghouse 7,000 kw. flywheel alternator running at 75 r.p.m., and a 7,500 kw. Westinghouse turbo-alternator was subsequently added. When the remodelling is complete the reciprocating plant will be replaced by eight 30,000 kw. turbo-generator units, raising the capacity of the station nearly 400 per cent. The comparative sizes of the old and new sets are shown in Figs. 1 and 2. According to the *Electrical World* two of the new 30,000 kw. turbo-generator units were in operation

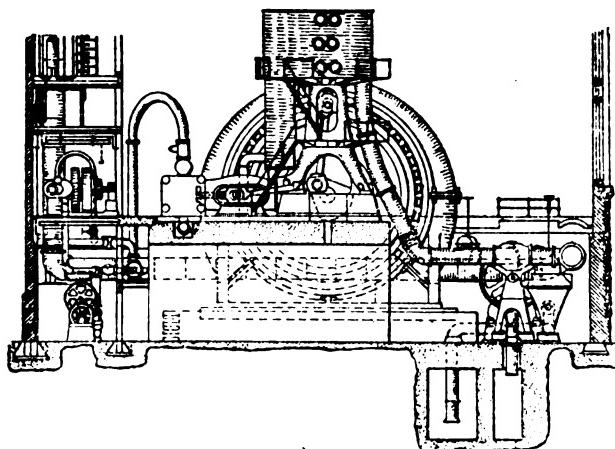

FIG. 1.—CROSS-SECTION OF ENGINE ROOM SHOWING OLD 7,000 KW. RECIPROCATING SETS.

last April, carrying all of the load except during the peaks, when the remaining 7,500 kw. turbine and four reciprocating engines are sometimes called upon for assistance. One unit is quite complete, and the second, while assisting in carrying the load, is undergoing an exhaustive series of tests. The foundations for the third unit are under construction. The portion of the alterations now in hand as a first instalment involve principally the substitution of three turbine generators for four engine generators; the making over of one-half of the boiler plant opposite the turbines by replacing Roney stokers with Taylor underfeed stokers, adding superheaters and removing the economisers; the partial replacement of motor-driven triplex with turbine-driven centrifugal boiler-feed pumps, and the complete rearrangement of the electrical switching system with the addition of current-limiting reactors.

Each 30,000 h.p. turbine set consists of a cross compound

arrangement of two turbines, comprising a 1,500 r.p.m. single-flow reaction turbine and a 750 r.p.m. double-flow reaction turbine, connected as a compound machine with a large receiver between the two. This arrangement was chosen to simplify design problems, particularly as regards temperature range, blade speeds, and steam congestion. The efficiency guaranteed is such that 75-75 per cent. of the heat energy available between admission and exhaust conditions will be delivered in electrical form. The turbines rest upon a foundation consisting of a steel frame incased in concrete, leaving most of the space below available for condensers, receiver, and pumps.

The Worthington surface condenser, of 50,000 sq. ft. cooling surface for each unit, is of the twin-shell type, of simple construction, and practically self-contained. The condensers are hung directly from the turbine bedplates, but their weight is supported on spring jacks. Circulating water for each pair of condensers is supplied by a pair of three-motor centrifugal pumps driven by steam turbines rated at 240 h.p. each. The condensate pumps for each unit are of the centrifugal type, turbine-driven and of 800 gallon per minute capacity each. One pump is sufficient, the second being a reserve. One reciprocating dry-vacuum pump is provided for each unit, with a capacity for two. The vacuum pumps are cross-connected between units.

In the boiler house the original boilers are being retained, but one-half are being rebuilt to the extent of adding standard B. & W. superheaters to give 200 deg. of superheat when

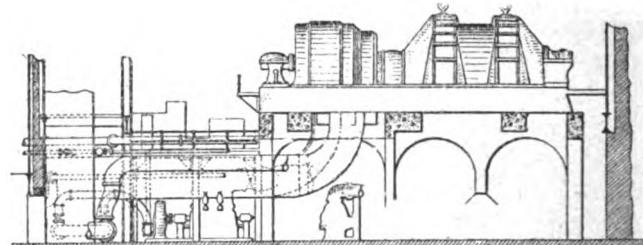

FIG. 2.—CROSS-SECTION OF ENGINE ROOM SHOWING NEW 30,000 K.W. TURBO-GENERATOR.

the boilers are delivering three times their rated output. The Taylor underfeed stokers which are being installed under one-half of the boilers are standard, but on four of the boilers air tuyères have been installed along the side walls, directing jets over the fires and protecting the side walls. As the remodelled boiler plant provides only superheated steam, provision had to be made for the auxiliary supply of saturated steam for the reciprocating engines. In the line connecting the old and new boiler plants is connected a receiver from one of the old engines. In the boiler-room basement much space has been saved by the removal of four triplex pumps, accommodating three turbine-driven centrifugal pumps sufficient in capacity for the entire plant and the stoker fans and turbines. For each pair of boilers there is one turbine driving two stoker fans direct and the stokers also through helical reduction gears from the blower shafts. In the basement ash pits of expanded metal plastered with cement have been recently put in.

The electrical distribution of the plant has been entirely remodelled with a view to providing adequately large switches, feeders, etc., and to protecting the underground cables from damage due to the large amounts of energy which will now be concentrated on short-circuit. There are two sets of buses, main and auxiliary, to which each old and new generating unit is connected. Between the generator and the main bus is a reactor with 5 per cent. reactance, and between it and the auxiliary bus is one with 2 per cent. reactance. The main bus is sectionalised through oil switches, groups of feeders being taken off from each section.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

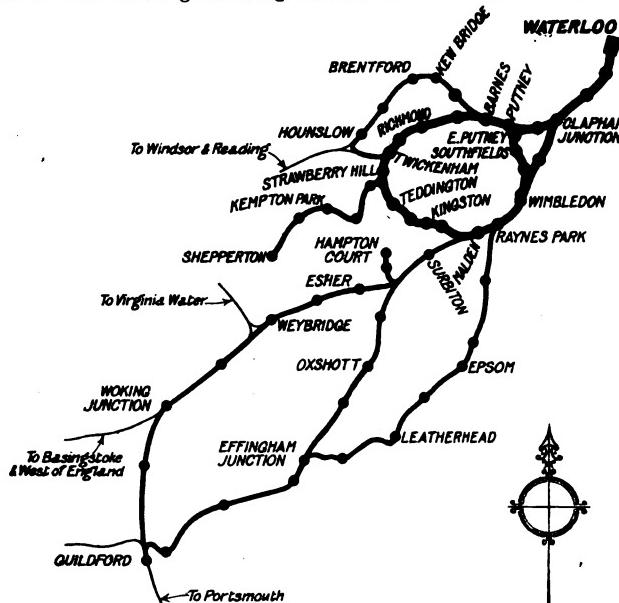

The new 2,000 line automatic telephone exchange at Newport (Mon.), which is so far the largest completed automatic exchange in the country, commenced working on Saturday. About 1,500 of the new instruments have been connected up. The exchange has been equipped by the Automatic Telephone Manufacturing Co., Ltd., on the Strowger system (see ELECTRICAL ENGINEERING, May 23rd,

1912, p. 278), which is already in operation at Epsom and at the Central Telegraph Office, London, and is being installed at Accrington, Portsmouth, and Chepstow. The other two automatic exchanges working are at Hereford (Lorimer system) and Darlington (Western Electric system). The Western Electric Co. have also exchange equipment in hand for Dudley, and automatic equipments on yet another system for Grimsby and Stockport are on order from Siemens Bros. and Co., Ltd.

According to a Reuter telegram from Tokio, wireless communication has been established between the new station at Funabashi, near Yokohama, and Honolulu, a distance of about 4,000 miles.

ELECTRIC TRACTION NOTES

The conversion of the suburban lines of the London & South Western Railway to electric traction is now in an advanced stage, and electric trains are to be put into regular service on the portion known as the Kingston loop (shown by thick lines in the map) in a few days' time, while the electrical working of the Hounslow, Shepperton, and Hampton Court and other sections will follow soon after, until the 140 miles of single track already equipped are in use. A frequent service of three- and six-coach trains will be run. Each permanently coupled three-coach unit will have a two-motor bogie at both ends and will take current at 600 volts from third and fourth rails. The main generating station at Durnsford Road, near

Wimbledon, is nearly complete and a portion of the plant is ready for running. It will have a capacity of 25,000 kw. and will be supplied with condensing water from the River Wandle. It will supply power at 11,000 volts to sub-stations containing rotary converters at Waterloo, Clapham Junction, Raynes Park, Kingston, Twickenham, Barnes, Isleworth, Sunbury, and Hampton Court. The sub-station buildings are all complete and the plant is in process of installation. The track conductor rails are of 100 lbs. per yard weight of a special high conductivity steel. The running rails are bonded and cross-bonded. Some further particulars of the scheme were given in ELECTRICAL ENGINEERING, December 13th, 1912.

The Hove Corporation has decided to dismantle the overhead equipment which was put up for the experimental trolley bus service in connection with a joint service for Brighton and Hove. Ever since Parliament sanctioned the scheme some years ago, the two Corporations have been unable to agree, and the Board of Trade had been asked to arbitrate. Now, however, a mutual agreement to abandon any further work until after the war has been come to.

The London & North Western Railway Co. has found no difficulty in raising £1,500,000 ten-year redeemable preference stock at 96, for the completion of the Euston-Watford Electric Railway.

The Chester Corporation is to purchase three 2-ton electric battery wagons at £3,200. The cost is to be spread over four years. A saving of £124 per annum is anticipated over the present system of refuse removal.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,456.

I wish to start up a 3-phase S.C. induction motor direct from an existing alternator without switchgear between the machines. Under these conditions, how will the torque of the motor vary with the speed? Is it necessary to separately excite the alternator field during the starting period? Are there any disadvantages in the method of starting?—M. M."

(Replies must be received not later than first post, Thursday, August 26th.)

ANSWERS TO No. 1,454.

Two 95-kw. auto-converters are being driven from a 500-volt system, and are supplying current at 300 volts to a motor load. When the machines are paralleled an equalising switch is closed. Until recently, the machines when started up built up to a pressure of 330 volts each and no trouble was experienced in paralleling them; but recently for some unknown reason one machine builds up to 350 volts. The result of this is, the equalising switch is burnt out after the machines have been operated a few times. What is the cause of this rise in pressure on one machine, and what is the best way to locate the fault and remedy it?—ESTIMATOR."

An award of 10s. is given to "Arch" for the following reply:

An auto-converter is in reality a motor and a generator coupled together electrically as well as mechanically; in fact, the motor and generator armatures are connected in series across the supply mains, whilst the load is across the generator armature only. There are several forms of auto-converters on the market, some with a single armature winding and split poles, some with a single core but two armature windings, others with two armatures, &c. Since "Estimator" does not state the arrangement of the machines referred to in the question, it is only possible to make some general remarks concerning his trouble.

The increase of voltage experienced on one of the machines must be due either to an increase in the speed or to an increase of the flux in the poles on the generator side of the set. If the poles have been tampered with, the above could respectively be accounted for by an increase in the length of the airgap under the motor poles, or a decrease in that under the generator poles. Other possible causes, such as a short-circuit of some of the armature turns on the motor side, or a change in the resistance of one or more of the field coils, could most easily be detected by comparing the resistances of the different circuits of the one converter with those of the other.

If no fault can be found with the windings, the simplest method (and the one generally employed on test-plates) of reducing the voltage to its correct value is to increase the length of the air-gap under the poles on the generator side, or decrease—if clearance permits—that under the poles on the motor side of the set. These alterations are accomplished by removing or inserting thin iron sheets at the back of the poles.

No other award is made.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 12th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

23,449/13. Protective System. E. G. WATERS. A protective system in which the cutting out of the faulty sections is effected by fault currents in two separate protective conductors for each cable section. These conductors are connected with tripping means at the ends of the cable sections. (One figure.)

29,981/13. Metal Filament Lamps. H. A. GILL (*Wolfram Lampen A.G.*). Incandescent lamps wherein a single conductor coiled into a close helix is looped to and fro over a number of supports like a plain wire filament in order to accommodate a great length of wire. The convolutions are arranged so that the axis of the helix is in a plane at right angles to the longitudinal axis of the lamp. (Three figures.)

11,102/14. Wireless Telegraphy. E. VON LEPEL. A method of producing high-frequency oscillations from a direct-current source by partially discharging a condenser by means of an auxiliary condenser of the same order of capacity, the charge of which is periodically reversed. The charging circuit is timed relatively to the frequency of the spark discharge, so that the voltage across the spark gap at the moment of discharge is approximately twice that of the D.C. source. (16 figures.)

11,112/14. Insulation. MEIROWSKY & Co. and J. M. MEIROWSKY. Manufacture of fibrous insulating material by compressing or rolling separate sheets previously impregnated with oil and provided with a layer of resin.

17,332/14. Incandescent Lamps. W. O. HUGHES. A lamp filament of annealed and wire-drawn uranium in a pure state produced by treatment of uranium tetrachloride with metallic sodium and potassium chloride.

275/15. Telephone Relay. WESTERN ELECTRIC Co. (*W.E. Co., U.S.A.*). A telephone relay system comprising an arrangement of a wave amplifier of the thermo-ionic or "audion" type with two separate cathode streams in one bulb connected so that one reacts to each half wave. (Five figures.)

4,761/15. Cables. BRITISH INSULATED & HELSBY CABLES, LTD., and J. BROTHERTON. Heavily sheathed rubber cables are provided with grooves or indentations in the covering at the point which comes inside the gland on entering a junction box so that the packing grips the cable and makes a watertight joint. (Eight figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Arc Lamps: GREINACHER [Arc-incandescent lamp] 18,149/14.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: GROSSMANN [Insulating compound] 20,409/14; FOSTER [Attaching unarmoured cables] 3,213/14.

DYNAMOS, MOTORS, and TRANSFORMERS: SIEMENS BROS. DYN. WKS. [*Siemens-Schuckertwerke Ges.*] [Control of electric machinery] 3,658/14; PHENIX DYNAMO MNF. CO. and POHL [A.C. motors] 4,803/14; KENNARD [Electric motors] 7,342/14; B.T.-H. CO. (*G.E. Co., U.S.A.*) [Squirrel-cage windings] 21,676/14; IMRAY (*Siemens-Schuckertwerke*) [Transformers] 22,243/14; NOLAN [Cooling dynamos and motors] 24,496/14.

Heating and Cooking: WHEELOCK [Water-heater] 22,150/14.

Ignition: LAW and TOVARISCHESTVO M. HELFFERICH SADET [Ignition devices] 17,849/14.

Incandescent Lamps: GLADITZ [Incandescent lamps] 3,209/14; BARON VON BÁTORKÉZ UND VERINKHÁZ [Machine for repairing incandescent lamps] 11,621/14.

Storage Batteries: VAN RADEN & CO. and METZ [Accumulators] 2,548/14.

Switchgear, Fuses and Fittings: IGRANIC ELECTRIC CO. (*Cutter Hammer Mnf. Co.*) [Motor controllers] 20,322/14.

Telephony and Telegraphy: SIEMENS & HALSKE A.G., LAIDLAW and PETTIGREW [Telephone system] 1,157/14; SIEMENS & HALSKE A.G. [Telephone register circuits] 11,211/14; SCHIESSLER [Antennae] 11,709/14; MELLERSH-JACKSON (*Fratelli Marzi di G.B.*) [Production of sustained oscillations] 12,259/14; ORLING and ORLING'S TEL. INSTR. SYND. [Telephone circuits] 17,920/14; B.T.-H. CO. (*G.E. Co., U.S.A.*) [Coherers] 18,751/14; BLOXAM (*Teletypograph Ges.*) [Writing telegraphs] 20,137/14; IMRAY (*Siemens & Halske A.G.*) [Telephone register circuits] 1,006/15,

and [Selecting devices] 1,995/15; WESTERN ELECTRIC CO. (*W.E. Co., U.S.A.*) [Wave amplifier] 2,093/15; ELEKTRO-TECHNISCHE SPEZIALCONSTRUKTIONEN GES. [Thermic telephones] 4,353/15; TUBRI [Telephone instruments] 7,963/15.

Traction: VON KANDO [Overhead conductors] 1,452/14, and [Electrically driven vehicles] 4,233/14; VICKERS, LTD. (*Krizik*) [Train lighting] 4,681/14; HOBBHOUSE, SLINGO, GUNTON, POWELL and KINGSTON [Electric Railway Systems] 15,539/14; CROSSLEY [Electric carriage door locks] 17,511/14; DRINKELL and EVANS [Automatic signalling] 19,879/14; BILES [Petrol-electric traction] 6,805/15.

Miscellaneous: LUBACH [Indicator] 1,181/14; REICH [Fire-alarms] 4,188/14; STERLING TELEPHONE & ELECTRIC CO. (*Telephon-fabrik A.G. vorm J. Berliner*) [Signalling apparatus for mines] 4,223/14; VULCAN MASCHINENFABRIKS A.G. [Magnetic clutches] 17,455/14; BÜNTE & REMMLER [Vacuum cleaners] 17,628/14; KERR [Electric alarm connected with locks] 21,643/14; HOLZ [Electric concertina] 21,766/14; STILLE [Electro-optical cells] 1,973/15; F. KRUPP A.G. [Sparkless circuit interruption] 2,462/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

DYNAMOS, MOTORS, TRANSFORMERS, &c.: GIANDINOTO [Semi-static transformer] 10,518/15; EMIL HAEFELY & CO., A.G. [Vacuum drying and impregnating of coils] 10,803/15.

Heating: SAMSON APPARATE BAU-GES. [Thermostatic control] 10,734/15.

Ignition: DAIMLER MOTOREN GES. [Sparkling plugs] 10,204/15.

Instruments: LANDIS & GYR A.G. [Meters] 10,676/15.

Miscellaneous: DEUTSCHE SCHWEISSMASCHINEN BAU & VERTRIEBS GES. [Electric welding] 10,668/15.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: CROMPTON & CO., LTD., and C. F. TUBBS [Arc lamps] 9,693/06.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: W. E. LAKE (*P. Shröder*) [Cable armouring] 9,077/08.

DYNAMOS, MOTORS and TRANSFORMERS: T. VON ZWEIGBERGK [Motor control] 8,913/05; A. G. BROWN, BOVEY & CIE. [Constant current converter] 9,146/08.

Heating and Cooking: H. J. DOWSING [Folding electric light bath] 9,012/05.

Incandescent Lamps: E. A. CAROLAN (*G.E. Co., U.S.A.*) [Lamp exhausting] 9,590/03.

Switchgear, Fuses and Fittings: A.E.G. [Protective system] 21,603/08.

Telephony and Telegraphy: L. M. ERICSSON [Telephone ringing keys] 9,800/02 and [Telephone switchboards] 9,801/02; P. MULLIGAN [Telegraph instruments] 10,223/09.

Traction: COMPAGNIE DE L'INDUSTRIE ELECTRIQUE ET MÉCANIQUE [Railway motor control] 9,630/06.

Miscellaneous: E. C. and P. H. STEVENS and C. G. MAJOR [Lift control] 9,382/03; A. RICHARDSON [Electric sign with changing letters in relief] 9,008/08; M. A. NEWSTETTER [Automatically controlled independent lighting plant] 10,198/09.

A MUNITIONS INVENTIONS BRANCH

FOLLOWING more or less the example of the Admiralty, which recently constituted an Inventions Board, with Lord Fisher as Chairman (ELECTRICAL ENGINEERING, July 22nd, p. 310), the Minister of Munitions has created an inventions branch for his department. Mr. E. W. Moir, M.Inst.C.E., is comptroller, and the following have accepted an invitation to serve on a panel of honorary scientific and other experts:—

Colonel Goold Adams; Horace Darwin, F.R.S.; Macdougal Duckham; W. Duddell, F.R.S.; Sebastian Z. de Ferranti; Dr. R. T. Glazebrook, F.R.S.; Sir Robert Hadfield, F.R.S.; Professor J. S. Haldane, F.R.S.; Colonel N. B. Heffernan; Sir Alexander Kennedy, F.R.S.; F. W. Lanchester; Professor A. P. Laurie; Professor Vivian Lewes; Michael Longridge; W. H. Maw; Sir Hiram Maxim; Captain Moore, R.N.; Sir Henry Norman, M.P.; F. G. Ogilvie; Major-General G. K. Scott-Moncrieff; Wilfrid Stokes; James Swinburne, F.R.S.; Sir J. J. Thomson, F.R.S.; A. J. Walter, K.C.; C. J. Wilson.

This panel will assist the comptroller and his staff with the examination, investigation, and development of any projects that may be considered worthy of attention.

The address of the branch is Armament Buildings, Whitehall Place, London, S.W.

INCREASE IN LONDON WIREMEN'S WAGES

THE following is the text of the Board of Trade award issued last Friday in connection with the demand made by the electric wiremen in London for an increase in wages from 10½d. to 1s. per hour. It will be seen that 11½d. is awarded:

On the 9th March, 1915, application was made by the London District Secretary of the Electrical Trades Union to the London Electrical Masters' Association for an advance of wages from 10½d. to 1s. per hour, and a reduction of the working hours to 48 per week.

The Employers' Association intimated that they were unable to accede to this request, and these matters were therefore considered at a meeting of the Joint Committee of representatives of the parties on 30th April, and at a General Meeting of the Electrical Masters' Association on 10th May, but no agreement was arrived at on these questions.

On the 10th June application was made to the Chief Industrial Commissioner by the Secretary of the men's Union for the appointment of an arbitrator to decide upon the application for an advance of wages from 10½d. to 1s. per hour for electrical wiremen and fitters, with *pro rata* advances to electricians' labourers and assistants, it being subsequently explained that the question of the reduction of hours was unreservedly withdrawn.

After some negotiations the Employers' Association concurred in the reference of the matter to arbitration, and the Chief Industrial Commissioner having appointed me, David Harrel, to act as arbitrator in the matter, I heard representatives of the parties on 5th August.

After giving careful consideration to the statements and arguments made before me, I hereby award that the existing rate shall be raised from 10½d. to 11½d. per hour, with *pro rata* advances to electricians' labourers and assistants, such advanced rate to come into operation as from the beginning of the first pay day following the date hereof, and the advance now awarded to be regarded as war wages, and recognised as due to, and dependent on the existence of the abnormal conditions now prevailing in consequence of the war.

If any question arises as to the interpretation of this award it shall be referred to me.

(Signed) DAVID HARREL.

[We stated in our last issue that it was understood that the men had been given the increase from 10½d. to 1s. which they had sought. This turns out to have been incorrect. The Secretary of the Electrical Contractors' Association points out to us that he has been put to considerable inconvenience and annoyance by the very large number of firms who have communicated with him as a result of this announcement in our paper, and we can only express our sincere regret that this should have been the case through our having published information which has apparently emanated from an unreliable source.]

AN IMPROVED WEIGHING MACHINE

MESSRS. W. and T. Avery, Ltd. (Soho Foundry, Birmingham), have sent us some particulars of an improved weighing machine provided with an automatic ticket printing arrangement which should be very useful in preventing carelessness or fraud on the part of the weighman, and ensuring accuracy in weighing. The important feature is that the ticket printing mechanism is only unlocked when a balance has been obtained, and the cover closed and sealed so that no further alteration of the poises can be made. Another advantage of the machine, which is aptly named the "Stopfraud" is, that in cases where repetition weighments of say 1 cwt. sacks or packages are to be delivered and checked out, the poises can be set at 1 cwt., the machine locked by means of a padlock, and any untrained employee told off to check out any number of packages; it being quite impossible for overweight bags or lots to be sent out, since no ticket can be printed for weights that are even a fraction in excess of the specific variation which has been allowed in setting the machine. Again, when one package has been weighed, the ticket slot is absolutely closed against the insertion of a fresh ticket, and remains so until the package has been actually removed from the weighing platform. The firm has a scheme of maintenance contracts under which these machines can be supplied, and especially trained mechanics are available at the 150 branches and depots which Messrs. Avery have established throughout the British Isles.

Obituary.—Sec.-Lieut. W. A. B. Kirwan Ward is reported to have died from wounds received at the Dardanelles. Before the outbreak of war he had been since 1913 with the Relay Automatic Telephone Company (then called the Betulander Automatic Telephone Company), by whom he was employed in London and in France in connection with the installation erected in the Bois de Boulogne. His early experience was with the National Telephone Co. and for a short time he worked for the Constantinople Telephone Co.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Barnsley.—The L.G.B. has sanctioned a loan of £15,220 for plant extensions.

Basingstoke.—Mains are to be laid in various parts of the town where there are prospective consumers.

Darlington.—The L.G.B. has sanctioned a loan of £26,100 for extensions to deal with war requirements. The application was for £34,050, one of the items disallowed being £5,000 for mains.

Huddersfield.—The Meltham Council has approached the Corporation with regard to a supply of electricity.

Ipswich.—Some time ago the Corporation applied for a loan of £7,350 for sub-stations and equipment. The L.G.B. withheld consent until the actual cost could be ascertained more precisely. It is now found that the cost will be £8,760, and sanction to this amount is to be asked.

Keighley.—Overhead 40-ton travelling crane for Electricity Department. Borough Electrical Engineer. August 24th.

Rochdale.—Twelve months' supply of static transformers. Borough Electrical Engineer.

Wiring

Aylesbury.—Town Hall. Borough Electrical Engineer.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Ashton-under-Lyne.—Billiard saloon and shops. T. Calverley.

Miscellaneous

Australia.—The Sydney Corporation requires a supply of electric incandescent lamps. Commonwealth Offices, 72 Victoria Street, S.W. September 23rd.

South Wales.—Supply of electrical goods for Powell Duffryn Steam Coal Co. Secretary, 101 Leadenhall Street, London, E.C. September 8th.

West Ham.—Three months' supply of electrical fittings for Union. Clerk, Union Road, Leytonstone. September 2nd.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son of 5, Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £79 10s. to £80 10s. (last week £83 to £84).

"Century" Motors.—The agency for the "Century" single-phase motors has been acquired by the Swedish General Electric Ltd., Norfolk House, Cannon Street, E.C. (the London House of the Allmäna Svenska Elektriska Aktiebolaget of Västerås, Sweden) and the London stock of "Century" motors is now under their control. This department is being carried on by Mr. R. A. Marples, who for many years has represented the Century Co. in the United Kingdom.

Agency.—An agent at Lyons wishes to represent a United Kingdom manufacturer of electrical apparatus. Secretary, British Chamber of Commerce, 9 Rue des Pyramides, Paris.

Adnil Electric Co., Ltd.—In consequence of the decision of a Court of Appeal (ELECTRICAL ENGINEERING, June 10th, p. 247) that owing to the constitution and control of this

company—the directors being resident and the bulk of its share capital being held in Germany—it can no longer effectively carry on its business, a winding-up order has been made on the petition of a creditor. Mr. J. H. Stephens, of Messrs. Lescher, Stephens & Co., 6 Clement's Lane, London, E.C., has been appointed special manager pending the meeting of creditors, which will be held when the Courts reopen after the Long Vacation, and the services of Mr. S. G. Leach, one of the managers of the company, have been retained for the present. As mentioned elsewhere, the other manager, Mr. R. H. Marples, has joined the Swedish General Electric Co.

APPOINTMENTS AND PERSONAL NOTES

The estate of the late Mr. C. E. Spagnoletti is valued at £35,070.

An assistant electrical and mechanical shift engineer is required at the West Derby Union Hospital, Alder Hey, Salary, £2 per week. Clerk, Union Offices, Brougham Terrace, Liverpool.

Mr. W. Morgan, Professor of Automobile Engineering at the University of Bristol, has been liberated from his professional duties for the period of the war to take up munition work.

Instrument makers are required for urgent Government aeroplane work (see an advertisement on another page).

The Manager of a chemical works requires an assistant (see an advertisement on another page).

A switchboard attendant or improver is wanted at Perth (see an advertisement on another page).

LOCAL NOTES

Dundee: *New Connections Refused.*—The Electricity Department has given notice that owing to shortness of staff it is impossible to connect new consumers. Firms engaged on war contracts, however, will be dealt with.

Glasgow: *Electricity Committee's Report.*—We indicated a few weeks ago that the Electricity Department would show a loss of £459 on last year's working. The accounts themselves are now before us, and we see that this compares with a surplus of £819 on the previous twelve months. The revenue increased by £27,058, despite the abnormal conditions, but the working expenses increased by £17,621, principally due to an advance in wages to the men, a general overhaul of plant and mains, increased rates and taxes, and to a sum of £3,144, allowances to men on active service. A considerable increase in the contribution to the working fund has also to be noted on the additional borrowings, part of which is not as yet remunerative. As already stated, the charges for all classes of supply has been increased by 15 per cent. A gas-producer is being installed at the Port Dundas power station, and tests on gas firing of boilers are to be carried out. Work on the new Dalmarnock power station has been stopped during the war.

Hove: *Satisfactory Electricity Progress.*—The first year's working by the municipality of the old Hove Company's electric supply undertaking shows a net profit of £3,023. There was, however, a small deficit on the Aldrington undertaking, for which current is obtained in bulk from the Brighton Corporation, and the net profit on the two undertakings is reduced to £2,876.

Huddersfield: *Hired Arc Lamps.*—The local Chamber of Trade has been discussing the position of traders who have agreements with the Electricity Department for arc lamps on hire. Owing to the restriction of lighting, of course, these lamps have not been used, and the Corporation had charged half the amount with the agreement. This was objected to as there has been only six weeks' use of the lamps this year, and a settlement has been come to on the understanding that if half the charge is paid for the June half-year, no further charge will be made until the lamps are taken into general use again.

Ilkley: *Power Station Opened.*—The electricity supply works erected by the Council were formally opened last week. The capital expenditure contemplated upon the scheme is

£21,000, but at present only half of the plant has been installed. The remainder is on order. The present equipment consists of two 100-kw. generating sets.

Surbiton: *Transfer of Electricity Undertaking.*—The agreement for the transfer of the Council's electricity undertaking to Callender's Cable & Construction Co. has been sanctioned and the consent of the Board of Trade to the transfer is being sought. The Company has hitherto worked the undertaking on behalf of the Council.

Watford: *A Wiring Dispute.*—A case of some interest to electrical contractors came before the Watford County Court last week, when Mr. J. W. Russell claimed £41 17s. for work done at a private house in Bushey. The customer refused payment until the work had passed the Council's test, but as apparently no arrangement had been made for the electrical contractor to supply and fix fittings, the test obviously could not be made. The Borough Electrical Engineer gave evidence to the effect that so far as the work was completed it complied with the requirements of the Electrical Department, and in view of the fact that no arrangement had been made between the contractor and the customer for fittings, a verdict for the former was given.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

W. T. Henley's Telegraph Works Co.—An interim dividend at the rate of 10 per cent. per annum, less tax, is declared upon the ordinary shares for the June half-year (last year the same).

London Supply Companies' Dividends.—The Brompton and Kensington Electricity Supply Co. announces an interim dividend on the ordinary shares at the rate of 9 per cent. per annum, less tax, for the June half-year (last year the same).

The Electrical Trades Benevolent Institution.—Owing to the war, the Annual Festival of the Electrical Trades Benevolent Institution will not be held this year. Sir David Salomon, President of the Institution, has issued a letter pointing out that the cancellation of the Festival deprives the Fund of its chief source of income at a time when very heavy demands are made upon its resources. In these circumstances, he continues, the Committee confidently rely upon subscribers to renew their contributions upon an even more liberal basis than in past years. They also hope that the urgency of the claims made upon the Fund will bring a large influx of new subscribers.

—OUR BOOK— DEPARTMENT.

Technical Books by all Publishers sent carriage free to any address in the United Kingdom at net published prices.

Orders should be addressed to the KILOWATT PUBLISHING CO., LTD. (Publishers of *Electrical Engineering*), 203, Temple Chambers, London, E.C., and should be accompanied by a remittance.

SUMMARY

THE arrangements for the centralisation of power supply to the London Underground Railways are well advanced. The City and South London Line is already run from Lots Road, and a similar course is to be taken in the case of the Central London Railway (p. 354).

THE advisability of setting the armatures of motors purposely a little out of centre is discussed in our "Questions and Answers" columns (p. 355).

A BOOK on Indian Electrical Engineering is reviewed (p. 355).

AMONG the subjects of specifications published by the Patent Office last Thursday were accumulator cells, incandescent lamps, variable speed A.C. motors, and wireless telegraphy. Application has been made for the suspension of two enemy-owned patents relating to electric bells. Patents on magneto ignition, electro-chemical processes and train lighting expire during the current week after a full life of fourteen years (p. 356).

A SHORT article sums up a few of the requirements which will have to be met if the electrical trade with South America, formerly held by Germany, is to be captured by our manufacturers (p. 357).

THE electrical equipment at a ball-bearing factory is described in an illustrated article (p. 357).

A REGULAR commercial wireless telegraph service

between Japan and the United States is soon to be opened (p. 357).

RECENT developments in heating and cooking apparatus, induction motors and fittings and accessories are referred to on pp. 358 and 359.

A 5,000 kw. and a 10,000 kw. turbo-generator are required at Shanghai; power station plant in Australia; H.T. mains at Stretford; battery at Horsham; telephone cable in New Zealand; and electric cranes at Sydney (p. 359).

MOTORS, heaters, and cookers will shortly be hired out at South Shields.—There has been a fire at the Belfast Electricity Works, due to an accumulation of gas over the coal bunkers (p. 360).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING SEPTEMBER 4TH, 1915,
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday.—Drills, 6.30 to 7.30. Section 1, technical instruction. Sections 2, 3, and 4, squad drill, musketry, or signalling.

Wednesday.—No drill.

Friday.—Drills, 6.30 to 7.30. Section 3, technical instruction. Sections 1, 3, and 4, squad drill, musketry, or signalling.

Saturday.—2.30, promotion class. (Members wishing to join signalling class are requested to give in their names to their Section Commanders.)

Musketry.—Arrangements are being made for the various sections to go through a course of instruction at the miniature ranges in Greycoat Place; final particulars will be published later in supplementary orders.

E. G. FLEMING,
(Company Commander and Acting Adjutant.)

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

Through A. Campbell Swinton, Esq., who is a director of Messrs. Crompton, Ltd., this firm has offered to the Corps a 24-in. projector barrel and stand, which has been accepted.

The Corps is still open for suitable recruits, either from members of the engineering institutions, or from others who desire to join an engineering unit and take advantage of the training available at the headquarters of, and under the staff of, the London Electrical Engineers (T.F.), who have kindly given every facility to this corps. Applications to Lt.-Col. C. B. Clay, V.D., M.I.M.E., M.I.E.E., Marconi House, Strand, W.C.

Capital Restrictions.—It is stated that in cases where extensions to electricity undertakings are imperative for the supply of power to firms engaged on war work, the Treasury has arranged with the London County Council to abandon many of the usual red-tape preliminaries in order that loans can be granted without delay. This applies, however, only to firms engaged on work directly concerned with the War Office or Admiralty.

POWER SUPPLY ON THE LONDON UNDER-GROUND RAILWAYS

ONE of the most important of the economies which have been rendered possible by the grouping of most of the underground electric railways of London under one administration is the possibility of supplying the whole of the lines from a single power-house equipped with large and economical generating units instead of the separate lines being supplied from their own stations on a smaller scale on which so high an efficiency was not attainable. The two pioneer tube lines, the City & South London and the Central London, have now for some time been under the control of the London Electric Railway Co., and already the former takes its power from the great station at Lots Road, Chelsea; while arrangements for the running of the Central London Railway from the same source are about to be made. The Lots Road station will then supply the whole requirements of the District, the Bakerloo, Piccadilly, Hampstead, City & South London, and Central London Railways, as well as a portion of the London United Tramways. The City & South London station at Stockwell has already been shut down, and before long the Shepherd's Bush station of the Central London will endure the same fate. A similar history befell the Great Northern & City Railway on being taken over by the Metropolitan Railway, resulting in its being now run from the large station at Neasden, which supplies the whole of the electrically-worked portion of the Metropolitan Railway. Thus the only underground line running from its own small station is the short Waterloo & City line, but it would surprise no one to learn that on completion of the London & South Western Railway Co.'s own large station near Wimbledon that the last of the historic small traction stations was to be shut down. The Great Western Railway have, of course, their own station at Park Royal, and the London & North Western Railway generating station at Stonebridge Park is fast approaching completion. This and the L. & S.W. station already referred to are already planned on a considerable scale, and may later be extended to a size unthought of at present as the success of the tentative schemes which they represent becomes fully demonstrated. It is, however, more particularly the change-over of the City & South London Railway that we wish to speak of now.

The City & South London Railway has a history of greater interest technically than any of the other lines of the group, in that it was the first electric "tube" railway in the world, and later presented the first example of three-wire distribution for traction. Opened in November, 1890, with a length of three miles, the line took its power originally from its own station at Stockwell, which contained what were then described as "three large Edison-Hopkinson dynamos" of an output of 202 kw. each, rope driven with the aid of jockey pulleys by Fowler vertical engines. This original station was later superseded by a new one almost alongside it, in which were installed originally two 800-kw. E.C.C. dynamos driven by slow-speed Cole, Marchent & Morley engines, and subsequently four Willans & Robinson engines, two of 500 h.p. and two of 210 h.p., also driving E.C.C. generators, a 550-h.p. Ferranti engine, and a Lentz 1,000-h.p. engine driving two generators. This brought the capacity of the station up to almost 4,000 kw. Originally, the track was fed direct at 500 volts, but with the extensions of the line to Islington and Clapham in 1900 and 1901 a higher transmission voltage was advisable, and the line was arranged as a three-wire system with 1,000 volts on the outers and the neutral earthed. Balancers and buffer batteries controlled by Highfield boosters were also installed in sub-stations. In connection with the northern end of the line, the equivalent of a five-wire system was employed by putting motor-generators in series with the pairs of 500-volt machines already in series in the station and transmitting at 2,000 volts to sub-stations at London Bridge and Islington, where further motor-generators converted back to the 2 x 500 volts at which the track was supplied. These arrangements continued in force until the moment of the change-over on June 13th, when power was first taken from Lots Road. For this purpose new 11,000-volt three-phase feeders were laid through the various tunnels from Lots Road to rotary converter sub-stations at Euston, Old Street, Elephant, and Stockwell; an additional 1,200-kw. rotary converter was put in at the Euston sub-station, which also feeds the Charing Cross, Euston & Hampstead Railway. The switchboard in this and the other combined sub-stations is arranged with the L.T. bus-bars divided so that the City & South London circuit is fed by separate machines, as the return is uninsulated and the track voltage is slightly lower. At the new Old Street sub-

station four 800-kw. rotary converters have been installed, and at the Elephant, which also feeds part of the Bakerloo line in place of the former sub-station at St. George's Circus, there are four 1,200-kw. sets. The new Stockwell sub-station, in a new building adjoining the old station, is not quite complete; it will contain two machines of the smaller size brought from Euston and two from St. George's Circus. All the new rotary converters, transformers, and switchgear in the sub-stations was supplied by the British Thomson-Houston Co. Pending the completion of the Stockwell sub-station, the southern end of the line is being fed from the Elephant, and an existing booster has been connected up temporarily to avoid an undue drop of pressure. When all this plant had been got ready, the actual change-over was a simple matter. Links were put in connecting up the new track feeders, and the new sub-station plant was run up on the morning of June 18th, while the old track-feeder switches were left open. In event of trouble, the old station could have been run up and put on the load without delay. Subsequently the old feeders have been disconnected, and the old station is ready to be dismantled when a purchaser is found for the plant. The sub-station batteries have been kept in commission for emergency lighting and lift operation. The ordinary lift and lighting circuits have been changed over to the new sub-stations in a similar way to the traction circuits. The whole of the station lighting is electric, and the gas lighting formerly relied on for emergencies has been removed. The scheme for enlarging the tunnels of the City & South London line and relaying the track to take the standard rolling stock as used on the other tubes has been temporarily abandoned owing to the war.

The problem of the conversion of the Central London Railway to supply from Lots Road will be met in a slightly different way. 11,000-volt feeders will be taken to Shepherd's Bush and transformers installed to reduce the pressure to 6,000 volts, which is the present generating pressure there. The frequency of the Lots Road supply is, however, different from that at Shepherd's Bush, being 39 $\frac{1}{2}$ instead of 25 cycles, and this will be met by making certain alterations to the rotary converters which will enable them to run at the correspondingly higher speed. It will be remembered that the Shepherd's Bush station, originally opened in 1900, represents the American practice of the time immediately preceding the steam turbine era, and contained six 800-kw. alternators run by slow-speed American engines, a 2,000-kw. alternator driven by a Musgrave horizontal engine was added later. It is interesting to note that the whole output of this station can be dealt with by a single turbine of the size in use at Lots Road. Historically the Central London is almost as interesting as the City & South London undertaking, as it was the first railway in this country to be run with a track voltage in the neighbourhood of 500 volts obtained from rotary converter sub-stations fed by a three-phase supply—a system which, with the exception of the single-phase lines of the London Brighton & South Coast, is now adopted on the whole of the electric railways and tramways in and near London.

Of the reduction in costs per unit consumed that is expected to be realised by the centralisation of power supply outlined above it is impossible to give any figures. The secret of the actual generating costs at Lots Road has always been carefully guarded. Nor is it necessary here to describe the equipment of the famous station in detail. It contains at present eight turbo-alternators rated at 6,000 kw., but capable of considerable overload capacity, and it is an open secret that a new 15,000-kw. turbo-alternator is practically complete, and that there is floor space for another set of like magnitude. (Some notes on the Lots Road power-house were given in ELECTRICAL ENGINEERING, Vol. IX., p. 341, June 12th, 1913.)

It should be mentioned that the arrangements for the changes in the power supply are in the capable hands of Mr. P. V. McMahon, who for many years was Engineer to the City & South London Railway, and on the taking over of that line, assumed the duties of Superintendent of Power in connection with Lots Road and Shepherd's Bush generating stations. It is through his courtesy that we have been enabled to put these notes together.

Defence against Torpedoes.—Mr. Emile Guarnini, writing from Geneva, tells us that he has devised an electrical system whereby torpedoes from submarines can be caused to deviate from their course and to explode prematurely. The invention is being submitted to the Governments of England, France, Russia, and Italy, and is said to be applicable to the defence of any ship.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practise. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,457.

I HAVE an electric drill, $\frac{1}{2}$ in. capacity, 110 volts, single-phase, squirrel cage rotor, and wish to run this off either A.C. or D.C., same voltage. The rotor has been wound and fitted with a commutator, and the machine runs fairly well as a repulsion motor, but does not develop full torque. As a series D.C. machine it gets excessively hot, after a few minutes' run; have tried various means of keeping cool, such as fans, &c., but without success. Are there any means I can adopt to enable this machine to be run satisfactorily as a repulsion or series machine on A.C. or series, or shunt on D.C. The frequency of A.C. supply is 60.—W. E. L. (Canada).

(Replies must be received not later than first post, Thursday, Sept. 2nd.)

ANSWERS TO No. 1,455.

Is it usual to make the air-gap length of large D.C. and A.C. motors and generators equidistant under all poles of a given machine, or is the gap less under the top poles? If the latter is the case, why is it done? How much is this reduction for various sizes and types of machine, and what calculation is this reduction based upon? What method is employed to set the machine out of centre?

The first award (10s.) is given to "A. R. T. C." for the following reply:—

In the earlier days of electrical engineering it was frequently proposed in erecting machines to make the top gap less than the bottom gap, so that the unbalanced magnetic pull would compensate, more or less, for the weight of the armature, thus reducing wear on the bearings. This idea was sometimes carried out, but the writer has not come across any modern machines so erected, nor does he know of any firm which now uses the method. There are several reasons why the idea would be inadvisable on modern machines. In the days of bipolar machines, setting the armature eccentrically did not result in unbalancing either electrically or magnetically. With multipolar machines unbalancing does take place. It is true that the armatures are usually provided with equalisers, but modern machines have been cut so fine that very often the equalisers have sufficient to do in compensating for the unavoidable variations found in the material, &c., without aggravating matters by decentralising the armatures purposely. Further, the mechanical design of machines has improved greatly, so that it is not a troublesome matter to take up wear in the bearings. Regarding alternators, there is no unbalancing caused by eccentricity of the armature, as may be seen by inspection of a winding diagram. The writer, however, has not come across any cases where the idea is carried out. With turbo-alternators there is practically no wear on the bearings, as forced lubrication is generally adopted. In induction motors the air-gap is made as small as possible, the limit being due to mechanical reasons. To decentralise the rotors, therefore, the gaps would require to be increased, thus

lowering the power factor of the machines, which is not desirable. The effect of eccentricity of rotors is discussed in most of the standard text-books, and approximate formulae are available, from which the magnitude of the unbalanced magnetic pull can be calculated.

The second award (5s.) is given to "W. H.," who writes as follows:—

In reply to the first portion of the query, I would state that it is customary to make the air-gap under the main poles of A.C. and D.C. motors and generators of the same length. There are occasions when the air-gaps under the poles at the top of the machine are made slightly shorter than those under the poles at the bottom of the machine. This is done so that the first wear of the bearings will tend to equalise the air-gap lengths, so that by this means machines such as induction motors, where the air-gaps are very small, will have a longer life before bearing renewals become necessary. As, however, the permissible wear in a bearing is only a few thousandths per inch of diameter, it will be seen that very little advantage is to be obtained in the D.C. motors and generators, where the air-gap is comparatively long. It is impossible to give any definite ruling as to the difference allowable between the lengths of the top and bottom air-gaps, but it can be made equal to half the permissible wear of the bearing, say half a hundredth for each inch of shaft diameter. In order to obtain these different air-gap lengths there are several common methods; one or two well-known firms, instead of turning a close-fitting spigot on the end shield, allow sufficient clearance to enable the air-gap to be altered by means of adjusting screws. This, of course, only applies to end-shield bearing machines. In other cases a packing piece or shim may be inserted between the top pole-pieces and the frame. This is the least satisfactory method, as the "grading" of the air-gap cannot be adjusted very nicely. In the case of pedestal bearing machines, the bearings are mounted on packing pieces or shims of the requisite thickness to raise the rotor through the necessary distance, the air-gap, of course, being checked in the usual manner by means of feelers.

REVIEWS OF BOOKS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

Electrical Engineering in India. By J. W. Meares. 517 pp. $8\frac{1}{2}$ in. by $5\frac{1}{2}$ in. 74 figures. (Calcutta: Thacker, Spink & Co.; London: W. Thacker & Co.) 15s. net; abroad, 15s. 9d.

The title of Mr. Meares's book takes our thoughts back to a dear old gentleman of Dutch nationality whose English would have been nearly perfect if there had been no prepositions. Years before his death he had become famous for the following remark to a guest who had only been able to arrive after dinner: "We were eleven on the table, and we regretted that you were not under us." If we except the title, the grammar of Mr. Meares's book is perfect, but it should have been labelled "Electrical Engineering for India," and not "Electrical Engineering in India." The Indian reader will, to be sure, find in it exactly what he expects, namely, a practical book of electrical engineering with the conditions peculiar to India always in view. On the other hand, the English electrical engineer who is led by the name of the book to anticipate a description of electrical plant and engineering methods in India, with highly technical practical advice as to the modifications which should be made in home practice in design, construction, and erection to meet Indian conditions, will be disappointed. The work is, in fact, primarily intended to give civil engineers of the Indian P.W.D. and students destined for the service a useful knowledge of electrical engineering. Incidentally it also serves to some extent as a price book, as the cost of various items of electrical plant and accessories in India are included in some of the tables of sizes.

A few errors (chiefly due to the Indian printers) and omissions are almost inseparable from a book of this character written away from home, but they are not of such importance as to impair the utility of the work to any serious extent. On the other hand, many writers in England might follow Mr. Meares's lead with advantage in the choice of matter for a technical book dedicated directly to the practical worker.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 19th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

2,548/14. Accumulators. VAN RADEN & Co., LTD., and M. MERZ. Accumulator cells, more especially intended to supplement celluloid for use in hot climates, made of a lead-antimony alloy with a cover of glass, through which the interior of the cell can be inspected where there are holes in the lead framework. (Six figures.)

3,209/14. Incandescent Lamps. C. GLADITZ. Lamps with a filament support of silica of substantially triangular section, but with concave surfaces, round which is wound a wire filament previously coiled into a tight helix. (Three figures.)

4,803/14. A.C. Motors. PHOENIX DYNAMO MFG. Co. and R. POHL. A variable-speed A.C. motor for driving winding engines and other work in which both the inner and outer members are capable of rotation. Each is connected mechanically and electrically with the armature of an auxiliary machine having a series characteristic, and the speed regulation is effected by controlling the fields of the auxiliary machines by diverters. (One figure.)

11,621/14. Lamp Repairing. BARON A. O. VON BÁTOKÉZ UND VERINKHÁZ. A machine for cutting off the lower part of used lamp-bulbs in order to replace the filaments. The lamp is gripped by a self-centring holder and rotated, and provision is made for making a scratch by a diamond and causing alternate blasts of hot and cold air to impinge upon the part to be cut. (Four figures.)

12,259/14. Wireless Telegraphy. W. J. MELLERSH-JACKSON (*Fratelli Marzi di G.B.*). A device for the continuous production of sustained oscillations by means of a "crackling" arc between a rod electrode and an electrode in the form of a rotating metal drum kept moist by a jet of liquid. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: LIBANO [Insulator for overhead lines] 12,443/14; BEAVER and CLAREMONT [Cables] 19,882/14; W. T. HENLEY's TELEGRAPH WKS. Co., LTD. [Distribution] 6,117/15.

DYNAMOS, MOTORS, and TRANSFORMERS: SIEMENS BROS. DYN. WKS., LTD., and KIEFFER [Rotors] 14,278/14; SIEMENS BROS. DYN. WKS., LTD. and KOETTGEN [Starting rotary converters, &c.] 14,378/14; MEIROWSKY & Co. and FISCHER [Transformers and other high-tension apparatus] 14,483/14; SIEMENS BROS. DYN. WKS., LTD., and KIEFFER [Windings] 15,958/14; ANDERSON and ATCHLEY [Speed control] 22,897/14.

Ignition: RALL [Sparkling plugs] 14,561/14.

Incandescent Lamps: GLADITZ [Incandescent lamps] 13,541/14; TRENNEN [Rendering tungsten ductile] 14,381/14; A.E.G. [Incandescent lamps] 18,566/14; GLUHFÄDENFABRIK AARAU A.G. [Ductile tungsten] 23,496/14.

Instruments and Meters: SZILARD [Electrometers] 16,945/14.

Switchgear, Fuses and Fittings: SIEMENS BROS. DYN. WKS., LTD. (*Siemens-Schuckertwerke*) [Cartridge fuses] 12,210/14; MELLERSH-JACKSON (*Geb. Jaeger*) 12,682/14; SIEMENS-SCHUCKERTWERKE [Starters and controllers] 17,949/14; B.T.-H. CO. YOUNG and WATSON [Relays for voltage regulators] 18,497/14; SIEMENS-SCHUCKERTWERKE [Switches] 18,502/14; B.T.-H. CO. (*G.E. Co., U.S.A.*) [Resistances] 18,685/14; B.T.-H. CO. (*G.E. Co., U.S.A.*) [Circuit breakers] 21,785/14; IGRANIC ELEC. CO. (*Cutler-Hammer Mnf. Co.*) [Motor controllers] 23,366/14; MELLERSH-JACKSON (*Soc. Anon. Moro*) [Circuit breakers] 24,039/14; MARKT [Switches and couplings] 6,222/15.

Telephony and Telegraphy: SIEMENS BROS. & Co., LAIDLAW and GRINSTEAD [Telephone exchange circuits] 3,902/14; SIGNAL GES. [Wireless radiating system for aeroplanes] 13,520/14; SIEMENS BROS. & Co. (*Siemens & Halske*) [Telephone circuits] 15,471/14; SIEMENS BROS. & Co., PETTIGREW & CHRISTIAN (partly *Siemens & Halske A.G.*) [Telephone circuit selecting

devices] 15,546/14; DEUTSCHE TELEPHONWERKE [Wireless detector] 15,881/14; BLESSING [Telephone systems] 18,033/14; BLOXAM (*Telepantograph Ges.*) [Writing telegrapher] 18,290/14; SIEMENS BROS. & Co. and PETTIGREW [Automatic telephone circuits] 18,565/14; STERLING TELEGRAPH & ELECT. Co. and WARD-MILLER [Telegraph key] 5,089/15.

Traction: SIEMENS BROS. & Co., LTD., and Boor [Railway signalling] 11,715/14; SIEMENS BROS. & Co. (*Siemens & Halske*) [Signalling] 11,940/14; SIEMENS-SCHUCKERTWERKE [Regenerative braking] 13,136/14 and [Tightening overhead conductors] 13,213/14; GES. FÜR ELEKTRISCHE ZUGBELEUCHTUNG [Train lighting] 13,553 and 13,554/14; SCHUSTER [Railway signalling] 14,136/14; SIEMENS-SCHUCKERTWERKE [Tensioning arrangements for overhead conductors] 14,683/14; SIEMENS BROS. & Co. (*Siemens & Halske A.G.*) [Control of points] 15,642/14; THOMPSON [Signalling] 18,433/14.

Miscellaneous: RALPH [Gas detection apparatus for mines] 10,110/14; NORMA COMPAGNIE [Magnetic chucks] 11,993/14; A.E.G. [Electric welding] 12,479/14; ANSCHÜTZ & Co. [Gyroscopic compasses] 12,959/14; SIEMENS-SCHUCKERTWERKE [Searchlight projectors] 13,920/14; SIEMENS BROS. & Co. (*Siemens & Halske*) [Interrupting devices] 15,871/14; SIEMENS-SCHUCKERTWERKE [Signalling arrangements for searchlights] 18,123/14; COLLEY [Electric hoisting apparatus] 18,302/14; SIEMENS BROS. DYN. WKS., LTD. [Distant control of searchlights, guns, and other apparatus] 18,466/14; RAILING and ANGOLD [Reflectors for miners' lamps] 22,227/14; B.T.-H. CO. (*G.E. Co., U.S.A.*) [Vibrating rectifiers] 23,121/14; ADICKES [Binding posts] 24,429/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Switchgear: R. BOSCH [Pedal switches] 2,236/15.

Traction: SOC. ANON. DES ÉTABLISSEMENTS L. BLÉRIOT [Vehicle installations] 8,466/15; BETHENOD [Lighting magnetos].

Miscellaneous: MÖLLER [Separation of dust, &c., from gases] 11,088/15.

Application for Suspension of Enemy Patents

27,457/07 and 19,199/10. **Electric Bells.** C. HERRDE. An application by J. Warner & Sons will be heard on Sept. 1st. The first of these specifications describes mechanism for large electric bells with heavy hammers, and the second describes a separate periodic contact maker and breaker for this class of apparatus.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

17,249/01. Magneto Ignition. F. R. SIMMS and R. BOSCH. Magnets with stationary armature and field magnets, and a moving inductor sleeve surrounding the armature.

17,520/01. Electrochemistry. P. E. C. CORBIN. Electrochemical production of chlorates, perchlorates, bromates, iodates, &c., from solutions containing chromic acid.

17,482/01. Train Lighting. A. B. GILL. A number of improvements in detail of a previously patented electric train lighting system.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS and TRANSFORMERS: C. A. PARSONS, A. H. LAW, and J. P. STOCKBRIDGE [Commutators] 10,588/09; A. E. G. [A.C. motors] 10,663/09.

Instruments and Meters: SIEMENS BROS. & Co., E. F. LAUKERT, and J. NEBEL [Instrument switches] 10,550/09.

Switchgear, Fuses and Fittings: FELTEN & GUILLAUME LAHMEYERWERKE [Protective system] 9,844/08.

Telephony and Telegraphy: G. C. M. HARDINGHAM (*Felten & Guillaume*) [Loaded telephone cables] 10,296/03.

Traction: W. KÖHLER [Overhead collectors] 26,807 and 26,808/09.

Miscellaneous: A. C. E. RATEAU [Control of electrically-driven centrifugal feed pumps] 7,999/05; G. WOLTERS [Electric miners' lamps supplied by self-contained dynamo driven by compressed air] 10,312/09.

TRADING WITH SOUTH AMERICA

A N. article in the *Electrical Record* (Canada), which has been sent us by Mr. F. A. Cambridge (City Electrician, Winnipeg), deals with the situation as regards electrical trade with South America. One of the principal characteristics of the Latin population of the South American States, in the author's opinion, is that he would rather pay an increased 10 per cent. in price and enjoy a six months' credit, than to be deprived of this credit and compelled to pay cash. The inability to recognise this trait, and the refusal to humour it as other nations have done, is one reason why we are not getting the benefit of the South American trade at present. Nearly all the electrical apparatus in use is of European manufacture, mostly German, though a quantity of French, Belgian, and British material is used. The United States is represented by the General Electric and Westinghouse Co.'s who do considerable business. The bayonet lamp socket and base are used in preference to the Edison. American manufacturers are now making great efforts to capture the trade, at any rate temporarily lost by Germany. With regard to the electric supply situation, with the exception of the very powerful companies controlling the electrical supplies of Buenos Aires and Montevideo, which are German, the larger part of the balance is controlled by British capital. The Lacroze Co. in Buenos Aires, controlling a large electric and steam railway service, is native. All steam-driven stations use imported machinery, coal, oil, and other supplies.

It is highly important, continues the author, that all correspondence between the exporter and his South American client, as well as all shipping documents or other papers relating to South American shipments, should be written in the language of the country to which the goods are exported. For all, with the exception only of Brazil, Spanish is the official language. For Brazil it is Portuguese.

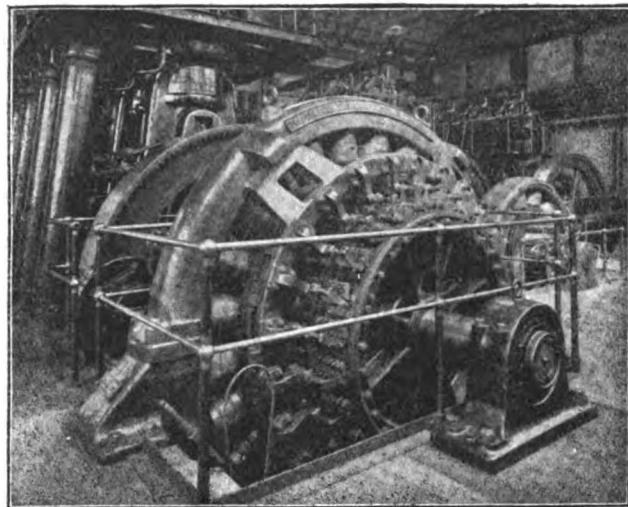

The Germans, in his opinion, have obtained and hold the electrical and many other trades in these South American countries for the following reasons: they meet the wishes and peculiarities of the people whose trade they seek; they send them literature in their own language, and give information as to dimensions, weights, and prices in the metric system; they take every care in packing, shipping, and preparation of documents, to cause the customer the least possible trouble, and conform to the local customs laws; they send representatives to interview customers and obtain their business, representatives who are painstaking, polite, indefatigable, and who speak to the customer in his own tongue, not compelling him to produce someone to act as interpreter; they have tact enough to gratify the Latin pride by extending him credit without letting him know he is paying for it; and finally, because the German ships these goods when once sold to the customer, in German ships, under the German flag, at much lower freight rates than the customer could obtain from a British ship trading between the same ports.

The British controlled this trade in 1896. In 1906, just ten years later, they had lost the greater part of it to Germany. The British had the ships, but they would not depart from established customs in business, language, currency, or weights and measures, preferring to force these upon the Latin, who was reluctantly compelled to accept them. When the German entered the field and humoured the Latin, the German promptly secured the trade. Our manufacturers, he insists, will have to pay greater attention to these matters in order to claim and hold the trade that is theirs if its acquisition is set about in the right way.

ELECTRIC SUPPLY IN A BALL BEARING FACTORY

IN the works of the Hoffmann Manufacturing Co., Ltd. (Chelmsford, Essex), power is supplied for driving the machinery at 110 volts. In consequence, the generators are called upon to supply very heavy currents. These machines are driven by Diesel engines, and in the first installation comprised two 220-kw. "Witton" generators, coupled to three-cylinder Diesel engines, having cylinder dimensions of 450 mm. diameter \times 660 mm. stroke. A recent addition to the plant took the form of a 700-kw. "Witton" generator driven by a four-cylinder Diesel engine, with cylinder dimensions of 510 mm. diameter \times 660 mm. stroke. This engine has water-cooled pistons and cylinders. Naturally, such a machine, running at the low speed of 187 r.p.m., had large dimensions, and the problems involved in its construction can be realised by the fact that the full load current of the generator is 6,400 amperes. Special care was taken in the design and construction of the commutator and brush gear, a double commutator being adopted to carry the heavy current. That the General Electric Co., Ltd., were successful in its construction is evident from the fact that the generator runs continuously throughout the week without giving the slightest trouble. An interesting feature of the

installation is the fact that the machines are equipped with "Hoffmann" roller bearings, a fact which no doubt contributed to their satisfactory performance. The generators

THE 700-KW. "WITTON" GENERATOR, FITTED WITH HOFFMANN ROLLER BEARINGS, AND DEVELOPING 6,400 AMPERES.

for this installation were supplied by the General Electric Co., Ltd., of "Witton," Birmingham, and 67 Queen Victoria Street, London, E.C.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

At an extraordinary meeting of Marconi's Wireless Telegraph Co. last week to confirm a resolution dealing with the appointment of directors, &c., Mr. G. Marconi, referring to the establishment of wireless telegraphy between the United States and Japan, said that a regular commercial service will soon be opened between these points. This brings the company considerably nearer to the completion of its general programme, viz., the establishment of wireless communication right round the world.

NEW PUBLICATIONS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

"The Rare Earth Industry," including the Manufacture of Incandescent Mantles, Pyrophoric Alloys, and Electrical Glow Lamps. By S. J. Johnstone. Together with a chapter on The Industry of Radioactive Substances. By A. S. Russell. 136 pp. 10 in. by 6½ in. 42 figures. (London: Crosby, Lockwood & Son.) 7s. 6d. net; abroad, 8s. 1d.

"Specification and Design of Dynamo-Electric Machinery." By M. Walker. 648 pp. 10 in. by 6½ in. 533 figures. (London: Longmans, Green & Co.) 32s. net; abroad, 33s. 4d.

Water-Power Development in Canada.—According to the (Canadian) *Electrical News*, within the provinces of the Dominion and excluding the North-West Territories, practically all of the Yukon and the northern and eastern portions of Quebec, it is estimated that 17,764,000 h.p. are available, this amount being inclusive, in the case of Niagara Falls, Fort Frances, and the St. Mary's River at Sault Ste. Marie, of only the development permitted by international treaties, and, further, does not contemplate the full possibilities of storage for the improvement of capacities. The developed powers, which are inclusive of all water-powers, whether for electrical production or for other uses, aggregate 1,712,193 h.p. as developed by turbines. The *Electrical Review and Western Electrician* reports that the Ontario Hydroelectric Power Commission is about to undertake an additional development of about 100,000 h.p. at Niagara, to be increased later to 250,000 h.p.

HEATING AND COOKING APPARATUS

THE new autumn list of electric heating and cooking appliances issued by Ferranti, Ltd. (Central House, Kingsway), is a very complete production. It opens with a reprint of a paper read before the Birmingham Electric Club on electric heating and cooking by Mr. R. Weaving. Two main types of electric fires are included, each in a number of different forms, embracing some very artistic as well as utilitarian designs. The cone fire employs the heating element shown in Fig. 1 mounted in some cases in the centre of a reflector, and the other type is fitted with the bar unit, with its zigzag arrangement of a helical wire held by parallel porcelain bars strung on two rods. Like the cone element

FIG. 1.—CONE FIRE ELEMENT.

FIG. 2.—IRONCLAD THREE-WAY SWITCHBOARD.

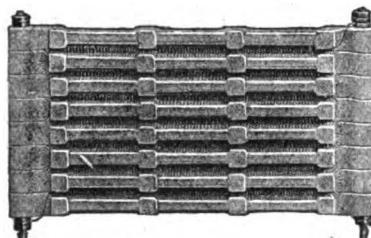

FIG. 3.—OVEN ELEMENT.

these are easily replaceable. These fires are listed up to 3 k.w.

Interchangeability of heating elements is also a feature of the cooking apparatus from the single heating plate with the well-known Ferranti disc element to the largest ovens. The number of designs of grills, breakfast cookers, ovens and complete cooking ranges already standardised, is too large to particularise here, but we may remark that all the apparatus shows a robustness, simplicity, and attention to details such as is not always to be seen. The oven element (Fig. 3) is not unlike that used in the bar fire, and particular attention should be drawn to the neatly designed switchboards such as that in Fig. 2, which are usually connected by wires in stout metallic flexible tubing to the apparatus in the case of the larger outfits.

INDUCTION MOTORS

THE latest types of two- and three-phase induction motors manufactured by the British Thomson-Houston Co., Ltd. (Rugby), ranging from the smallest squirrel-cage machines to large motors of many hundreds of horse-power, are described and illustrated in a new list just issued by the company. A great deal of useful information is included, and the patterns of machine dealt with include, besides the ordinary protected forms, with large apertures in the end shield, special drip-proof, enclosed ventilated, pipe ventilated, and totally enclosed designs, as well as a pattern with slip rings only enclosed in a flame-proof chamber. Other special machines illustrated in the pamphlet are large motors with flywheel-type rotors and pedestal bearings, and vertical shaft machines. It is noticeable that all except the smallest machines have provision for adjusting the air-gap after wear of the bearings, and a number of other patterns show the completeness with which detail has been studied in the designs. The terminal box arrangements, for example, are a great advance on what we have been accustomed to in the past. A useful graphical method is employed to indicate suitable sizes of pulleys and pinions, and the tables of dimensions, shipping specifications, &c., show the same care in their preparation as the rest of the work.

FITTINGS ACCESSORIES

THE latest catalogue published by the General Electric Co., Ltd., deals with electric light fittings accessories. In its 68 pages it illustrates and describes all the established types of accessories and a large number of novel designs of a variety which it is impossible to particularise in detail. In addition to the well-known types of "Superlux," "Holophane," and "Equiluxo" glassware, the catalogue includes a comprehensive list of cardboard, fancy silk and fancy glass

WINDOW SIGN.

shades, many of entirely new patterns. The chain section, which deals with tubes, nurls, and "S" hooks, in addition to chains, has been enlarged by the inclusion, among other novelties, of a new pattern rectangular link chain, and three patterns of Cash's ornamental patent chain. One of the most important divisions is concerned with reflectors for shop-window and show-case illumination which enable the special regulations as to not throwing light on to the pavement to be

DWARF CANDLE.

"ORDNANCE" LANTERN.

complied with while concentrating the light in the most efficient way possible. Associated with the problem of shop-window lighting is the installation of electric signs. Various types of signs are included, and special attention is given to window signs which may be used in conformity with the present regulations. These signs, of which we illustrate one example, are supplied complete with chains and ceiling plates, and are provided with an adjustable rod at the back. Different

MOTOR-CAR INSPECTION LAMP.

types of reflectors may be attached to this rod in order to bring about any desired distribution of the light, upwards, downwards, and backwards. This design makes a great advance upon the older forms of solid box with mirror lining. The development of incandescent lighting with large units has led to a demand for special lanterns. Among the many designs included in the new catalogue is the inexpensive "Ordnance" lantern illustrated here for Osram "Atmos" type

lamps for workshops and other large spaces. A new form of the well-known "Highfield" lantern, fitted with a ventilated top and special wiring arrangements, is also included, and among others is the "County" lantern for Holophane glassware. A great variety of shop fittings and outside fittings suitable for docks, wharves, railways, and shipyards are also included. Sixteen types of hand lamps are mentioned in the catalogue. A special type illustrated here is a motor-car inspection lamp, built strongly of hard wood with a loaded base, for work where an upward light is needed. Sufficient examples have now been referred to to suggest the variety of fittings and fittings accessories listed, and those mentioned and illustrated will serve to indicate their thoroughly up-to-date character. Copies of this catalogue are available for engineers, contractors, and consultants on application to the General Electric Co., Ltd. (head office, 67 Queen Victoria Street, London, E.C.).

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Australia.—The Commonwealth Department of Defence (Navy Office) requires power station plant and equipment. Tenders to Naval Dockyard, Cockatoo Island, Sydney, N.S.W., by October 25th.

Barnes.—As the price of copper has a tendency to decline the Electricity Committee has decided, on the Engineer's advice, to defer the purchase of a small quantity of cable in the hope of a further decline.

Horsham.—Extensions to battery.

Shanghai.—One 5,000-kw. turbo-generator with condensing plant, and one or two 10,000-kw. turbo-generators with condensing plant. Consulting Engineers, Preece, Cardew, Snell & Rider, 8 Queen Anne's Gate, Westminster, S.W., September 24th.

Stretford.—H.T. mains are required by the Trafford Power & Light Supply Co.; also sub-station equipment.

Wiring

Bootle.—Weights and measures department at municipal offices. Borough Engineer, September 7th.

Dundee.—Extensions to post office. H.M. Office of Works, September 8th.

Kirkcaldy.—Lighting of new sanatorium. Borough Electrical Engineer, September 6th.

Manchester.—Improvement at New Theatre, Quay Street.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Bury.—New out-patients' department at infirmary. Architect, C. R. Cooper, 20 Market Street.

Falmouth.—House in Cliff Road. Architect, A. J. Cornelius, Truro.

Mansfield.—New factory. Mansfield Shoe Co.

Paignton.—Extensions to isolation hospital (£3,000).

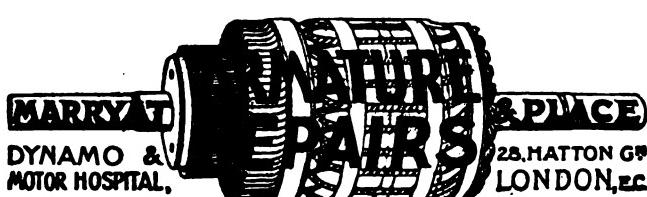

Shrewsbury.—Town hall and municipal offices.

Stretford.—Warehouse, Trafford Park Estates Co.

Miscellaneous

Australia.—The Sydney Harbour Trust Commissioners require six electrically-operated wharf capstans. Tenders to Commissioners, Circular Quay, Sydney, October 25th. Specification, &c., may be seen at 78 Basinghall Street, E.C.

New Zealand.—The Public Service Stores Tender Board,

Wellington, requires 92 miles of air-space, paper-insulated, lead-covered telephone cable, and 100 miles of insulated and braided wire.

Portsmouth.—Six months' supply of insulating materials, lamps, overhead line materials, motor windings, &c., for tramways department, August 31st. General Manager.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

London: Great Central Railway Co.—A contract has been placed with Siemens Bros. Dynamo Works for a supply of Wotan lamps.

In reference to openings for British trade abroad, attention is called to the fact that reference must be had, in dealing with these, to the various proclamations relating to export at the present time. Firms intending to follow up any openings of this description should acquaint themselves with the export position as to the particular plant referred to.

APPOINTMENTS AND PERSONAL NOTES

Mr. A. E. Wilson, Deputy City Electrical Engineer, Bristol, has been appointed by the War Office Electrical Engineer to the Chief Engineer, Southern Command, and took up his new duties at Salisbury on Monday.

Dr. A. S. McAllister has resigned the editorship of the *Electrical World* (New York), which passes into the hands of Mr. F. M. Fieker, late editor of *Factory and System* (Chicago).

A switchboard attendant is required at Blackburn (see an advertisement on another page).

The South Wales Electrical Power Distribution Co. requires a meter tester (see an advertisement on another page).

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. Geo. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £76 10s. to £77 10s. (last week £79 10s. to £80 10s.).

Consulting Engineering.—The consulting practice of Robert Hammond & Son will be carried on under the same style notwithstanding the death of Mr. Robert Hammond, but pending the return of Capt. R. W. Hammond from the Front, work now in hand and any future work entrusted to the firm will be dealt with by Messrs. Preece, Cardew, Snell & Rider.

Customs Changes.—It is announced that all apparatus used in connection with the generation and distribution of electrical energy will, in future, be admitted duty free into the Uganda Protectorate. This exemption, however, does not apply to lamps and fittings.

Change of Address.—The Automobile & Electrical Equipment Co., of 2 Kingly Street, Regent Street, W., beg to announce that their offices and showroom have been transferred to more commodious premises, Grafton House, Golden Square, Regent Street, W., with works and garage situated in Bridle Lane, Golden Square, W. (Telephone : Gerrard 1701).

The I.M.E.A. Convention.—The Proceedings of the 1915 Convention of the Incorporated Municipal Electrical Association has now been published. They contain full reports of all the discussions, together with the detailed replies of those authors who were unable at the meeting, owing to shortness of time, to more than refer briefly to a few of the points raised. The Proceedings also contains the list of members.

LOCAL NOTES

Belfast: Fire at Electricity Works.—According to daily paper accounts there has been a fire at the Corporation Electricity Works, due to an accumulation of gas over the coal bunkers, resulting in several thousand pounds worth of damage being done. We understand, however, that neither the tramway service nor the general supply to the city was interfered with.

Dartford: Increased Electricity Charges.—The proposal of the Electric Lighting & Tramways Committee to increase the charge for ordinary house lighting by 1d. per unit, long-hour users by 1d. per unit, and power users by 1d. per unit, was the subject of some discussion at the last Council meeting. The criticism was to the effect that lighting consumers are being charged a larger increase in order to pay for the power users, but it was explained that the figures of increase actually represent 20 per cent. on each class. It was pointed out to the Council that the Electricity Committee felt bound to treat the subject as a business proposition. Current is costing more, and it must either be sold at a higher price or the loss put upon the rates. The Electrical Engineer estimates that the increases will produce £625 extra revenue per annum on the lighting, £104 on the long-hour users, and £416 on the power users. The Electricity Committee's proposal was eventually carried.

King's Lynn: Electricity Accounts.—The gross profit on the electricity undertaking last year was £4,226, and, after meeting interest and capital charges, there is a net profit of £1,350.

South Shields: Hiring Out Motors, &c.—The Corporation recently obtained powers to hire out electrical apparatus, and Mr. H. S. Ellis, the Borough Electrical Engineer, in his annual report, states that good progress is being made in putting these clauses into practical effect. He hopes shortly to be in a position to hire out motors, heaters, and cookers for a nominal annual charge. There was a net surplus on last year's working of £3,216, compared with £3,484 in the previous twelve months. The sum of £1,600 has been contributed to relief of rates and the balance carried to reserve fund, which now stands at £16,335.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Victoria Falls & Transvaal Power Co.—Mr. A. E. Hadley, the Managing Director, presided at the annual meeting on Friday, when the report and accounts given in our issue for August 12th were adopted. The Chairman's speech was largely concerned with an explanation of the accounts and the general financial position of the company. Since the issue of the report the whole of the extensions of 33,500 h.p. at the Brakpan Power House have been put into commission, and the total equipment of this station will enable the company to meet any abnormal increase in the business, which, it is satisfactory to note, still continues steadily, without encroaching upon the specified reserve plant. A tribute was paid to the hard work carried out by the much-depleted staff owing to the war. The Chairman (the Marquis of Winchester) and the General Manager in South Africa (Major the Hon. W. L. Bagot) are both serving, in addition to a considerable number of the staff. After the commencement of the war Herr Rathenau (whose death we recently announced) resigned from the board.

NEW COMPANIES

FULLER'S WIRE & CABLE CO., Woodland Works, Wick Lane, Old Ford Road, Bow, E. Capital £25,000. Manufacturers of telegraph, telephone, and electric supply cables, wires, &c.

ELECTRIC SAFETY HOISTS, 17 Water Street, Liverpool. Capital £500. To take over the Star Electrical Co.'s business carried on at the above address by A. H. Colley.

SUMMARY

A PAPER by Dr. Thornton recently read in the North of England describes the use of a shunt resistance to prevent danger from sparking from mining bells (p. 362).

THE report of the Inspector of Mines for the Yorkshire district gives data of the horse-power of motors, the number of coal-cutters, and electric safety-lamps in use, and the accidents due to electricity which have occurred (p. 362).

NEW designs of flame-proof telephones and bells for mines are described and illustrated (p. 363).

SEVERAL patent specifications relating to electric miners' lamps and gas detectors have been published during the past month. Others of interest to mining electrical engineers deal with electric winder control, and signalling. There are also three specifications relating to electric furnaces (p. 364).

THE starting-up of an induction motor by direct connection to an alternator without the intervention of switchgear is discussed in our Questions and Answers columns (p. 365).

AMONG the subjects for specifications published at the Patent Office last Thursday were slip-rings, gyrostatic compasses, incandescent lamps, and writing telegraphs. Two methods of rendering tungsten ductile are also described, and a German firm has a specification for a form of searchlight specially designed for following aircraft (p. 366).

IN connection with the manufacture of munitions in London, the metropolitan police area has been divided into ten districts. The general manager is the late General Manager of the Central London Railway, whilst the district managers are for the most part electric supply station engineers (p. 366).

A NEW double-pole tumbler switch is described on p. 367.

EXTENSIONS are contemplated at St. Helens (£15,000); an electric lighting scheme is under consideration at Armagh; an electric lighting plant is required at Haslingden; meters at Johannesburg; and a large quantity of telephone parts in Australia (p. 368).

WE give a few further particulars of the fire in the coal bunkers at the Belfast electricity works.—Some figures are given of the reduced cost of street lighting in various towns owing to the war.—There was a net profit of £4,304 on the Halifax electricity undertaking last year (p. 368).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING SEPTEMBER 11TH, 1915, by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday, 6.30 to 7.30 and 7.30 to 8.30.—Section 3, technical instruction; Section 1, musketry at the miniature ranges; Sections 2 and 4, squad drill.

Friday, 6.30 to 7.30 and 7.30 to 8.30.—Section 4, technical instruction; Section 2, musketry at the miniature ranges; Sections 1 and 3, squad drill.

Signalling.—It is proposed to form a signalling class, and the names of those wishing to join should be given at once to the Section Commanders.

Good progress is being made with the Training Corps, both in drill and in the technical work for which the Corps is specially preparing itself.

Arrangements have been made for the use of a Rifle Range, and members can attend, not only at the hours of drill, but at any time convenient to themselves for practice, instructors being in attendance and rifles provided.

There are still vacancies for recruits either among those attached to the Engineering Institutions or others to whom the technical work of the Corps appeals.

Applications should be made to Lt.-Col. C. B. Clay, V.D., the Commandant of the Corps, at Marconi House, Strand, W.C.

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE session of the Royal Technical College, Glasgow, will commence on Sept. 28th, for day classes, and on Sept. 23rd for evening classes. The diploma course in electrical engineering extends over either three or four sessions. Special courses are provided in wireless telegraphy. The college is affiliated to the University of Glasgow. Particulars can be obtained from the Director.

The Session of the Faculty of Engineering at University College (Gower Street), London, begins on Oct. 4th. Intending students should communicate with the Provost not later than Sept. 15th. Full particulars can be obtained from Dr. W. W. Seton, secretary.

The courses in Electrical Engineering at Armstrong College, Newcastle-on-Tyne, which is affiliated to the University of Durham, will recommence on Sept. 27th. Special instruction in Mining Electrical Engineering can be taken. Full particulars can be obtained from Mr. F. H. Pruen, secretary.

ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

PREVENTION OF SPARKING IN MINING BELLS

A PAPER by Prof. W. M. Thornton was read recently before the North of England Institute of Mining and Mechanical Engineers on the precautions to be taken to prevent possibility of the sparking produced by the ordinary trembler bell causing ignition of gas, a subject which has been investigated by Dr. R. V. Wheeler for the Home Office (see ELECTRICAL ENGINEERING, May 6th, p. 197). Dr. Thornton discussed by the aid of oscillograms the growth of current in the inductive circuit after the "make" and the sudden high voltage produced at the break. The voltage, he continued, which causes the spark at the trembler-contact is produced by the rush of magnetism out of the coils when the current is broken. At the moment of break the battery voltage is all absorbed in the resistance, and does not affect the initial value. After the spark has ceased, the voltage across the gap is that of the battery alone. In good bells the time of break is found to be about half that of make, and the maximum voltage is about ten times that of the battery. The sparking at the trembler-contact is a series of ordinary break-sparks of short duration, in which both current and voltage are greatest at the instant of break. The igniting power of a break-spark depends on the voltage. It has been shown that the product of the least ignition current with the voltage is roughly constant. When the voltage is high, a small current becomes dangerous, and the degree of danger increases with the inductance in the circuit. With single continuous-current break-sparks on a 20 volt battery circuit, 0·5 henry causes ignition of the most inflammable mixtures of illuminating gas with a current of 0·5 ampere. Another factor of importance is the duration of the spark. It is sometimes as low as a fiftieth of the period, so that in a bell ringing twenty times a second the time of high voltage is a thousandth of a second. So short a duration is less favourable to ignition than an ordinary non-inductive break-spark, and this may account to some extent for the rarity of accidents in coal mines which might have arisen from bells. The ease of ignition of a given mixture by break-sparks as measured by the product Li (self-induction L and current i) is approximately constant. So long as the power of the bell spark does not reach the critical value the bell is safe. It is advisable to make the product Li as small as possible, for the rate of break depends to a great extent on the mechanical design and setting of the bell. It may be taken that signalling currents range on an average between 0·1 and 0·5 ampere, and the value of Li from 0·05 to 0·1. The sparking depends upon the working resistance in the circuit. The greater the resistance, the greater is the drop of voltage in the wires for a given current, and the less of it there is for the gap while the current lasts. The resistance of the spark is not independent of the current in the circuit, but it is clear that the greater is the resistance of the circuit the smaller is the sparking voltage for a given size of spark. Resistance in the battery or line, or bell-windings, therefore, diminishes the igniting power of the spark. Wet Leclanché cells having a higher resistance than dry cells are advantageous from this point of view.

For the purpose of preventing ignition of gas by a signalling bell, the first suggestion is to bridge the spark-gap by a resistance, but this may be in practice a positive danger, for by it a large part of the energy of the spark at the trembler is handed on to the signalling point on the wires. When, however, a suitable resistance is placed across the terminals of the coils, and the gap left unbridged, a break there gives rise to a spark of much less magnitude. The resistance may be always connected, or it may be so arranged that it is joined up by the movement of the armature just before break so avoiding the small current which passes continually while the bell is ringing. The resistance found to give the best results in practice varies from 20 to 150 ohms, depending on the design of the bell. This resistance provides a path for the "extra current" at break. In other words, the voltage at the spark-gap stops at the moment when it begins, for the current and magnetism in the coils die down slowly instead of being broken suddenly. The effect of the suppression of the sparking voltage is very marked. It is possible to work any bell

in full ringing in the most inflammable mixture of illuminating-gas and air without igniting the mixture while the shunt path is connected. Ignition occurs the moment that it is disconnected. By having a scraping contact in the testing chamber, it can be shown that the same increase of safety is obtained on the signalling wires as at the trembler-contact.

ELECTRICITY IN MINES York and North Midland District

THE report for 1914 of Mr. T. H. Mottram, H.M. Inspector of Mines for the York and North Midland Division, contains several references to electrical working.

The number of electrical coal-cutters in use in the district is given as 350 (including 157 disc, 87 bar, 104 chain, and 2 rotary heading machines). This is an increase of 19 over the figure for last year, and compares with 375 compressed air machines. The aggregate horse-power of motors in the 240 electrically equipped coal mines in the district is 123,648, of which 65,858 is on the surface and 57,790 underground. Of the latter, 28,699 h.p. is accounted for by haulage and 16,367 by pumping. Ventilation utilises 10,292 h.p., and winding 1,462. The motor h.p. in the five electrically equipped metalliferous mines in the district is 77 underground and 148 on the surface. A return is also given of the electric safety lamp employed, which number 88,085, made up as follows:—Bristol, 27; C.E.A.G., 24,626; Gray-Sussmann, 3,527; Joel-Fors, 453; Oldham, 6,223; and Wolf, 3,179.

The electrical accidents reported include two fatal and four non-fatal underground, and two fatal and five non-fatal on the surface, each relating to one person.

One of the fatal surface accidents, a tipper working at the screens, sustained a shock by touching a bare place on a lighting cable forming part of a 110-volt lighting, fed from tappings of the low-tension side of an 11,000/500 volt transformer, so connected that it was possible for the lighting circuit to have a potential of 500 volts above earth, as there was an earth on a part of the true 500-volt circuit.

In another case a greaser working at a bye-product coke oven stamp had attempted to switch off the current, and with one hand still on the switch touched the bare overhead wire with the other, receiving a fatal shock. Examination of the switch showed that it had become faulty in that it did not cause the blades to leave the contacts when the handle was put over.

The third fatal case was that of a coal cutter machine charge-man who, while fitting a rail to a sleeper in front of the machine received a shock from a trailing cable which was afterwards proved to be faulty, and to have the earth wire broken in two places. In reporting on this case Mr. R. Nelson, H.M. Electrical Inspector of Mines, expressed the opinion that earth conductors of trailing cables should be tested for continuity on each day before the cable is put into use. The agent of the colliery in this case was prosecuted for infringement of the regulations by having an earth conductor smaller than the minimum specified, but the prosecution failed owing to the cable having been in use before June 1st, 1911, although the coal-cutter itself had been installed since that date.

The last fatality occurred to an electrician who was splicing a cable to which current was switched on by someone who disregarded a notice that the switch was not to be touched. The management has since arranged to lock such switches while work is being carried out on the circuit.

Reference is also made in the report to the prosecutions arising out of the Wharncliffe Silkstone disaster (see ELECTRICAL ENGINEERING, Jan. 7th, p. 4). In one of the charges the manager and electrician were charged with not having an electrical cutter protected, worked, and maintained so that in the normal working thereof there was no risk of open sparking, contrary to General Regulation 132 (1).

After the explosion the coal-cutter was found not to be flame-tight, the joint between the commutator box cover and the body of the machine being so defective that a gap existed which had been caused by hammering a half-moon piece into position. In addition to this several bolts to hold the cover in position were missing. The defence was that the machine was perfect

when sent down the pit about a month before the accident, that the man in charge of the machine who was killed by the explosion ought to have put back the bolts, and that the indentation on the half-moon piece of the iron cover might have been caused by the removal of the armature on one occasion only, and was therefore of recent date. The Bench found that no criminal offence had been proved, and dismissed the charges.

There was also a prosecution of a haulage engine driver for interfering and tampering with electrical apparatus, when a fine of 10s., with £1 2s. 6d. costs, was inflicted.

FLAME PROOF TELEPHONES AND BELLS

FOR use in "fiery" mines, specially designed telephone instruments are necessary on account of the liability of inflammable mine gas being exploded should any sparking occur. The idea at first was to make the case of the instrument gas- and water-tight by employing packing between the joints, but this has not been found altogether satisfactory for the following reasons:—If the packing becomes defective (and it is difficult to maintain a perfect gas-tight joint), inflammable gas may diffuse into the instrument case and by means of a spark ignite, causing an explosion; as a result of this a part of the packing may be blown out or else the case shattered. In either event the flame reaches the outside gas, and an explosion may be brought about. Experiments have emphasised the fact that the products of an internal explosion cannot start an external explosion if they are below a certain critical temperature, so that if when an internal explosion occurs provision is made for the escape of the gaseous products in such a manner that they are effectively cooled, the problem is solved. The General Electric Co., Ltd., has given the best of its attention to such problems, and after a long period of most rigorous testing in actual practice has put on the market a flame-proof and water-tight telephone known as the G.E.C. Magneto Mining Telephone K8098 (1915

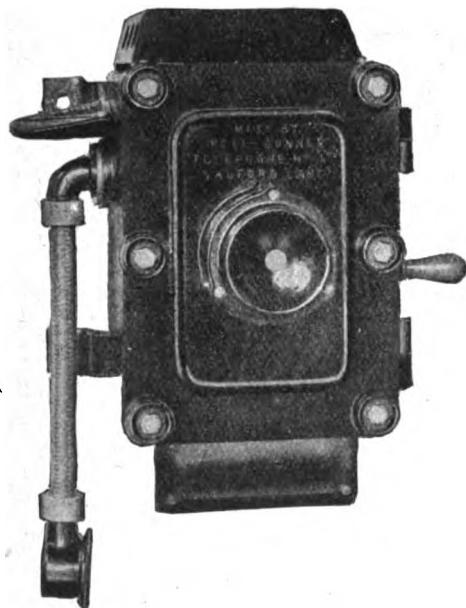

FIG. 1.—MINING TELEPHONE CLOSED.

type). This instrument is very strong and well finished. The case is of cast-iron, the joint between the case and the lid being made by machined flanges one inch wide. When the lid is bolted to the case, the joint is both water-tight and flame proof, i.e., any escaping hot gases are so thoroughly cooled in passing between the flanges that they cannot possibly ignite an explosive mixture outside the case even in the unlikely event of an internal explosion. The entire equipment is of the very highest standard, and is manufactured by the Peel-Conner Telephone Works, Ltd., of Salford, England. The internal unoccupied space is kept down to a minimum so as to limit the amount of explosive gas which might accumulate.

The equipment comprises a four-magnet tropical type generator with the armature wound to a resistance of 300 ohms, and fitted with a very strong handle working through a flame-proof and water-tight gland; a polarised bell movement wound with enamelled insulated copper wire to a resistance of 1,800 ohms and fitted with two 3-in. bell gongs, protected by an iron cover; long-distance speaking solid back transmitter

fitted in an iron chamber on the front of the lid, the diaphragm of which is protected from wilful damage by a fine-meshed brass gauze; induction coil wound with enamelled insulated copper wire, resistance of primary circuit 1 ohm, secondary circuit 25 ohms; a double-pole "bell" receiver wound to a resistance of 120 ohms is fitted inside the instrument, the diaphragm end being fitted with a cam arranged so as to revolve when the listening tube (which is placed on the left-hand side of the instrument) is lifted to the ear. The cam

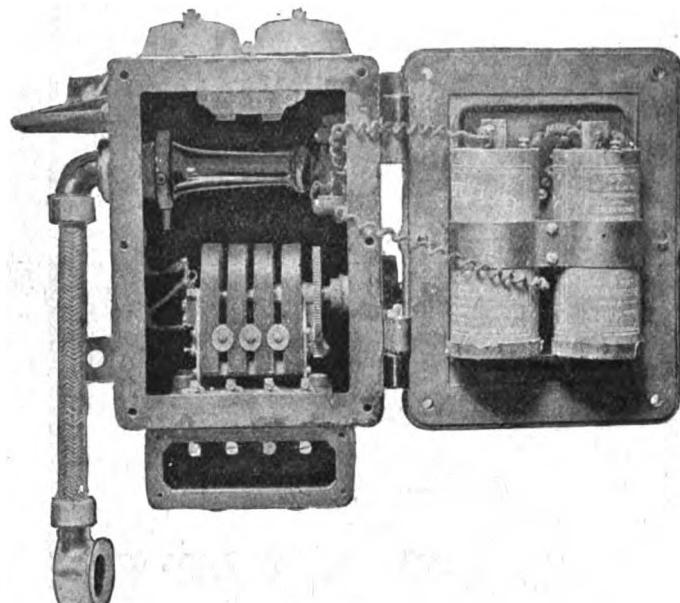

FIG. 2.—MINING TELEPHONE OPEN.

is fixed on to the receiver and revolves with it, thereby pressing together a bank of springs which control the primary and secondary circuits. The gland through which the tube passes is flame-proof and water-tight. Two No. 2 G.E.C. dry cells are fitted on the inside of the lid by means of a metal band. Attached to the bottom of the cast-iron case is a chamber which contains strong and well-designed line terminals. Four lugs fitted on the inside and back of the instrument are provided for fixing. All mining requirements are met in the best

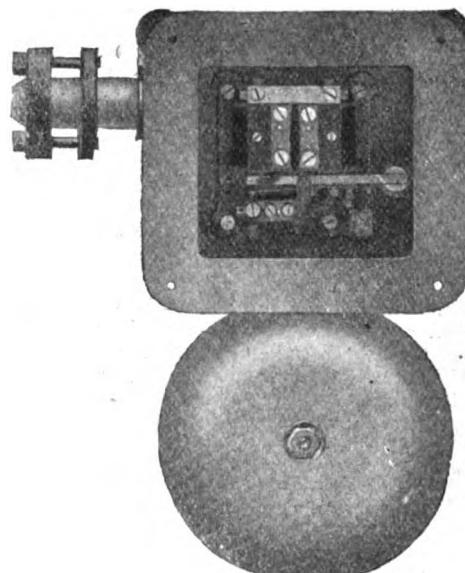

FIG. 3.—FLAME-PROOF AND WATER-TIGHT MINING BELL WITH COVER REMOVED.

possible manner, and all Home Office Regulations are complied with.

The same principles of protection are employed in the new G.E.C. flame-proof and water-tight trembling bell, illustrated in Fig. 3, which complied thoroughly with the Home Office regulations. The action is enclosed in a cast-iron flame-proof case. The lid is bolted to the case by a sufficient number of substantial bolts, and contact is made between machined flanges one inch wide. The case is water-

tight and thoroughly enamelled to prevent rusting, and the internal unoccupied space is kept down to a minimum so as to limit the amount of explosive gas which might accumulate. The hammer is connected to the armature by a shaft which passes through a gland, one inch long, in the bottom of the case. It is situated under the gong and is thereby afforded additional protection. A flame-proof gland is also fitted to the case. It is designed to take an armoured lead-covered twin cable. The bell is made with two sizes of gong, 6 in. and 8 in. respectively. The 6-in. bell weighs 14 lbs. and requires a pressure of six volts across its terminals to work it satisfactorily, while the 8-in. bell weighs 16 lbs., and requires 10 volts. The resistance in each case is 25 ohms and the current taken just under 0.1 ampere.

For further information concerning these mining telephones and bells, as well as relays, complete mine signalling systems, &c., application should be made to the manufacturers, the General Electric Co., Ltd., at the head office, 67 Queen Victoria Street, London, E.C., or at one of their provincial branches.

**ELECTRICAL MINING AND METALLURGICAL
PATENTS OF AUGUST**

Mining.

A SYSTEM of control of electric winders and electrically-driven rolling mills, where a flywheel motor-generator is used, is described by S. H. Eckmann in Specification No. 17,037 of 1914. The chief feature is that the excitation and speed of the motor-generator set is controlled automatically according to the current taken by the motor of the motor-generator.

An electric miners' lamp embodying a gas-detecting apparatus is described by W. Kraushaar in Specification No. 194 of 1914. The firedamp indicator consists of a catalytic wire with a high positive or negative temperature-resistance

coefficient, connected in series with the lamp, the luminous intensity of which is varied by the alteration of resistance of the catalytic wire when heated by the action upon it of inflammable gas.

Another specification emanating from Germany connected with miners' electric safety lamps is No. 10,674 of 1914 of W. Rossow. This inventor surrounds the lamp bulb with a double-walled glass jacket containing either rarefied or compressed gas, and connected with a device that opens a circuit-breaker as soon as the pressure of gas within the jacket is altered by breakage of the external wall, so that the lamp is immediately extinguished. The outer double glass is easily detached when required.

A signalling system for haulage roads is described by the Sterling Telephone & Electric Co. in Specification No. 4,228 of 1914, which has been communicated from Germany by the Telephon-Fabrik A.G. Vorm. J. Berliner. Insulated conductors are used, a pair of which run along the whole track and are connected at intervals to enclosed contact boxes. The contacts are actuated by cords running from each box along the track to a point half-way to the next box.

A form of combined miners' lamp and gas detector is described by G. J. Ralph in Specification No. 10,100 of 1914. The detector is of the same kind as that already patented by the same inventor, depending on the change in resistance of a previously heated catalytic wire when exposed to inflammable gas. The actual indicator, in the form of a small galvanometer, is mounted on the top of the lamp, and is arranged to give a clear indication as soon as a proportion of 2 to 2½ per cent. of gas is reached.

In 22,227 of 1914, A. H. Railing and A. E. Angold describe a reflector for miners' lamps made of springy material which can be slid in between the pillars and glass of the lamp to direct the light in any desired direction, and when not in use can be clipped on to the body of the lamp.

Electro-metallurgical.

Specification No. 742 of 1914, of F. Krupp A.G. describes arrangements in an A.C. electrode furnace for automatically mixing up the charge. The mixing movement is imparted to the molten charge by the co-operation of the heating current supplied by the electrodes and spreading out in the charge in a radial direction, and a magnetic field directed at right angles to the upper surface of the bath. Several arrangements of connections are described.

Two specifications in the name of W. E. Evans (communicated from Germany by the Elektrochemische Werke Ges.), numbered 17,425 and 17,426 of 1914, deal with electric furnaces. The first is for a special form of furnace electrode constructed to minimise heat losses and of bell or cage shape, with walls of such a thickness that at any level the cross-sections are equal. It is provided with a hollow reinforcing ring, adapted to be cooled. The cross-section is calculated so that the C_2R effect causes the end of the electrode to attain the same temperature as the molten bath. The second specification describes a method of producing a flow or circulation in the molten charge in a furnace, characterised by the fact that the conductors that are employed are disposed at right angles to one another. At least two of these are channels filled by the molten mass in the furnace, and form a closed loop or path so that the liquid is set in motion by the electromagnetic interactions.

Electrical Mining Fatality.—At the Bardykes Colliery, Cambuslang, on Aug. 17th, a man named McDougal was killed by electric shock by coming in contact with a faulty cable.

Live Rail Fatality.—A boy of seven was killed by electric shock on the North-Eastern Railway at St. Peter's, near Newcastle, last week. It appeared from the evidence at the inquest that with another boy he had climbed a wall and was trespassing on the railway when he came in contact with the live conductor rail, and fell with his face on the rail. A verdict of accidental death was returned.

Electric Power from Niagara Gorge.—According to the *Electrical World* a scheme has been submitted to the New York State authorities to construct a 90 ft. dam across the Niagara Gorge, so that the present whirlpool rapids would be replaced by a fall at the lower end of the gorge from which about 2,000,000 h.p. would be available, half for New York State and half for Ontario.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,458.

I am attending to a continuous-current electric crane designed to lift 30 tons. The figures on the name-plate of the hoisting

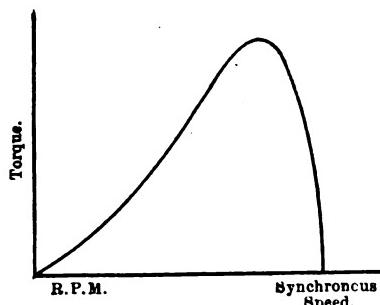

FIG. 1.
TORQUE DURING THE STARTING PERIOD OF A THREE-PHASE, SQUIRREL-CAGE INDUCTION MOTOR STARTING LIGHT.

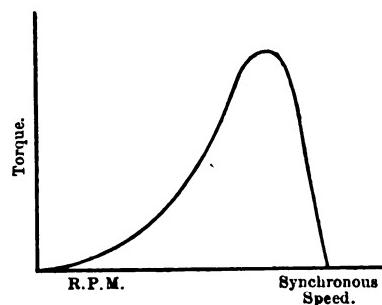

FIG. 2.

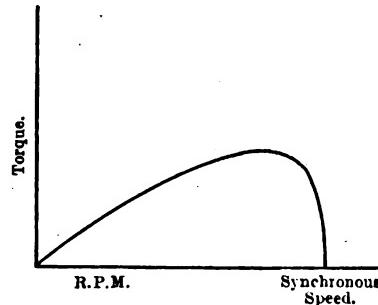

FIG. 3.

motor (which is series wound for 400 volts) are worn off. I should be glad to know what its rated horse-power and its normal and overload current is likely to be.—(H. T.)

[A lifting speed agreeing with usual practice may be assumed.—ED., E.E.]

(Replies must be received not later than first post, Thursday, September 9th.)

ANSWERS TO No. 1,458.

I wish to start up a 3-phase S.C. induction motor direct from an existing alternator without switchgear between the machines. Under these conditions, how will the torque of the motor vary with the speed? Is it necessary to separately excite the alternator field during the starting period? Are there any disadvantages in the method of starting?—M. M."

The first award (10s.) is given to "W. H." for the following reply:—

There is hardly sufficient information in the question to give a definite reply to all the queries raised. However, it is quite possible to start up a motor from an alternator without any switchgear.

(A) If the induction motor is a small machine, it would be possible to start up by simply connecting the cables to the line (assuming the voltage allows handling with gloves), and in this case the torque would rise to a maximum with increasing speed up to some point below the actual running speed, and would then rapidly fall again until the machine falls into step. That is assuming the motor starts light. The position of maximum torque relative to the speed depends upon the resistance of the rotor, viz., the higher the resistance the further away from synchronism is the maximum torque position (see Fig. 1).

(B) If, however, the motor is of any considerable size it becomes necessary to adopt other methods. The machine will require to be connected to the alternator while the line is dead.

If the induction motor has a large number of poles and is not therefore so subject to locking, it may be started up by simply bringing the alternator slowly up to speed, allowing the exciter (if direct coupled or driven from the alternator shaft) to gradually build up its own field. A very heavy current will be taken from the line and the starting torque will be very small as compared with the full load torque (Fig. 2). The torque during the starting period will vary as the square of the applied voltage and inversely as the cycles, so that the actual torque developed depends very largely on local conditions such as the time taken for starting up, &c. If the torque developed is not sufficient to start up the motor until the alternator is nearly up to speed, the flow of current into the motor may reach a dangerous value and may burn out the machine.

(C) To overcome this it will be necessary to separately excite the alternator field with its normal current and then gradually bring the alternator up to speed; by this means the voltage at the generator terminals will be much higher than before at lower speeds and the starting torque therefore much higher. With careful starting the alternator and motor may be kept practically in synchronism until right up to speed, and thus limit the current during starting to a reasonable value, even as low as full-load current. In this case the torque curve will be much flatter than before and will, of course have a higher value at starting. The disadvantage of this method of starting is, of course, the high current required to start the motor.

In method (A) the current may be five or six times full load current. In method (B) it may be three or four times, depending on the size of the motor. Method (C), of course, has the great disadvantage of requiring a separate source of direct-current supply.

The second award (5s.) is made to "E. H." who writes as follows:—

It is presumed that the induction motor in question is the only machine that is being supplied by the existing alternator, otherwise one of the standard methods of starting S.C. motors must be employed. Since no switchgear is to be introduced between the two machines, the voltage across the terminals

of the motor must be reduced at starting in order to limit the current. The extent of this reduction will depend upon the size and design of the motor. For machines of less than, say, 25 b.h.p. about half the normal voltage is quite safe; for larger machines the reduction should be more. With the alternator running at its correct speed this reduction in voltage is quite easily accomplished by resistances in the field circuits of the exciter and of the alternator, so that there is no necessity for separate excitation. It is advisable, however, not to decrease the exciter voltage too much, otherwise it becomes unstable. The chief disadvantage of this method of starting up an induction motor is that on account of the large voltage variation necessary, the alternator cannot be used for supplying any other load. Also the resistance in the alternator field has to be greater than would normally be required.

As regards the variation of torque with speed, this relationship is rather complicated, since it depends upon a number of factors. Thus the torque exerted by an induction motor is proportional to the rotor current \times flux in air-gap $\times \cos \phi$, where ϕ is the angle of lag of the currents behind the e.m.f.'s of the rotor, and is given by $\cos \phi = \frac{R}{\sqrt{R^2 + (2\pi f L)^2}}$, where R is the rotor resistance and L the rotor inductance per phase and f = frequency of e.m.f.'s induced in rotor.

The flux in the air-gap is practically proportional to the stator terminal voltage, whilst the rotor current depends upon the load against which the motor has to start up, and upon the rate of acceleration. As regards $\cos \phi$, this quantity is small at starting, since the rotor frequency is then the same as that of the supply, $2\pi f / L$, being consequently large in comparison with the resistance of a S.C. rotor. As the motor speeds up, the rotor frequency decreases, until at full speed, $2\pi f / L$ is very small in comparison with R , and $\cos \phi$ is almost unity. It should now be evident that if the alternator voltage be varied in such a way as to maintain a constant current during the starting period, the torque exerted increases rapidly with the speed.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published August 26th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

12,814/14. Slip Rings. SIEMENS-SCHUCKERTWERKE. Slip rings for high-speed machines carrying heavy currents formed of metal strip placed on edge and wound into coils, with means for preventing radial displacement of the ends. (One figure.)

12,959/14. Gyrostatic Compasses. ANSCHUTZ & Co. The gyrostats are run in enclosed chambers containing a gas lighter than air to diminish windage loss without sacrificing the possibility of getting rid of heat by convection, as when a vacuum is used.

13,541/14. Incandescent Lamps. C. GLADITZ. A glower for incandescent lamps, consisting of a closely coiled tungsten wire coated with a paste of thorium and cerium oxides with a binder of sodium silicate in an inert gas. (Three figures.)

13,920/14. Searchlights. SIEMENS-SCHUCKERTWERKE. Searchlights particularly for following aircraft in which the barrel is arranged to rotate both on its vertical and horizontal axes, and the light aperture is situated in the normally upper part of the cylindrical wall of the barrel, and a plane inclined mirror, preferably of boro-silicate glass, is fixed in such a way as to face the ordinary curved reflector at the end of the barrel. (Six figures.)

14,378/14. Continuous-current Generation. SIEMENS BROS. DYN. WKS., LTD., and C. A. KOETTGEN. A system in which a turbine-driven asynchronous alternator has its stator windings connected to the slip rings of a rotary converter. During starting and bringing up to speed in step, an auxiliary low voltage source of continuous current is applied to the D.C. side of the converter.

14,381/14. Rendering Tungsten Ductile. C. TRENZEN. The powder is prevented from taking a crystalline form by treatment in a powdered state with alkaline nitrates with subsequent pressing and heating.

18,290/14. Writing Telegraphs. A. G. BLOXAM (*Telepantograph Ges.*) A telautograph or writing telegraph in which the position of the reproducing pen is controlled by the relative strength of currents in circuits in a moving coil system in a fixed magnetic field, and not by their absolute strength. (Three figures.)

18,566/14. Gas-filled Lamps. A. E. G. Metal filament lamps filled with a mixture of argon and a gas such as nitrogen indifferent chemically to the filament by which a less amount of blackening is obtained than with pure argon.

23,496/14. Rendering Tungsten Ductile. GLÜHFÄDENFABRIK AARAU A.G. A method of preparing non-crystalline tungsten, consisting in fusing the metal to a perfectly liquid state in a resistance furnace, and suddenly cooling with an air blast. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: MARKS (Aluminum Co. of America) [Composite conductor cables] 21,650/14; BURDON (Siemens-Schuckertwerke Ges.) [Insulators] 23,486/14; HELLMUND [Distribution] 2,432/15.

DYNAMOS, MOTORS AND TRANSFORMERS: BRITISH WESTINGHOUSE ELECT. AND MNF. CO. (Westinghouse Elec. & Mnf. Co., U.S.A. [A. C. Commutator motors] 8,672/15.

Electrometallurgy and Electrochemistry: FEENY (Fabrik Elektrischer Zünder) [Electroplating wire] 13,699/14; JOHNSON (Badische Anilin & Soda Fabrik) [Electrolytic production of alkali metals] 17,763/14.

Heating and Cooking: DEUTSCHE GASGLÜHLICHT A. G. (Auerges.) [Cooking apparatus] 7,964/15.

Ignition: CARPENTER [Gas-igniting apparatus] 18,504/14.

Incandescent Lamps: DEUTSCHE GASGLÜHLICHT A. G. (Auerges.) [Incandescent lamps] 19,729/14.

Switchgear, Fuses and Fittings: SIEMENS-SCHUCKERTWERKE Ges. [Protective gear] 16,860/14; ROCKSTROH [Control of printing machines, &c.] 17,602/14; SWYERS [Switches] 18,509/14; TUCKER & CRABTREE [Switches] 23,272/14; KLUIJTMANS [Fuses] 2,370/15.

Telephony and Telegraphy: DOOTSON [Mining telephones] 4,526/14; SIEMENS & HALSKA A. G. [Telephone installations in

which the subscribers' lines are grouped according to the frequency of the calls] 16,316/14; TELEPANTOGRAPH Ges. [Writing telegraphs] 17,755/14; GLEDALL [Telegraph testing switch] 20,556/14; NICHOLSON [Buzzers] 611/15; RAINES [Multiplex synchronising systems] 3,985/15.

Traction: COLLINS [Electrically controlled joints] 11,629/14 and [Electric railway systems] 11,630/14; BURDON (Siemens-Schuckertwerke) [Overhead conductors] 22,113/14.

Miscellaneous: SIEMENS-SCHUCKERTWERKE GES. [Electric winding and hauling machinery] 17,548/14; OLDHAM [Locking miners' lamps] 18,442/14; WILSON [Condensers] 19,506/14; DONATH [Discharging tubes] 20,374/14; GES. FÜR ELEKTRO-OSMOSE [Electrical separation of gelatine, &c.] 21,448/14; FINDLAY [Bullet localiser] 23,170/14.

The following Specification is open to Inspection at the Patent Office before Acceptance, but is not yet published for sale.

Miscellaneous: R. BOSCH [Band resistance for use with pedal switches] 11,480/15.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

17,860/01. Primers. SIR W. G. ARMSTRONG, WHITWORTH & Co., and G. STUART. Details of construction of an electric primer for explosives.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: COMPAGNIE FRANÇAISE DE L'AMIANTS DU CAP. [Cable insulation] 8,991/05; PORZELLAN FABRIK KAHLA FILIALE HERMSDORF KLOSTERLAUSNITZ [Insulator with rain cap] 10,972/07.

DYNAMOS, MOTORS AND TRANSFORMERS: B.T.-H. Co. (G. E. Co., U.S.A.) [Brush connections] 9,908/05.

Switchgear, Fuses and Fittings: A. H. MAYES and FERRANTI, LTD. [Motor starters] 10,719/07.

THE METROPOLITAN MUNITIONS COMMITTEE

SOME time ago it was announced that steps were being taken to organise the engineering facilities in London for the purpose of producing munitions of war. This task was entrusted to the Metropolitan Munitions Committee, and we learn that the organisation of that body is now practically complete, and that most excellent work is being done. A central office has been established at Alexandra House, Kingsway, with Mr. Cecil Partridge, late General Manager of the Central London Railway, as General Manager, and Mr. W. E. Ireland, Rolling Stock Superintendent to the L.C.C., as Chief Engineer. The jurisdiction of the Committee extends over the whole of the Metropolitan Police Area, which has been divided into ten districts, each under a District Manager, who is associated with an assistant and a Munitions Engineer. The following have been appointed District Managers:—

Northern.—A. Hugh Seabrook, Borough Electrical Engineer, Marylebone (acting) (62 Finsbury Pavement, E.C., temporary address).

North-Western.—E. T. Ruthven-Murray, North Metropolitan Electric Power Supply Co. (346 High Road, Kilburn, N.W.).

Southern.—A. C. Cramb, Borough Electrical Engineer, Croydon (Town Hall, Croydon).

South-Eastern.—W. G. Head (Borough Hall, Royal Hill, Greenwich, S.E.).

South-Western.—C. O. Grimshaw, Westminster Electric Supply Corporation (6 Eccleston Place, S.W.).

Eastern.—C. Newton Russell, Borough Electrical Engineer, Shoreditch (215-217 Bishopsgate, E.C.).

East Central and part South-Eastern.—E. Harlow, City of London Electric Lighting Co. (64 Bankside, S.E.).

Western.—R. S. Downe, Brompton & Kensington Electricity Supply Co. (Carnegie Library, Hammersmith, W.).

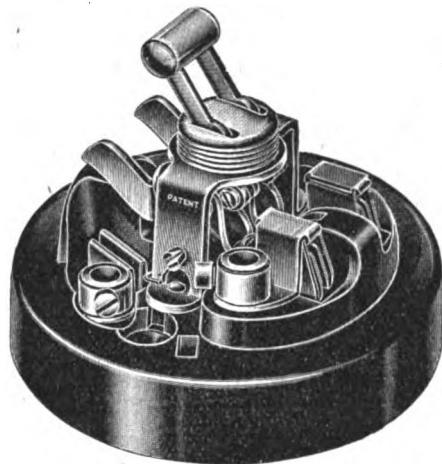

Poplar and Stepney.—G. M. Gill, Commercial Gas Co. (East London College, Mile End, E., temporary address).

Outer Eastern.—S. H. Wood, Gas Light & Coke Co. (Gas Works, Beckton).

Any information likely to be of use in connection with the production of munitions, and all inquiries, offers of premises, of tools, plant, or services, &c., should be directed to the General Manager, Metropolitan Munitions Committee, Alexandra House, Kingsway, or to one or other of the District Managers, according to the district.

SINGLE-TUMBLER DOUBLE-POLE SWITCHES

THE term single-tumbler double-pole switch is meant to convey that the article in question is a tumbler-action switch for double-pole connection. Thus instead of the usual coupling together of two separate single-way tumbler switches, we have the combination on one base of ordinary size. So far as we know, Messrs. A. P. Lundberg & Sons (477-489 Liverpool Road, London, N.) are the only manufacturers of switches of this kind; and their 10-amp. surface pattern is shown in the figure, the scale being two-thirds the actual size. A 5-amp. size is also made both for surface and

SINGLE-TUMBLER DOUBLE-POLE SWITCH.

flush work, and various patterns of cover (metal or porcelain) are available, the metal covers for surface work being generally lined inside with fibre. This type of switch is largely used on electric heating and cooking apparatus, in conjunction with some other type, for varying the number or arrangement of the heating sections in circuit. Some of these groupings are as follows:—Double-pole with series-parallel, double-pole with series-parallel and off, double-pole with "twinob," double-pole with "all-or-part," double-pole with special switch. Although the details of these controls are of especial interest to designers and makers of electric heating apparatus, who should write for the firm's special list "H," there are also uses to which these switches can be put in lighting installations. For example, when a lamp (or group of lamps) is on an out-of-doors circuit, or in a cellar or other more or less damp place, it is better to break the circuit on both poles than to use a single-way switch. The same arguments apply also to the control of plug-sockets, an additional one being that there is no chance of shock at all if the socket is entirely "dead" when off. It should be obvious that these compact forms of double-pole switch are also useful in laboratory, lecture, and testing work; and on various classes of practical apparatus in wide use.

SILK SHADES

THE season is fast approaching when the public will be looking to their lighting arrangements, more especially regarding lamps and shades. For some little while the Edison & Swan United Electric Light Co., Ltd. (Ponders End), have been doing a business in their silk shade department, but

this is the first opportunity we have had of calling special attention to this branch of the firm's manufactures. A neat little stiff-covered booklet of silks has been forwarded to us, which contains nearly fifty different tints of reds, greens, blues, browns, &c., with a large sample attached to enable a

prospective buyer to test the quality. All shades can be recovered in a similar fashion to match others, and old pattern shades can be renovated. The illustration here represents one of the many stock patterns, but it is also a speciality of this department to make for all individual requirements.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Armagh.—An electric lighting scheme is under consideration.

Haslingden.—The Co-operative Society propose to put down an electric lighting plant.

New Zealand.—An electric lighting scheme is to be put in hand at Bay Town, a suburb of Dunedin.

St. Helens.—An L.G.B. inquiry was held last week concerning a loan of £15,000 for new plant, &c. The Borough Electrical Engineer informed the Inspector that these extensions would have been necessary apart from the war, but the great demands of firms engaged upon munitions rendered them more necessary now. There was no opposition. The proposed extensions include a condenser (£9,985); switchgear (£515); cooling tower, pipework, &c. (£1,250); water-tube boiler and mechanical stokers (£1,750).

Wiring

Batley.—Electric lighting of Methodist Chapel. Tenders to W. Purdy, 59 Canary Islands, Batley Carr, Batley, by Sept. 6th.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Birmingham.—Enlargement of East Telephone Exchange. H.M. Office of Works, Storey's Gate, London.

Briton Ferry.—Alterations and additions at Council School. Clerk, County Hall, Cardiff.

Chorley.—Extensions to Leyland Motors, Ltd., factory.

Jarrow.—New goods warehouse, &c., for North Eastern Railway Co. Architect, Arthur Pollard, Irving House, Westgate Road, Newcastle-on-Tyne.

Neath.—Joint Isolation Hospital. Architect, J. Cook Rees, Parade Chambers.

Miscellaneous

Australia.—The Deputy Postmaster-General, Melbourne, requires a large quantity of various telephone parts. Sept. 21st.—The Deputy Postmaster-General, Brisbane, requires 2,860 yds. of silk- and cotton-insulated switchboard cable. Oct. 6th.—The Deputy Postmaster-General, Adelaide, requires a portable direct-coupled internal combustion engine and dynamo. Oct. 6th. Copies of specifications, &c., may be consulted at 73 Basinghall Street, E.C.

London: Islington.—The Guardians require a six months' supply of electrical fittings and sundries. Clerk, St. John's Road, Upper Holloway. Sept. 9th.

South Africa.—The Johannesburg Council requires 1,595 meters and 50 time-switches. Copy of specification may be seen at 73 Basinghall Street, E.C. Sept. 25th.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Coatbridge.—A contract has been placed with Messrs. Chamberlain & Hookham for a twelvemonths' supply of meters.

Coventry.—We mentioned a short time ago that the Electricity Committee had recommended a large scheme of extensions rendered necessary by demands from factories employed on Government contracts, on condition that certain guarantees were forthcoming from the Minister of Munitions which would safeguard the Corporation against loss on capital account in the event of a cessation of the additional demand for power. It is now stated that sufficient assurances have been given, and application is to be made for the necessary loan amounting to £80,088 10s. Meanwhile, provisional contracts

have been entered into with the British Thomson-Houston Co. for a 6,000-kw. turbo-alternator, and with Babcock & Wilcox, Ltd., for four boilers. To make room for this new set, two 800-kw. sets will be displaced.

APPOINTMENTS AND PERSONAL NOTES

We are pleased to record that the Managing Director of our contemporary, the *Electrical Times*, Mr. R. W. Hughman, has been promoted to a Captaincy in the 2nd Battalion of the 9th Middlesex (Territorial) Regiment. Captain Hughman joined the regiment as 2nd Lieutenant soon after the commencement of the war.

The Bradford Electricity Department requires switchboard attendants. Wages 40s. per week.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £84 to £85 (last week £76 10s. to £77 10s.).

Liquidation.—The adjourned meeting of creditors of Vanners Electrical Cooking & Heating Appliances, Ltd., will be held at Blomfield House, 85 London Wall, London, E.C., on Thursday, September 9th, 1915, at 12.30 p.m.

LOCAL NOTES

Aberdeen: *Reduced Street Lighting.*—The enormous reductions in street lighting due to the war have resulted in an annual saving of £5,352, apart from globes, carbons, &c.

Belfast: *Fire at Electricity Works.*—We are now able to give a little more information with regard to the rather serious fire which occurred at the electricity works on the 22nd inst., to which we briefly referred in our last issue. As we stated last week, the fire involved the part of the building immediately over the bunkers. This portion of the building was designed to avoid coal dust causing a nuisance in the adjoining street, and was, in consequence, poorly ventilated, and was constructed largely of wood. Heating in one of the bunkers liberated sufficient gas to fill this structure; the gas became ignited, and fired all the woodwork simultaneously. The damage is chiefly confined to this structure and the coal conveyor, which is partly destroyed. There was no interruption to the electricity supply whatever, the fire brigade effecting a splendid save of the adjoining buildings. The whole is covered by insurance, and the work of restoration will easily be completed before the winter's load.

Bridlington: *Electricity Works and Lighting Regulations.*—Councillor J. V. Mainprize, a former Chairman of the Electricity Committee, has been instrumental as a Special Constable in getting the Acting Borough Electrical Engineer fined for failing to obscure the roof lights at the electricity works.

Brighton: *Street Lighting Restrictions.*—The Electricity Committee has arranged to reduce the expenditure on street lighting during the coming year by a further £5,000, and this, added to the present reduced street lighting, involves a loss of revenue to the electricity undertaking to the extent of £9,000 per annum.

Glasgow: *Fire.*—There was a fire on the premises of the well-known Glasgow firm of electrical engineers and contractors, Messrs. M'Whirter & Son, on Friday, which resulted in some £1,500 damage to the stock.

Halifax: *Electricity Accounts.*—After meeting capital

charges, there was a nett profit of £13,036 on the working of the electricity undertaking for the year to March 31st, compared with £10,268 in the previous twelve months. Of this balance £4,041 is transferred to relief of rates, £2,500 is absorbed in a third instalment of the cost of the foundations for the 3,500-kw. turbo-alternator, and, after meeting the cost of a number of other items of a capital nature, there is a balance of £4,304 to be carried forward, compared with £585 in the previous year. The amount transferred to relief of rates is slightly in excess of that similarly transferred in 1913-14. The total number of units sold was 11,075,893, against 9,670,008 on March 31st, 1914.

London: *Stepney: Coal Delivery.*—Arrangements are being made for the acquisition of a sufficient river frontage to enable coaling steamers to be brought alongside the electricity works.

Salford: *New Tariff.*—The Electricity Committee has decided that electricity used for motors driving dynamos for the purpose of producing energy for lighting will be charged at lighting rates except in the case of motor-generators used for cinematographs, when the charge will be a flat rate of 2½d. per unit.

Yorkshire: Power Co. and Small Districts.—Apparently, as the result of the attitude of the Board of Trade during the progress of its Bill in Parliament last year, the Yorkshire Electric Power Co. is now approaching a number of the smaller districts in its area with a view to applying for electric lighting provisional orders. In the company's Bill last year it was proposed to take lighting powers *en bloc* for practically all districts in the company's area in which provisional orders had not been granted, but the Bill was rejected after evidence had been heard from the Board of Trade to the effect that objection was taken to this method of procedure, and that the right course was that the company or the local authorities should apply for separate electric lighting orders.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

South Metropolitan Electric Light and Power Co.—Dividends on the 7 per cent. cumulative first preference shares and 6 per cent. cumulative second preference shares are announced.

NEW COMPANIES

ANDOVER & DISTRICT ELECTRICITY CO., 26 Bridge Street, Andover. Capital £10,000. To take over from Messrs. Crompton & Co. the Andover Electric Lighting Order, 1915.

Installation Estimates.—We have received a copy of a Paper which was read some little while ago before a students' meeting of the Glasgow Local Section of the Institution of Electrical Engineers by Mr. N. C. Woodfin, which was entitled "Electrical Estimates and Opportunities." The author enlarged upon the trouble and expense that contractors are put to in preparing competitive estimates for installations sometimes of considerable complexity, especially when no specification by a consulting engineer is issued and the information given by the purchaser is of a meagre character. His remarks were aptly illustrated by an example worked out in detail of a power installation in a mill, for which his firm finally lost the order because a cheaper form of generating plant than they considered suitable was accepted. Other cases were quoted to show that the cost of estimating often swallowed up the slender margin of profit which was all that orders could be obtained on in these days of severe competition. He pointed out how the electrical industry was penalised by the system of free estimates, and urged that they should be paid for if firms with anything short of an enormous turnover were to make a living profit. His object in bringing the matter forward was to urge that the Institution of Electrical Engineers should take some action to better the state of affairs.

The Iron and Steel Institute.—The programme of the autumn meeting in London, Sept. 23rd and 24th (at the Institution of Civil Engineers, Great George Street, Westminster), has now been issued. Among the Papers down for reading is one by Prof. K. Honda and H. Takagi on the magnetic transformation of cementite.

Wireless Control of Torpedoes.—The *Electrical World* (New York) states that the United States Navy contemplates the building of special hydro-aeroplanes, fitted with wireless apparatus by which torpedoes in the water below can be steered and controlled.

SUMMARY

THE position of electrical manufacturers whose active munitions output places them in a position of having to neglect the manufacture of electrical plant is referred to in an article on p. 370.

THE meeting of the British Association at Manchester commenced on Tuesday with the reading of the Presidential Address, and the addresses of the presidents of the sections were given yesterday (p. 370).

MR. S. W. CUTTRISS gives a series of useful curves for determining the number, spacing, and size of incandescent lamps required to give any desired degree of illumination with different types of reflectors (p. 371).

THE appearance of patent specifications of German origin among those published every week at the Patent Office is explained (p. 372).

THE construction of small motors to run off either D.C. or A.C. circuits is discussed in our Questions and Answers columns (p. 372).

A CORRESPONDENT deals with the position of the electric lamp industry in Spain (p. 373).

SOME misunderstanding has arisen regarding the Arbitrator's award as to London wiremen's wages owing to a circular letter from the wiremen's union which was referred to in some of our contemporaries (p. 373).

A DESIGN of conduit continuity grip is illustrated (p. 373).

AMONG the subjects of specifications published by

the Patent Office last Thursday are: finding the position of ships at sea by combined acoustic and wireless signals, protective systems, cables, and telephonic bullet localisers. The A.E.G. patent for long-necked bulbs with baffle plates in half-watt lamps is also published. One or two amendments of electrical patents have been allowed, and B.T.-H. patents for circuit-breakers and train-control expire this week after a full life of fourteen years (p. 374).

EXTENSIONS are to be carried out at Bury (£7,225); the Amble Council proposes to adopt street electric lighting; the Johannesburg Council requires a large number of house-service cut-outs; electrically-driven letter-sealing machines are required in New Zealand; and stores are required in various places (p. 375).

THERE seems every prospect that the proposed linking-up scheme between Battersea, Fulham, and Hammersmith will now proceed without Hammersmith taking part in it.—The suggestion of Councillor Ross Clyne for the appointment of a Special Committee to inquire into the working and control of the Manchester Electricity Department met with no support when it came before the Corporation last week (p. 376).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING SEPTEMBER 18TH, 1915,
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Monday: Section I., technical instruction. Section III., musketry at range. Sections II. and IV., squad drill or signalling.

Tuesday: Section II., technical instruction. Section IV., musketry at range. Sections I. and III., squad drill or signalling.

Classes for signalling instruction are being formed, and the names of those desiring to take part should be handed to the Section Commanders.

The Corps will still be glad to welcome recruits. Although primarily appealing to members of the engineering institutions, others whose tastes lie in the direction of a technical training will find this Corps meet their views.

Applications should be made to Lt.-Col. C. B. Clay, V.D., the Commandant of the Corps, at Marconi House, Strand, W.C.

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

The Munitions Inventions Branch.—The Munitions Inventions Branch which, as we pointed out on page 350 of our issue for August 19th, has been constituted by the Minister of Munitions, has removed from Armament Buildings, Whitehall Place, S.W., to larger accommodation in Prince's Street, Storey's Gate, S.W. The panel of honorary scientific and other experts, whose names we have already given, is now at work in committees, and is already dealing with a large number of proposals.

OUR CHANGED ELECTRICAL INDUSTRY

A NYBODY who might have proclaimed, at the outbreak of the war thirteen months ago, that the majority of our large electrical manufacturers and a continuously increasing number of smaller ones would soon be chiefly engaged making non-electrical material would have been greeted with a smile of contemptuous incredulity. Yet such has been the case for a considerable number of months. For obvious reasons we can publish no quantitative information as to output of war munitions from electrical manufacturing works, but we are betraying no secrets in stating that in view of the necessity for rapid output, the manufacture of electrical machinery and apparatus has to take quite a secondary place in many large works, which, previously to the war, never contemplated making other things than electrical plant. Not only has the "business as usual" policy been absolutely abandoned—if, indeed, it ever came into effect—but the desirable attack on the world's markets to secure Germany's colossal export trade has necessarily to be deferred during the present time, until, at any rate, the need for ammunition is officially stated to be less great. That the time has not come for any diminution of the present rate of production of war material should be fairly obvious. The slow progress in the western theatre of the war, the abandonment of Warsaw and the hundreds of square miles of their own territory which the Russians have had to relinquish temporarily to the enemy, and finally the enormous expenditure of high explosive shells in the Dardanelles, all point in one direction: more rapid production of ammunition is necessary. It has become a habit to accuse the Government of reticence as to the true state of affairs, but in this thing there has been no reticence. More munitions have been called for from the works already manufacturing them; the output has been increased, and still more is needed. More workmen have been required; they have been forthcoming, and still more are needed. More factories have been wanted to manufacture munitions; hundreds have been converted to munition factories, and still more are needed. In this state of affairs, it is greatly to be regretted that, in some quarters, the suggestion has been made or hinted that the patriotic works who have neglected their normal electrical output to fulfil the country's urgent call should now consider whether they have done right, and the bait of increasing oversea trade is held up to them. It is but too true that trade will be lost, and that neutral countries will benefit in the meantime, but this cannot be otherwise. So far the electrical manufacturers as a whole have not been out of pocket by the war, but even if they had been, their duty to the country comes first.

THE BRITISH ASSOCIATION AT MANCHESTER

I N spite of the war the meeting of the British Association is being held at Manchester, although it is of strictly businesslike character and is shorn of the social features which have characterised previous gatherings. The shadow of the war, however, distinctly lies over the meeting, although necessarily not many of the papers to be read deal directly with war subjects, except in the Economic Science Section. The proceedings commenced on Tuesday night with the reading of Prof. A. Schuster's Presidential Address to the whole Association, on the common aims of Science and Humanity, containing a brave attempt to lift our thoughts for a moment from the gross materialism of war. The addresses of the presidents of the different sections followed yesterday, and to-day the reading and discussion of papers is in full swing.

Dr. H. S. Hele Shaw's presidential address to Section G (Engineering) was essentially a militant address, and emphasised the part played by men of science in modern warfare. He dealt particularly with the ways in which the Section can bear a share of the burden. He suggested that the three existing research committees should be continued, but a further special committee formed first to undertake any work which

might be of use in an advisory capacity or by research, or, indeed, in any other way for direct assistance in the war, and secondly to deal with the situation that will arise after the war in helping to make ready for the struggle that Germany is certain to put up in the arts and manufactures. In this latter connection he put forward statistical evidence of the rapid and increasing rate of increase of Germany's iron and steel industries during the past 50 years, which he compared with the slower rise of our own. The latter part of the address studied in some detail the causes of the greatness of this advance. It was, he said, in the matter of scientific organisation even more than the organisation of science that Germany had achieved such wonderful results, and it was in this direction that we must leave no stone unturned if we wished to have any chance of holding our own in the future. The fields to which he gave particular attention were technical education, where much had been commenced but much remained to be done, and research, which was another subject wherein a British Association committee might render great service. Another equally important field was standardisation, and in this connection he referred to the important work of the Engineering Standards Committee, and incidentally quoted a remark of the Secretary of the International Electrotechnical Commission to the effect that the want of uniformity in the rating and testing of electrical machinery had been a serious evil. The German standardisation rules, for instance, which, through well-organised and combined effort on the part of the German makers, had previous to the war become widely recognised on the Continent of Europe as well as in many countries to which British machinery is exported, by permitting a higher temperature rise than is considered good technical practice in Great Britain, certainly had not assisted the British maker in foreign markets. He also urged that such a committee that he was proposing could exert influence regarding the holding of exhibitions and the establishment of commercial museums and the reform of patent law. The most important work, however, was the organisation and co-ordination of industry, without which efficiency could not be obtained. The British Association was a powerful body, and would be listened to if such work was carefully and energetically done.

As regards the papers and reports, the interest of electrical engineers centres mainly around the Engineering Section, where Prof. Miles Walker will read practical papers on the eddy-current losses in the end plates of large turbo-generators and on commutation, and a theoretical paper on the possible existence of mutual induction between masses. The heating of iron by high frequency magnetisation will be dealt with by Mr. N. W. McLachlan, and Messrs. H. M. Lacey and C. H. Stubbings will also read a paper on transformer core losses as affected by triple harmonics. The wireless telegraph papers will include one by Dr. Eccles and Mr. A. J. Makower on oscillations in coupled circuits, two by Prof. G. W. O. Howe on the capacity of aerials, and a note on earth resistance by Prof. E. W. Marchant. The report of the Committee on Wireless Telegraph Research will, however, be submitted to Section A. Although not mentioned in the preliminary programme, there is a likelihood of an interesting discussion on municipal engineering (including electricity supply) being held at one of the meetings of Section G.

Enemy Shares in Electrical Co.—The Concordia Electric Wire Co., Ltd., which was registered in 1902 as an English branch of a firm of electrical cable and wire makers at Adlershof, near Berlin, was summoned at Bow Street Police Court last week through two of its directors, Robert Fifer and Leopold Aron, for not communicating to the Public Trustee full particulars of 13,993 shares in the company. According to counsel who prosecuted on behalf of the Director of Public Prosecutions, the original nominal capital of the company was £2,000 in £1 shares, all but seven of which were held by Aron on behalf of the German company. In November, 1913, a further 12,000 £1 shares were issued in a similar way. In May, 1915, it was stated, Aron, fearing internment, which has since happened, transferred the whole of the shares to two of the company's employees under an arrangement by which he would receive all the profits, but his name disappeared from the register of shareholders. No notice of this transaction was given to the Public Trustee. For the defendants it was stated that the omission was due to ignorance, and that no part of the profits of the company had been transmitted to Germany since the war began. The magistrate, however, took a serious view of the case, and fined the defendants in all £750 and 25 guineas costs.

Electric Commercial Vehicles.—Some trials of heavy electric vehicles conducted by the Zurich electric supply authorities resulted in a journey of 120 kw. (74·5 miles) in 6½ hours (*i.e.* an average of 11·5 m.p.h.), with a useful load of 1,500 kg. (1½ tons) over a rather hilly route with a total rise of 670 metres (220 ft.). The result is of particular interest to the Swiss on account of the serious shortage of petrol with which they are faced.

INSTALLATION CURVES FOR INCANDESCENT LAMPS AND SHADES

By S. W. Cuttriss

IN the early days of the electric light industry, when it was desired to lay out an installation of incandescent lamps, the contractor either proceeded by guesswork or adopted the rough approximation of one 16-c.p. lamp per 64 sq. ft. of floor area. If the resulting illumination was not equal to requirements, or if the lighting proved excessive, the lamps were changed for others of higher or lower candle-power as desired. Foot-candles, lumens, and such-like terms, more or less familiar to the modern engineer, were then unknown, and the possibility of calculating beforehand the intensity of illumination to be anticipated from a given lay-out was a proposition undreamt of. Neither did he trouble his head with considerations of the influence of reflection and diffusion from surrounding surfaces or the probable effect of different designs of shades on the distribution of the light.

Fortunately the study of scientific illumination has progressed side by side with improvements in the efficiency of

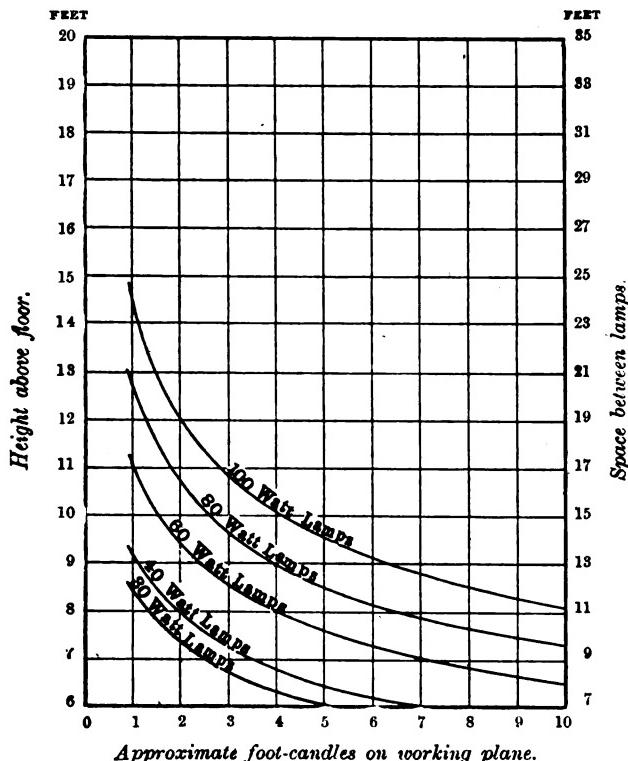

FIG. 1.—“EXTENSIVE” TYPE SHADES.
For use in small rooms, or large rooms with low ceilings.

the incandescent lamp, and one is now able to calculate with fair accuracy the requirements necessary to produce with economy any desired lighting effect or definite intensity of illumination; therefore if a little patience is exercised to make the necessary calculations, any installation can be figured on paper with reasonable confidence that the result will be satisfactory. Unfortunately, if due consideration is given to all the varying factors, the calculations become somewhat tedious and the keenness of competition discourages any attempt to devote the necessary time to a careful consideration of the work on scientific lines. After filling a few sheets of foolscap with figures involving many plus and minus factors the contractor is apt to get disgusted, throw the lot into the waste-paper basket, and trust as formerly to his empirical rules, if he has any. A sympathetic feeling for the difficulties of the position caused the writer to see if the numerous and conflicting data could not be boiled down and a series of curves obtained which would be sufficiently accurate for average conditions, and at the same time ensure a reasonable confidence in the illuminating effect resulting from their application.

The introduction of the metallic filament lamp necessitated the design of special types of reflectors for the double purpose of shielding the eyes from the highly incandescent filament and also for deflecting downwards the horizontal rays which form the major portion of the light radiated by the lamps.

Manufacturers have evolved several standard designs, varying in their power of concentrating the light in a contracted area underneath the lamps, according to the purpose for which

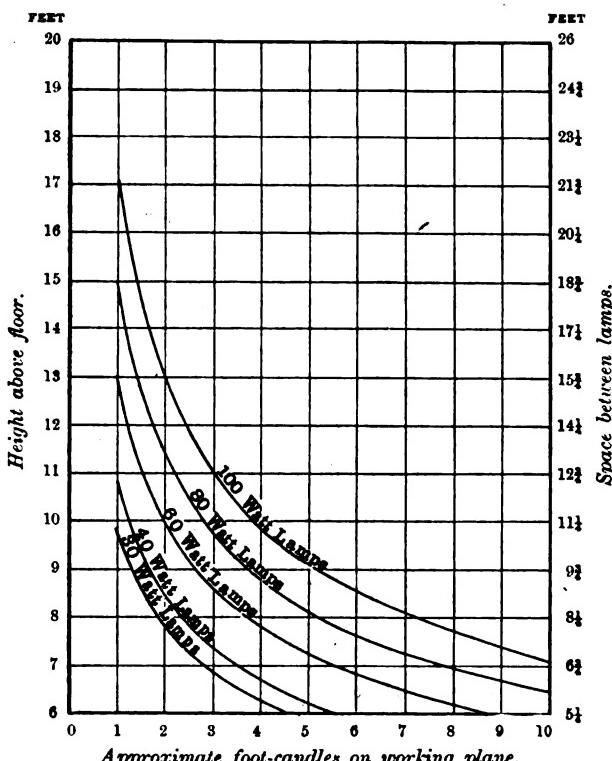

FIG. 2.—“INTENSIVE” TYPE SHADES.
For use in large rooms with average ceiling height, and small but lofty rooms.

they are required. Three types specially useful for general installation work are known as “extensive,” “intensive,” and “focussing” patterns, and they are designed to give a fairly even illumination on a horizontal plane under the

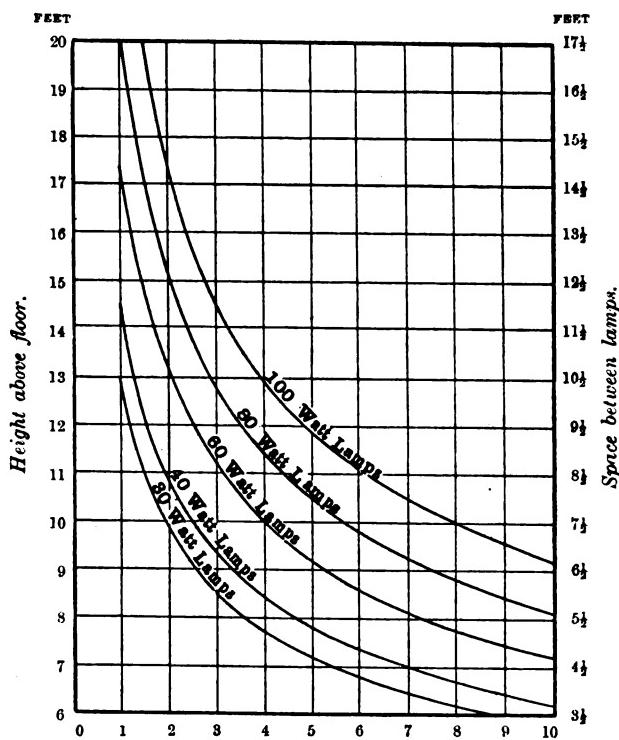

FIG. 3.—“FOCUSING” TYPE SHADES.
For use in large rooms with high ceilings.

lamps enclosed by angles from 45° to 15° from the normal. To obtain even illumination over an extended area it is necessary that the units be spaced apart a definite distance, relative to their height above the working plane, which

latter is generally accepted as $2\frac{1}{2}$ ft. above the floor. The spacing distances vary for each type of reflector.

Although many of the modern shades are very efficient in their reflective power, there is necessarily a certain loss of light due to absorption by the material of the reflector, and this has to be allowed for. Further, the reflection from the walls and ceiling of a room have to be taken into consideration, which latter may have a very appreciable effect on the resulting illumination on the horizontal plane.

The curves reproduced in Figs. 1, 2, and 3 have been calculated for average conditions in rooms with light-coloured walls and white ceilings, using the present standard lamps of from 30 to 100 watts, having an efficiency of 1.3 watts per c.p. (British). Although the curves are drawn for illumination on the working plane, the height of the lamps from the floor level is stated, which latter is the figure of practical use when installing. The foot-candle intensities are only approximations, and photometric tests might very possibly show somewhat different values, but this fact does not destroy the utility of the curves, which will be found to afford a ready means of comparing one type of reflector with another under varying conditions, without having to wade through tables and manufacturers' catalogues, and in the end probably wasting valuable time without any satisfactory result.

Comparing the "extensive" type curves, it will be seen that 30-watt lamps at a height of $8\frac{1}{2}$ ft. from the floor and spaced 12 ft. apart will give 1 f.c. on the working plane, while 100-watt lamps at $14\frac{1}{2}$ ft. and spaced 24 ft. will give the same illumination, or the latter lamps at $8\frac{1}{2}$ ft. and spaced 12 ft. will give 8 f.c. With focussing shades and 30-watt lamps $8\frac{1}{2}$ ft. high, it will be necessary to space them 6 ft. to obtain even illumination, and the intensity will then be 3 f.c. on the working plane, whilst 100-watt lamps at $14\frac{1}{2}$ ft. and spaced 12 ft. will also give 3 f.c. It is evident these curves will enable the contractor to choose readily, without elaborate calculations, the most suitable type of shade and lamps, and ascertain the height and spacing necessary to obtain any desired intensity of illumination on the working plane.

GERMAN PATENTS AND THE WAR

IT will have been noticed by readers of our Patent Record that the batch of specifications published by the Patent Office each week still contains a considerable number of German origin, some even dealing with war material. It is perhaps not generally realised, however, that the majority of these relate to applications made during the earlier months of 1914, and in many cases the date applied for under the Convention is much earlier. An example of this is the German anti-aircraft searchlight patent (18,920/14) abstracted in our Patent Record last week, the date of application in this country being June 9th, 1914, and the Convention date June 21st, 1913. This was not, as might have been thought, a case of the Germans endeavouring to teach us how to repel their own aerial attacks. An easy way of ascertaining whether an application was made before or after the declaration of war is to see whether the number is earlier or later than 18,250/14, which was the number of the first specification with a date subsequent to August 4th, 1914. German and Austrian applications are still being received under the new procedure, although no patents are to be granted on them during the war, but it is noticeable that the number of specifications of German origin published bearing numbers higher than the above is small. Thus in the list of specifications published to-day, out of the twenty-one (including all subjects) before 18,250/14, over half are, so far as can be judged, of German origin, while among the remaining sixty of later date only eight names apparently of German applicants appear, and in nearly all cases the Convention date is before August 4th, 1914. Again, in the list of applications published in last week's official journal, only one or two German names can be found in the whole 318, although there are quite a number from allied or neutral countries. Incidentally, it may be mentioned that of all these applications forty-three, or 18.7 per cent., relate directly to war material. Renewal fees appear to continue to be paid on German-owned patents to a certain extent, but, as far as we can see, the proportion of German names among the list of patents void through non-payment of renewal fees is larger than usual.

Royal Engineers (Wireless Section).—There are several commissions available in the Wireless Section of the Royal Engineers for general service during the period of the war. Applications are invited from candidates with good technical knowledge of wireless telegraphy and used to the control of men. Applications should be addressed to Major Handley, O.C., Wireless Training, Oxford Cottage, Sandown, I.W.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,459.

Large motors of the self-starting synchronous type are not generally suitable for starting against any considerable torque, owing to the high starting current. It is, however, possible to improve the starting conditions by using an induction motor rotor as the field and inserting resistance across the slip-rings. A disadvantage of this arrangement is that the voltage induced across the slip-rings at starting may be 1,000 or 1,500 volts, which requires special precautions in the way of insulation, &c. Is there any simple method of overcoming this trouble? Several self-starting machines have been built recently with their exciters series wound. Have series-wound exciters any particular advantage over the more usual shunt-wound exciters?—J. I. E.

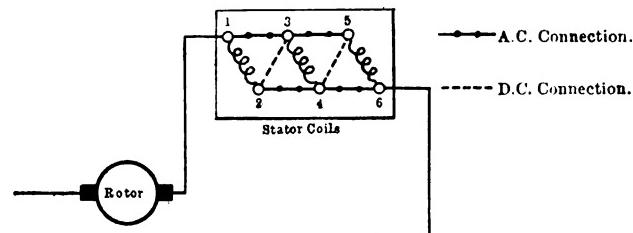

(Replies must be received not later than first post, Thursday, Sept. 16th.)

ANSWERS TO No. 1,457.

I HAVE an electric drill, $\frac{1}{4}$ in. capacity, 110 volts, single-phase, squirrel cage rotor, and wish to run this off either A.C. or D.C., same voltage. The rotor has been wound and fitted with a commutator, and the machine runs fairly well as a repulsion motor, but does not develop full torque. As a series D.C. machine it gets excessively hot, after a few minutes' run; have tried various means of keeping cool, such as fans, &c., but without success. Are there any means I can adopt to enable this machine to be run satisfactorily as a repulsion or series machine on A.C. or series, or shunt on D.C. The frequency of A.C. supply is 60.—W. E. L. (Canada).

The first award (10s.) is made to "H. J. E." for the following reply:—

In order to simplify the connections, it will be advisable to re-design the machine to work as a series motor on either A.C. or D.C. When running as a series motor on D.C. the back e.m.f. of the armature is equal to the applied pressure minus the drop in the field and across the brushes. Whereas with a series connection on A.C. the back e.m.f. of the armature is equal to

the vectorial difference between the applied pressure and the transformer voltage of the stator winding. This latter voltage will most probably be as much as $0.6 \times$ applied pressure, so that the voltage on the armature is far larger on D.C. Also the current taken by the motor for the same horse-power at the same speed is higher on A.C. on account of the power factor being less than unity in addition to the lower efficiency. Consequently, not only is a stronger flux per pole required on

D.C. due to the higher volts on the armature, but also more turns per pole are needed on account of the reduced current. By working out the saturation curve of the machine it would be found that approximately three times as many turns are required per pole on the stator for the same voltage on D.C. Moreover, this is corroborated by experiment. Therefore the stator should be stripped and re-wound with $0.67 \times$ existing turns per pole, using three wires in parallel, the combined section being equivalent to the section of the stripped wire. Then if all six ends of the stator winding are brought out to a terminal board on the carcase, as shown in the accompanying sketch, it is quite a simple matter to place links across terminals 2 and 3, 4 and 5 for the D.C. circuit, and across terminals 1, 3, and 5, 2, 4, and 6 for the A.C. circuit. Incidentally, if the armature has a two-pole winding, or a four-pole wave winding, the wire should have one half the section of the stator copper, and the turns in series between the brushes should equal the stator turns in series, with the A.C. connection. In this manner the same horse-power will be obtained at the same speed on 110 volts, 60 cycles as on 110 v. D.C.

The second award (5s.) is given to "BELFAST," who writes as follows :—

In a D.C. motor the applied voltage has only to supply the voltage drop due to the resistance of the windings, and to neutralise the back e.m.f. But in an A.C. motor the terminal voltage has also to supply the voltage drop due to the inductance of the windings; and in a small motor this drop is a considerable fraction of the total voltage. It is therefore evident that for the same terminal voltage a greater portion of it is available for the production of mechanical power in the case of a D.C. than in that of an A.C. motor. This explains why the machine in question, when running off A.C., cannot be expected to develop full torque. The latter can only be varied by altering the position of the brushes, unless the machine is re-wound. It is impossible to say whether the torque could even then be improved without knowing the particulars of the present windings. The best thing is for "W. E. L." to experiment with the brush position, and also to try running the machine as a series A.C. motor. The latter would be a much more convenient method, since no alteration in the connections would be required when changing over from A.C. to D.C., or vice versa.

With regard to the overheating experienced when running off D.C., this trouble is due to the fact already mentioned, namely, that a motor is capable of a much greater output off D.C. than off A.C., the supply voltages being equal. Fans, &c., fitted on small motors produce very little effect, and the only remedy is to reduce the speed, either by re-winding the armature or by inserting resistance in series. Re-winding with a larger number of conductors would leave its characteristics as a repulsion motor practically unaltered, but as a series A.C. motor it would exert less torque than at present. The employment of a series resistance entails the waste of a certain amount of power in it, but that is generally of secondary consideration in the case of very small motors. The disadvantages of a shunt arrangement for such a machine outweigh its advantages.

Question No. 1,456.—It has been pointed out by a correspondent that the three curves given in the first reply to this question, published on p. 365 of our issue of Sept. 2nd, are not strictly accurate, in that they show zero torque at zero speed, which could not be the case, or the motor would not start. The fact is, of course, that a stator current, however small, produces a torque, and the motor starts rotating when this torque just exceeds that due to friction. We reproduced the curves exactly as drawn by "W. H." and regarded them only as very rough approximations to show the general character of the action.

CORRESPONDENCE

ELECTRICAL TRADE AFTER THE WAR.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—It may be interesting for your readers to be impressed with a few facts which are just brought to my attention. Although they apply to the Spanish market, their general consequences will bear also on all neutral markets and indirectly on the Allied markets.

The position of the electric lamp industry in Spain was, up to a few weeks ago, almost the following : Spanish industry produces Spanish-made lamps at cheap prices, yet there was an opening for foreign industry in spite of the heavy import duties in Spain. Since the entry of Italy into the war, German lamps were almost entirely prevented from entering Spain. Now, however, I have definite information that German well-known brands are again entering in Spain from Switzerland, where factories have been started under Swiss names and whose products are allowed to pass through France as being Swiss goods. In such a way those so-called Swiss lamps are offered approximately 30 per cent. cheaper than any other lamps from the Allied countries.

It is urgent that the attention of the French Government

should be drawn to the fact that some Swiss products are not purely Swiss, but conceal German origin. If we fail to stop this kind of competition during the war, what will happen after the war, when apparently all German goods will be naturalised Swiss or Dutch? This question is of the highest importance, and steps should be taken in France to examine the position. Incidentally, I wish to point out that the very low quotations adopted now by German manufacturers in the lamp business for their export goods show that, as has been told in different quarters, the German industry is working heavily on stock and making ready to overflow all neutral markets and thence our own countries after the war if we do not stop the leakage effectively, not merely with certificates of origin, but by an absolute control of the producing industries and their ultimate destination. We would be really too simple if, after the terrible strain put on all the Allied countries, we should not be intelligent enough to reap also the benefits of our sacrifices.

Yours faithfully,

R. STEYLAERS.

Anglo-Continental Sales Co.,
7 Idol Lane, E.C., Sept. 2nd, 1915.

THE INCREASE IN LONDON WIREMEN'S WAGES.

To the Editor of ELECTRICAL ENGINEERING.

September 1st, 1915.

SIR,—The District Secretary of the London District Electrical Trades Union has circularised the Electrical Press, stating that Sir David Harrel, the Arbitrator, has awarded their members an advance of 1d. per hour, which, coupled with the penny advance obtained by the Union last year, constitutes an increase of 1½d. per hour, in a little over fifteen months, for electrical wiremen and fitters in the Metropolitan district.

This statement is extremely misleading and avoids the main facts, the intention being, no doubt, to claim a series of victories over the employers, who, however, stand in the happy position of knowing that the penny advance was offered by the Masters, and accepted by the Union after the strike, which from the men's point of view was not a brilliant achievement. In addition to this, an advance of 1½d. per hour was demanded by the men and refused. However, the Masters agreed to arbitration, realising that an increase of wages was justified during the present national crisis, with the result that the Arbitrator awarded half the amount demanded.

Although this award applies only to members of the London Union and, strictly speaking, is limited to such, the members of the London Electrical Masters Association have decided to apply the increase to all employees, *Union and non-Union*, although no agitation has been apparent among their non-Union employees.

Yours, etc.,
W. ELLERD-STYLES.

[ELECTRICAL ENGINEERING published the Arbitrator's award in full on August 19th (p. 351), and did not publish the statement referred to by Mr. Ellerd-Styles as misleading in the first part of his letter.—ED., E.E.]

THE HEMMING CONDUIT GRIP

THE latest form of the Hemming conduit grip is slightly different from the original design, which was described in ELECTRICAL ENGINEERING, June 18th, 1914 (p. 381). In the present pattern illustrated here, a pin recessed to fit the curve of the bore of the socket passes through the boss in a direction tangential to the tube, and carries a series of teeth, which, on the tightening of the nut which draws up the pin, locks the tube and at the same time makes excellent metallic contact

HEMMING PATENT CONDUIT GRIP.

through the enamel. It can be used with any class of tube, close joint or seamless, and locks firmly even if the tube is slightly under diameter. Only the screwing up of the nut is required to establish continuity, and the tube can be released when necessary by unscrewing the nut and slightly tapping the pin. A number of sizes can be obtained from the makers, the Hemming Conduit Grip Co. (Hatherton Works, Walsall).

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 2nd, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

4,352/14. Finding the Position of Ships at Sea. A. STCHENSONOVITCH AND SOC. DE CONSTRUCTIONS ELECTRO-MÉCANIQUES CI-DEVANT SOC. DUFILON, CONSTANTINOVITCH & CO. A method of determining the position of ships at sea by measuring the time lag between the reception of simultaneously-sent Hertz waves and submarine or other acoustic signals from two fixed points on the shore. (Nine figures.)

16,860/14. Protective System. SIEMENS-SCHUCKERTWERKE. Protective arrangements in which the time lag of the release of each of the circuit breakers depends on the current strength but has a lower limiting value, which is set in accordance with the position of the circuit-breakers in the circuit to be progressively greater for the circuit-breakers near the main busbars. (Five figures.)

19,729/14. Incandescent Lamps. DEUTSCHE GASGLÜHLICHT GES. (AUERGES.) Gas-filled lamps in which the bulb is provided with an elongated neck fitted with one or more internal baffle plates to keep the space near the seal of the leading in wires free from circulating currents of hot gas. (One figure.)

21,650/14. Cables. E. C. R. MARKS (*Aluminium Co. of America*). A composite cable for overhead work with stranded core and envelope of different metals laid up with an initial tensile stress on the strands differing according to the strength of the metals employed, so that each part of the complete cable bears such a proportion of the load due to ice and wind pressure that they all reach their respective elastic limits at the same time. (One figure.)

23,170/14. Bullet Localiser. D. FINDLAY. A probe consisting of a silver tube insulated from a central rod, the head of which protrudes from and is also insulated from the tube, is connected to a telephone circuit. A sound is heard in the telephone when the flow of current between the tube and the rod through the tissues is redistributed by the proximity of a metal object. (Four figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

DYNAMOS, MOTORS AND TRANSFORMERS: CREEDY [Variable pole machines] 18,887/14; PARSONS [High-speed rotors] 18,924/14; B.T.-H. CO. (G.E. CO., U.S.A.) [Speed control of motors] 19,057/14; WILSON AND WRIGHT [H. T. windings] 20,959/14; SVENSKA TURBINENFABRIKS AKTIEBOLAGET LJUNGSTRÖM [Motor regulation] 7,091/14.

Instruments and Meters: LANDIS & GYR [Prepayment meters] 18,464/14; ARM [H. C. meters] 20,786/14.

Switchgear, Fuses and Fittings: VON ARCO AND MEISSNER [A.C. Relays] 252/14; VAN HAERMEA BUMA [Mercury switches] 18,872/14; B.T.-H. CO. (G.E. CO., U.S.A.) [Electromagnetic] switches] 19,794/14; BENNETT and JEFFCOAT [Lampholders] 21,798/14; TUCKER and CRABTREE [Switches] 5,717/14; MIDGLEY and VANDERVELL [Lampholders] 8,332/14.

Telephony and Telegraphy: SYKES and FORD [Wireless telegraphy] 12,277/14.

Traction: GARDNER [Signalling] 18,954/14; MOSSAY [Tractors] B.T.-H. CO. (G.E. CO., U.S.A.) [Speed control of motors] 20,606/14.

Miscellaneous: HARRY W. COX & CO. and DONNITHORNE [Electro-medical apparatus] 18,660/14; MORTLEY [Dynamo-battery electric systems] 18,737/14; GREEN and LANDON [Mine signalling] 18,780/14; WALKER [Electric clocks] 19,818/14; GES. FÜR ELECTRO-OSMOSE [Electro-osmotic impregnation] 19,849 and 21,189/14; B.T.-H. CO. (G.E. CO., U.S.A.) [X-ray devices] 21,389/14; BENITEZ [Generation of currents] 5,591/14; MIDGLEY and VANDERVELL [Diaphragm horns] 7,088/14; LUND [Magnetic sun-dial] 8,052/14; CLAUDE [Neon tubes] 8,312/14; FRANKFURTER MASCHINENBAU, A. G. VORM, POKORNY & WITTEKIND [Coating electrically-worked tools] 9,477/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: A. E. G. [Enclosed arc lamps] 11,660/14.

DYNAMOS, &c.: U. S. LIGHT & HEAT CORPORATION [Dynamos] 11,510/14.

Miscellaneous: FRANKFURTER MASCHINENBAU A.G. [Electric tools] 11,264/14.

Amendments allowed

9,582/14. Electric Railways. R. E. STUART. Correction of a clerical error has been allowed in this specification, which is for a system of driverless railways for carrying mails, &c.

18,711/14. Wireless Telegraphy. W. C. WOODLAND. This specification has been amended by way of disclaimer. It describes a method of increasing the group frequency or tone pitch heard in the receiving telephone by dividing up a multi-phase alternating current at the sending end into a plurality of intermediate phases, and energising a corresponding number of oscillatory circuits successively.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:-

18,329/01. Circuit Breakers. B.T.-H. CO. (E. M. HEWLETT). A number of details of a form of automatic circuit breaker for heavy currents in the main and auxiliary carbon-copper contacts operated by independent toggle mechanisms and means to render the impedance of the auxiliary circuit as low as possible.

18,330/01. Train Control. B.T.-H. CO. (F. E. CASE). A complete multiple unit contactor control system for electric traction in which a separate reverser is not used.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: VOGEL [Flame carbons] 11,442/03.

DYNAMOS, MOTORS, and TRANSFORMERS: D. BALACHOWSKY and P. CLAIRE [Prevention of sparking] 23,743/02; V. A. FYNNE [Single-phase motors] 10,611/08.

Electrochemistry and Electrometallurgy: L. TRINKHARN [Electro-deposition] 11,498/06.

Incandescent Lamps: B.T.-H. CO. (G.E. CO., U.S.A.) [Squirted filaments] 11,409/06; SIEMENS & HALSKE A.G. [Tungsten filaments] 11,716/07.

Telephony and Telegraphy: A. POLLAK, G. EGGER, and F. SILBERSTEIN [Developing photographic records from high-speed telegraph receivers] 11,596/02.

Traction: SIEMENS-SCHUCKERTWERKE GES. [Interpole traction motors] 9,637/08; E. M. MUNRO and RAILLESS ELECTRIC TRACTION CO. [Current collectors] 11,947/09.

Miscellaneous: A. J. BOULT (H. S. MILLS, U.S.A.) [Electric automatic violin player] 10,618/05; W. K. KEYS (GENERAL ACOUSTIC CO.) [Microphones] 11,754/07; F. DOGILBERT [Electrical apparatus for production of music sheets] 11,811/07; NEW IGNITION SYNDICATE and W. J. L. SANDY [Primary batteries] 11,035/08; B. E. R. NEWLANDS and R. M. PARKINSON [Primary batteries] 11,926/09.

CATALOGUES, PAMPHLETS, &c., RECEIVED

INDUSTRIAL LIGHTING.—An interesting booklet from Holophane, Ltd. (12 Carteret Street, Queen Anne's Gate, S.W.), deals with the application of special forms of the well-known Holophane prismatic glass reflector to the lighting of industrial premises. The type of reflector dealt with consists of the ordinary glass reflector of the intensive, extensive, focussing, and other types over which aluminium cases are spun in such a manner that they completely seal up both ends of the reflectors. This of course in no way interferes with the efficiency of the inner reflecting surface of the glass, and protects the outer surface from dust. The little work is a great deal more than a catalogue of these excellent reflectors, but gives a quantity of well-chosen and well-presented information on works lighting, particularly as regards the degree of illumination admissible with different classes of machinery, &c., while the curves and tables worked out for each design of reflector enable the height, spacing, &c., of any size of lamp up to and including the large "half-watt" units in any style of reflector to be readily ascertained. The importance from a manufacturing efficiency point of view of adequate and correctly directed lighting is now too well known to need insisting on here.

DYNAMO MANUFACTURERS' MACHINERY, &c.—A number of special machines for the equipment of electrical manufacturing works are put forward in a catalogue from

INGRAM'S INDIA-RUBBER GLOVES and GAUNTLETS FOR ELECTRICAL PURPOSES

NON-CONDUCTING.

Made in

SAM FAY, General Manager.

Neville's, Ltd. (Liverpool). The list is very extensive, and includes coil-winding machines in a great number of sizes for both field coils and arc lamp, bell, and other small coils, taping machines for armature coils, &c.; armature banding lathes, papering machines for core plates, circle and ring shearing machines, and armature disc notching presses. Other special plant comprises hydraulic presses for forcing armatures on and off shafts, vacuum drying and impregnating plant, bending and sawing machines, &c. We understand that the greater proportion of this machinery is of British manufacture.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

ELECTRIC HEATERS.—The Bastian Electric Heating Syndicate, Ltd. (185 Wardour Street, W.), have issued a new catalogue of their well-known "Quartzalite" heating apparatus. Many designs of radiator are included which employ the Bastian glower consisting of an elongated helix of a special wire supported by a quartz tube, and mounted in clips. A number of the designs have been specially prepared for shipboard work, and a newer form of heater in which the elements are enclosed in iron pipes is made for the heating of large premises where a considerable radiating surface at a moderate temperature is an advantage. The latest forms of the well-known "Pygmy" hot plate and larger sizes of electric stoves, as well as ovens, water heaters, irons, and kettles, are also represented. The firm now announces a uniform trade discount of 20 per cent. off the prices of all their apparatus, instead of the varying discounts prevailing hitherto.

ACCUMULATOR ACCESSORIES.—A leaflet from Cookson & Co., 25 New Oxford Street, lists a number of accessories for the accumulator trade, including india-rubber corks and collars, glass vents, hydrometers, voltmeters, &c.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Amble.—Having had a disagreement with the Gas Company with regard to its street lighting contract, the Council is attempting to obtain a supply of electrical energy from the Broomhill Collieries, Ltd. The Surveyor is preparing estimates of the cost of street lighting.

Bury.—Extensions at the electricity works estimated to cost £7,225 have been sanctioned by the L.G.B.

South Africa.—The Johannesburg Council requires 1,000 single-pole 25-ampere house service cut-outs. Further particulars at 73 Basinghall Street, E.C.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Airdrie.—Garage and offices (£2,400). Airdrie & Coatbridge Tramways Co.

Dundee.—Cinematograph theatre in Gray Street. Broughty Picture House, Ltd.

Edmonton.—Extensions to military hospital (£9,000).

Manchester.—Cinematograph theatre, Hulme. Architect, P. Cummings.—Cinematograph theatre, Oxford Road. Architects, T. Cook & Sons.—Factory, Cheetham. Architects, Thorpe & Collier.

Wigan.—New spinning mill. Northern Coarse Spinners, Ltd., 51 King Street.

Miscellaneous

Burnley.—Electrical goods for the Board of Guardians.

Edmonton.—Six months' supply of electric lamps for the Guardians. Clerk, White Hart Lane, Tottenham. Sept. 22nd.

London: Kensington.—Six months' supply of electrical fittings and lamps for Guardians. Clerk, Marloes Road. Sept. 23rd.

New Zealand.—A Government Department requires electrically-driven letter sealing machines. The type at present in use is of foreign manufacture, but it is not so durable as could be wished, and no spare parts are obtainable. Communications to H.M. Trade Commissioner for New Zealand, P.O. Box 369, Wellington.

Warrington.—Electrical goods for the Board of Guardians.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. Geo. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £82 to £83 (last week, £84 to £85).

Liquidation.—Mr. Arthur Faraday Hawdon, Electrical Engineer, Elmfield Gardens, Gosforth, Northumberland, has been adjudicated a bankrupt.

APPOINTMENTS AND PERSONAL NOTES

Mr. C. L. Oechsner, who has for many years been in charge of the Rugby advertising of the British Thomson-Houston Co., left last Thursday on his way to Boston, from whence he proposes to go to Schenectady and New Orleans, then to the Pacific Coast, California, and to come back again via New York.

The works' employés of J. H. Tucker & Co. (Hay Mills, Birmingham) have presented Mr. J. B. Tucker, who is the son of the founder and present head of the firm, and holds a commission in the R.E., with a service revolver on the occasion of his leaving for the Front. The office staff presented him with a silver cigarette case, and the officials of the firm asked his acceptance of a sword, sword knot and scabbard, suitably engraved. The presentations were made on Friday last amid great enthusiasm.

An electrical engineer is required for lecture and laboratory work in the evening technical class of the North-Eastern Railway Institute, York. Applications to the Secretary.

We are informed by the Magneta Time Co., Ltd. (14 Soho Square, W.), that Mr. W. J. Polyblank is no longer in any way connected with this Company.

Switchboard attendants are required in the West Bromwich and Stockport Electricity Departments. Applications in both cases to Borough Electrical Engineer.

LOCAL NOTES

Aberdeen: *Reduced Electricity Revenue.*—The Electricity Committee, like so many others, is faced with the difficulty of meeting the increased cost of coal, etc., but prefers to add 15 per cent. to the consumers' accounts rather than to increase the actual charges per unit.

Accrington: *Showroom.*—A sub-committee has been appointed to consider the question of whether the Electricity Department's showroom shall be continued.

Belfast: *The Fire at the Electricity Works.*—At the meeting of the Corporation last week some serious suggestions were made with regard to the fire at the electricity works coal bunkers, reported in our last issue, and as a result it was decided that the whole of the facts regarding the outbreak should be inquiry into specially.

Dublin: *The Lighting Committee.*—A recommendation is to come before the Corporation for the amalgamation of the Lighting Committee with the Electric Supply Committee.

Eastbourne: *Economy in Electricity Department.*—In reply to a request from the Finance Committee, the Electrical Engineer reports that all possible economies in expenditure on permanent works have already been considered and made. The Electricity Committee has decided to postpone the purchase of a new boiler, chimney, and auxiliary plant, together with the extension of the cooling pond and tower, and it is not anticipated that any large expenditure will be required during the present financial year.

Eccles: *Electricity Accounts.*—There was a net profit of £632 on working of the electricity undertaking last year after meeting capital charges.

London: *Fulham: The Linking-up Scheme.*—Some difficulty appears to have arisen with regard to the completion of the linking-up scheme between Battersea, Fulham, and Hammersmith, of which particulars have already been given in our columns. The London County Council and the Board of Trade have agreed to the scheme, but the Hammersmith Council proposes the insertion of a clause in the agreement to the effect that in the event of Hammersmith not receiving sanction to incur the necessary expenditure to enable it to join in the scheme within the next three or four months, such agreement should not be binding upon Hammersmith, and it would therefore drop out of the scheme. The Fulham Council, however, regard this as likely to lead to unforeseen complications, and has passed a resolution rescinding the previous agreement to join with Battersea and Hammersmith, and proposes to proceed with the scheme with Battersea alone. Contracts have already been entered into with W. T. Henley's Telegraph Works Co., Ltd., and the British Electric Transformer Co.

Hampstead: *Reduced Electricity Revenue.*—In consequence of the reduced lighting due to the war, the number of units sold last year dropped by some 322,000 units, and the revenue was likewise less. The net surplus was £2,767 as against £6,258 in the previous twelve months. The expenditure increased mainly in respect of management expenses and active service pay.

Lytham: *Bulk Supply.*—The L.G.B. has now intimated that it is unable to sanction a loan for the scheme under which the St. Anne's Council would have supplied Lytham with electricity in bulk.

Manchester: *Proposed Investigation Committee.*—The motion by Councillor Ross Clyne for the appointment of a Special Committee to inquire into the working and control of the Electrical Department, together with the appointment of an individual expert, referred to on page 334 of our issue for August 5th, duly came before the monthly meeting of the Corporation last week. It met, however, as was not altogether unanticipated, with little sympathy, and eventually was rejected, only the proposer and seconder of the resolution voting for it. As we pointed out in our issue for August 5th, the resolution was partly aimed at the proposal to build the new Barton Power House for which the Treasury's consent has now been obtained, and against which there has been a certain amount of opposition by the Ratepayers' Association. Against this small amount of opposition is the fact that the demand for electricity in Manchester is necessarily making huge strides, and manufacturers of munitions in the area have pointed to the great harm which would be done if the Barton Power House is not proceeded with.

Swansea: *Increased Cost of Production.*—The Electricity Committee has considered a suggestion by the Borough Electrical Engineer to meet the increased cost of production due to the war amounting to £4,400 for the current year. A scheme of increased charges, together with the application of a meter rent, is estimated to bring in about £3,300, which, added to the profit calculated for the year, will be sufficient to meet the increased expenditure. The recommendation has been adopted and will become operative from the September meter reading.

Warrington: *Improved Coal Consumption.*—The report of Mr. F. V. L. Mathias, the Borough Electrical Engineer, upon the working of the electricity undertaking for the year to March 31st, shows that there was a net profit of £1,819 after meeting capital charges. The coal consumption shows the satisfactory improvement of 6 per cent., the quantity burned per unit generated being 3.98 lbs.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Clyde Valley Electrical Power Co.—The profit for 1914, including £11,535 brought forward, was £54,095. After transferring £18,709 to depreciation, it is proposed that £4,276 be placed to reserve, £10,000 applied for writing down legal expenses, the dividend on the preference shares to October 31st, 1915, to be paid, and £12,450 carried forward.

British Electric Transformer Co.—An interim dividend at the rate of 6 per cent. per annum, less tax, on the ordinary shares for the past half year is declared.

SUMMARY

THE number of names on the register of the Electrical Emergency Service now considerably exceeds the demand, and, until more central stations adopt the scheme, we can hold out little hope of finding active work for those offering part-time service. Readers desiring to offer full-time service as charge or shift engineers at central stations, or as switchboard attendants, are recommended to insert and reply to advertisements in the ordinary course (p. 377).

THE first report of the Home Office Committee on Lighting of Factories and Workshops has been issued. The necessity of adequate lighting is insisted on, and minimum values of illumination to be observed in different circumstances are specified (p. 378).

SOME particulars of the Barton power station now being built for the Manchester Corporation Electricity department were given in a Paper before the British Association by the Chief Engineer, Mr. S. L. Pearce (p. 379).

OTHER Papers read before the Engineering Section included a description of a self-adjusting commutating-pole system by Prof. Miles Walker, an account of experiments on the heating of iron by high-frequency magnetisation by Mr. N. W. McLachlan, and one giving results of experiments regarding the effect of triple frequency currents on transformer core losses by Messrs. H. M. Lacey and C. H. Stubbings. Prof. E. Wilson also gave results of exposure tests of certain aluminium alloys (pp. 379, 380).

A REPORT presented to the Economics Section of the British Association deals with the employment of

women in the electrical industry before, during, and after the war (p. 380).

A POINT connected with the rating of crane motors is discussed in our Questions and Answers columns (p. 381).

AMONG the subjects of specifications published at the Patent Office last Thursday are relays for wireless telegraphy, A.C. motors, X-ray tubes, and locking lamp-holders (p. 382).

THREE Papers on wireless telegraphy read before the British Association are referred to under "Telephony and Telegraphy" (p. 382).

CABLE is required at Worcester; boiler feed-pump and cooling tower at Wakefield; a number of Guardians in various parts of the country require lamps and electrical fittings; and there is the probability of electric omnibuses being adopted at Burton-on-Trent (p. 383).

THE St. Pancras Electricity Committee proposes to allocate the available balance, less £4,000, to relief of rates.—It is stated that Parliamentary powers are to be sought for a water-power scheme in Ireland.—The Edinburgh Electricity Committee has called upon its coal contractors to supply at a price in accordance with the Act limiting prices (p. 384).

An interim dividend of 5 per cent. is recommended by the British Insulated & Helsby Cables, Ltd. (p. 384).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK ENDING SEPTEMBER 25TH, 1915,
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Drills, 6.30 to 7.30; 7.30 to 8.30.

Monday: Section III., technical instruction. Section I., musketry at range. Sections II. and IV., squad drill or signalling.

Friday: Section IV., technical instruction. Section II., musketry at range. Sections I. and III., squad drill or signalling.

Attention is called to the fact that the War Office has now decided to employ certain Volunteer Training Corps in guarding waterworks, railways, and prisoners.

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

Obituary.—Not long after the death of Mr. R. Kaye Gray, of the India Rubber, Gutta Percha, and Telegraph Works Co. (Silvertown), there has passed away, in Mr. Matthew Hamilton Gray, his younger brother, who died at the age of 61 in Scotland on Sept. 2nd, and was buried at East Wickham on Sept. 6th. Like his brother he had played a prominent part at the Silvertown works, but had retired from active work there some seven years ago. His early career was that of a mining engineer, but subsequently he specialised in submarine cable work, and, first as assistant and then as chief engineer, he supervised the cable-laying and repairing operations of the Silvertown fleet in many parts of the world.

THE ELECTRICAL EMERGENCY SERVICE

FOR the past few weeks, nothing has appeared in our columns with regard to the Electrical Emergency Service inaugurated by us last April. A considerable number of our readers, who offered their services to fill the gaps caused by switchboard attendants joining the colours, have been working in this capacity for some months, and their action has been greatly appreciated. There are many more, however, whose assistance, offered with equal willingness, has not been called for, although their names have been on the register of the Electrical Emergency Service for many weeks. To these a few words of explanation are due.

As our readers already know, one of the immediate results of the declaration of war last year was the calling up of a large number of Navy and Army reserve men engaged at central stations and sub-stations, and the enlistment of numbers of the younger men. The switchboard staffs were being depleted at a very rapid rate, and although it was at the period of light summer load, it was soon evident that the situation was one to be regarded with some apprehension. The more or less automatic adjustment took place at first: men transferred from the provinces to London and from smaller stations to larger ones, and the smaller stations filled up the gaps to some extent from outside or found other means to meet the emergency. With the increasing load—not only the normal increase, but also the growing power load for works manufacturing war material—it soon became apparent that some more definite step was necessary, and, with the exception of the works supplying nothing but tramways, permission for men to leave was refused, and the War Office issued instructions to recruiting officers not to accept employés of electricity works for enlistment. Many men of military age and capable of making good soldiers were thus prevented from joining the colours, and the main object of our Electrical Emergency Service was to enable the electricity works to give permission to enlist with greater freedom. We enrolled in the service men possessing electrical experience and able to take over switchboard duties with little or no additional training or instruction, in some cases for full-time and in other cases for part-time work. The scheme has worked well up to a point, but it was soon found that the electricity works who had power to exercise their veto mostly preferred to keep their present men rather than to incur what they thought would be the risk of relying on the work being done by men who had not recently been in charge of switchboards. Casual vacancies are now so relatively few that they are being filled up by the insertion of advertisements in the ordinary course. Although, therefore, as we have said, many men in the Electrical Emergency Service are doing good work on central station switchboards—both in electricity and tramway stations—yet we have many more on the register waiting for their services to be accepted by the adoption of our scheme by additional central stations.

Incidentally, we may mention that, in selecting the names from our register for enrolment as active members of the Electrical Emergency Service, we have given the preference to men who are over military age or are prevented from joining the Army or Navy by some other good reason, and that, in many cases, our insistence on this has had the result of sending recruits directly as well as indirectly to join the forces. In other cases, readers who have been unable to find employment in the Electrical Emergency Service have joined the ranks of munition workers.

To aid us in keeping the register of our Electrical Emergency Service in order and up to date, we beg any of our readers who have been placed on the register and have since found other employment for their spare or full-time activities to notify us as soon as possible.

THE LIGHTING OF FACTORIES

THE first report of the Home Office Committee on lighting in factories and workshops has now been issued. This committee was appointed in 1913 and consisted of Dr. R. T. Glazebrook, Mr. L. Gaster, Prof. E. Gotch, Mr. J. H. Parsons, Mr. W. C. D. Whetham, and Sir Arthur Whitelegg (Chief Inspector of Factories). On the death of Prof. Gotch, Prof. C. S. Sherrington was appointed. Mr. D. R. Wilson (Inspector of Factories) and Mr. C. C. Paterson (National Physical Laboratory) acted as secretaries.

The inquiry in the first instance was limited to the engineering, textile, and clothing trades. A large number of factories were visited, and experiments were conducted at the National Physical Laboratory. Investigations were also made, which showed that a considerable number of accidents,

in which inadequate lighting was a contributory cause, occur every month, and that bad lighting has harmful physiological effects on workers, while good lighting conduces to cleanliness, health, and manufacturing efficiency.

The committee recommends that there should be a statutory provision: (a) requiring adequate and suitable lighting in general terms in every part of a factory or workshop, and (b) giving power to the Secretary of State to make Orders defining adequate and suitable illumination for factories and workshops or for any parts thereof or for any processes carried on therein.

Broadly, the illumination may be said to be adequate and suitable provided that it is sufficient for the proper carrying out of the work both as regards quality and output, and there are no lighting conditions prejudicial to the health, comfort, and safety of workers.

The recommendations further lay down that in order to satisfy these requirements, the illumination should comply with the following requirements: . adequacy; a reasonable degree of constancy and uniformity of illumination over the necessary area of work; the placing or shading of lamps so that the light from them does not fall directly in the eyes of an operator when engaged on his work, or when looking horizontally across the workroom; the placing of lights so as to avoid the casting of extraneous shadows on the work.

The following recommendations define the minimum illumination implied in the terms adequate and suitable in different circumstances: over the "working areas" of workrooms the illumination measured on a horizontal plane at floor level shall not be less than 0'25 foot-candle, without prejudice to the illumination required for the work itself; in all parts of foundries in which work is carried on or over which any person is ordinarily liable to pass, the illumination measured on a horizontal plane at floor level shall not be less than 0'4 foot-candle; in all other parts of factories and workshops over which persons employed are liable to pass the illumination measured on a horizontal plane at floor level shall not be less than 0'1 foot-candle; in all open places in which persons are employed during the period between one hour after sunset and one hour before sunrise, and in any dangerous parts of the regular road or way over a yard or other space forming the approach to any place of work, the illumination on a horizontal plane at ground level shall not be less than 0'05 foot-candle.

These values are suggested without prejudice to the special illumination required for the carrying out of the work, which naturally varies greatly according to the nature of the operations. At present the Committee are not prepared to recommend standards of illumination for these purposes, which require further investigation. A further recommendation provides for exemption of individual cases, and of factories to which the above requirements could not be applied, and the case of shipbuilding yards is to receive separate consideration. Finally, suggestions are made for the periodic cleaning of windows.

In conclusion, the Committee point out that the minimum values prescribed are considerably lower than those proposed by many witnesses and are also lower than those found to exist in the majority of factories visited. In many cases manufacturers would naturally prefer to provide a substantially higher value than that indicated. The intention has been to propose values which can be adopted as a practical legal minimum without causing hardship, and would serve the purpose of raising the level of illumination in those factories which are behind modern practice in regard to methods of illumination. The Committee did not feel justified in drawing any distinction between direct, indirect, and semi-indirect lighting, nor between systems which differ in the colour composition of the light. Similarly the standards are intended to apply equally to natural and artificial lighting; that is to say, when the natural illumination falls below the prescribed limits, it must be supplemented or replaced by artificial illumination.

Data are given in appendices to the report which will be of service to those engaged in designing new factories and in examining the adequacy of lighting in existing buildings.

Meter Approved.—The Board of Trade has approved of the Murday recording volt-meter types M.R.1 and M.R.2 for continuous current and alternating current respectively.

Engineers in the American Army.—It is announced in the proceedings of the American Institute of Electrical Engineers that a movement is on foot for the formation of a United States National Reserve Corps of military engineers. A joint committee has been formed among the American Engineering Societies.

THE BRITISH ASSOCIATION AT MANCHESTER

A NUMBER of Papers of electrical interest were read at the meetings of Section G (Engineering), on Thursday, Friday, and Saturday of last week. The proceedings on the Wednesday commenced with the reading of Dr. Hele-Shaw's Presidential Address to the Section, referred to on page 370 of our last issue.

The New Manchester Electricity Works.

At the meeting on Thursday an interesting account was given by Mr. S. L. Pearce (City Electrical Engineer, Manchester) of the new Barton power house which is building for the Corporation. This scheme has received a good deal of public attention in Manchester since its inception, but the Treasury consent to borrow the necessary money has now been obtained, and the preliminary work is well in hand. At the same time, owing to the conditions, considerable delays are anticipated in completion.

The power house is being arranged for an ultimate plant capacity of 160,000 kw., and the first section will accommodate 30,000 kw. Purified sewage effluent is to be used for condensing purposes, this expedient having been forced upon the Electricity Department by reason of the refusal of the Manchester Ship Canal authorities to consent to the canal water being used. The preliminary plans of the generating station show it to be essentially a big unit station. It is proposed to erect it in four sections, each of which will contain two complete steam raising, electrical generating, and auxiliary plants, there thus being eight complete plants in the station. This will allow of one spare plant, one set for repairs, and six in commission. The first four generating sets will each have a capacity of 15,000 kw., the remaining four each being rated at 25,000 kw.

Provision is made for four boiler houses, each with two batteries of water-tube boilers facing a central firing floor, with four coal silos. There will be one battery of boilers to each generating set, or one boiler house for every two turbines. The preliminary estimates show that 500,000 tons of coal per annum will be required by the complete plant, coal being brought both by the Bridgwater Canal and the Lancashire and Yorkshire Railway. The coal silos will hold two months' supply of fuel outside the boiler houses, there being at the same time thirty-six hours' bunker capacity in the boiler houses. The suction system for the removal of ashes is proposed. The first section will contain eight boilers, each with a normal capacity of 50,000 lbs. of steam per hour, and a maximum capacity of 60,000 lbs. per hour. Each boiler will be complete with its own superheater, economiser, and induced draught plant. As regards the proportion of boiler-heating surface to grate area provided, attention was called to the higher proportion in the States and on the Continent, compared with this country, it being pointed out that at the Detroit power house the proportion is 60 to 1; at the Fisk Street station of the Chicago Edison Co. it is 44 to 1; whereas in the new Barton power house it will be 35 to 1. The coal silos have one novel feature, viz., the provision of three-armed distributors, through which the silos are filled, instead of one shoot. The object is to assist in keeping the level of the coal across the silo more or less even and so reduce the labour required for trimming.

The first generating sets will be two 15,000 kw. turbo-alternators, three phase, 6,600 volts, 50 cycles, running at 1,500 r.p.m., and developing the normal output at 0.85 power factor. Turbine progress in this country, said Mr. Pearce, certainly seemed to be overshadowed by the developments in the States, where the General Electric Co. of Schenectady is building a 30,000 kw. machine for the Commonwealth Co. of Chicago, and a 35,000 kw. set for Philadelphia, whilst 50,000 kw. sets had been designed for the New York Edison Co. The most surprising thing about the new Manchester turbines, however, was the increased speed, the blade velocity amounting to 700 ft. per second. The steam consumption was calculated to be about 11 lbs. per kw.-hour. Wet air filters will be used in connection with the ventilation of the generators.

An unusual feature in design will be the design of the pump hall, in which all boiler and feed pumps, hot well and reserve feed water tanks will be placed, in addition to the apparatus for testing the steam consumption, &c.

At the north-western end of the station will be a sub-station for supplying the current required in the station, and there will also be a 3,000 ampere-hour battery for general continuous-current supply and excitation.

Between each pair of turbines there will be an open well containing the condenser and auxiliary plant, and between the first turbine and the sub-station there will be a rail track connecting with the general workshop forming a continuation of the switch-house.

For the sewage effluent for condensing-water purposes, a pumping station will be built at Davyhulme, from whence the purified effluent will be pumped to Barton. The discharge from

Barton back to Davyhulme will take place at a substantially higher level than the intake. Owing to this increase, the capacity of the sewage works will be automatically enlarged and the discharge effluent will have a temperature some 15° or 20° higher than the intake. This, again, will result in advantage to the Rivers Committee, for the consulting chemist to that body states he will be able to effect economies in the subsequent purification processes by reason of the higher temperature.

The main cables from the generators will run direct to step-up transformers, transmission taking place at 33,000 volts. The switchgear will be of the oil-immersed remote-control type, operated from a control gallery overlooking the engine-room.

Estimates of total costs give a figure of £1,775,000, this amounting to £11.09 per kw. of rated load and £8.8 per kw. of overload. These figures compare with £12.26 and £9.81 for the London County Council power scheme, in which a total capital expenditure of £1,471,260 was contemplated. Works costs are put at 0.138d. per unit on a 40 per cent. station load factor. To this is added 0.88d. per unit for capital charges, making a total of 0.226d. per unit, apart from administration expenses, compared with 0.353d. at the Stuart Street station of the Corporation at present. The difference on the present output would amount to £60,000 per annum.

The papers of electrical interest referred to below were also read before the Section on Friday. Several others relating to wireless telegraphy are dealt with on another page of this issue under "Telephony and Telegraphy."

Heating of Iron by High-frequency Magnetisation.

A paper by Mr. N. W. McLachlan described experiments illustrating the heat produced when iron is magnetised by alternating currents, with frequencies of the order of $2 \text{ to } 5 \times 10^3$ cycles per second. The magnetising current was obtained by a Poulsen-arc generator connected across 240 volts D.C. In order to demonstrate the extent of the losses, a magnetic heater or boiler, consisting of a solenoid wound on a glass tube containing water and a number of iron strips or wires, was inserted in the shunt circuit of the generator. A short time after the shunt circuit was closed the water began to boil. An experiment was also arranged to show the variation in permeability of iron with variation in temperature. A ring of Lohys (mild steel), insulated with asbestos and wound with a number of turns of copper wire, was connected in the shunt circuit of the generator. By passing a large current through the winding of the ring, thereby obtaining a strong magnetising force, the magnetisation losses were such that a rapid rise in temperature was produced, causing the iron to attain a bright red heat. The variation in permeability corresponding to the rise in temperature may be followed by observing the current in the shunt circuit and the voltage across the terminals of the ring. Data, including the watts lost per kg., are given, which enable the changes to be followed. For example, let a frequency of 1.9×10^3 with $B_{max} = 3,500$, the watts lost per kg. worked out at 48,000.

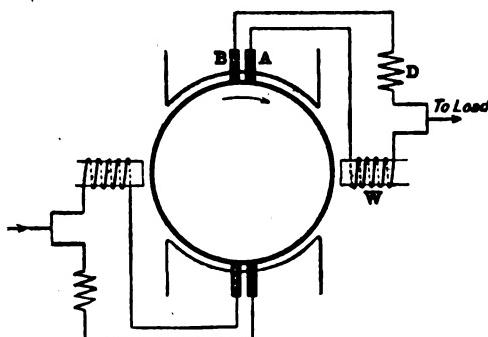

In the discussion which followed, Prof. E. W. Marchant (Liverpool) said that the important fact which emerged from these results was that the quality of iron with varying temperature was evidently very much the same as it was at ordinary low frequencies. It was found, however, almost impossible to calculate the true permeability of the material because of the enormous skin effect which led to surprisingly high power factors of coils with iron cores at very high frequencies. Prof. Gisbert Kapp said that the difficulty was in a machine which contained iron to work with a frequency of 200,000 or 250,000 without having an enormous loss of power due to hysteresis and skin effect. Experiments in wireless showed that the ordinary laws did not hold good, and the problem was to determine how the loss increased with the frequency.

A Self-adjusting Commutating Device.

A paper with this title was then read by Prof. Miles Walker. He pointed out that a continuous current generator with commutating poles will not commute very heavy over-loads, owing to magnetic saturation of the inter-poles interfering with the proportionality between the current commutated and the commutating flux. The paper described a device tried at the Manchester School of Technology which automatically produces the right amount of commutating flux over very wide ranges of load. Each brush consists of two parts, one part, A, being slightly in advance of the other on the commutator, and lightly insulated from it. The winding on the commutating pole has twice as many turns as it would ordinarily have, and the cross-section of the copper conductor is only sufficient to carry one-half of

the armature current. The part of the brush B may be connected through a diverter D, having the same resistance as the winding W, or the diverter may be dispensed with altogether. The direction of rotation of the machine is such that a point on the commutator passes first under B, then under A.

Assuming that the number of turns on the commutating pole is such as to give the right commutating flux when half current is passing through them, then it will be found that the current will divide evenly between brushes A and B, because the correct excitation of the commutating pole gives

A SELF-ADJUSTING COMMUTATING DEVICE.

an even distribution of current over the face of the compound brush AB. If, however, the number of turns in W is too great, there is a tendency to over-commutation; that is to say, the current in B becomes greater and the current in A less. This has the effect of automatically weakening the commutating pole, which remains of just such a strength as to bring about the required distribution of current between A and B. If for any reason the commutating pole tends to become too weak, owing, let us say, to the saturation of the iron of the pole, the induction of the armature coils carries the current forward to brush A, and tends to increase automatically the excitation of the commutating pole.

In the discussion Mr. G. G. Stoney, F.R.S., said that having a double brush would probably make it possible to increase the brush area. It was one of the bugbears of the designers of turbo-generators to get sufficient area on the brushes. He asked whether, in the case of a machine with both commutating poles and compensating windings, the author's device would supply the current to both. Narrow brushes, in his experience, ran better than wide ones. Mr. McCall thought that the method might be carried still further to get higher connecting voltages to deal with temporary overloads.

Prof. Miles Walker, replying, said the apparatus had not yet been tried for D.C. turbo-generators, and pointed out that these were not now made except in small sizes. It would be possible to connect the apparatus so that the current from the forward brush went through the compensating winding as well as the commutating pole. In a continuous-current generator it was necessary to put enough turns on the commutating pole to compensate for the armature, and that was a distinct advantage in connection with this apparatus, because the very slightest change in the proportionality of the current between the two brushes gave the effect required. He did not think that the increase in the proportion of the commutating current advocated by Mr. McCall was necessary.

Transformer Core Losses and Triple Harmonics.

Experiments on the effect of triple frequency harmonics on core losses in transformers were described in another Paper read the same day before Section G by Messrs. H. M. Lacey and C. H. Stubbings. An alternator giving approximately a sine wave was three-phase star connected to a three-phase choking coil. The star centres were also connected through a switch, and experiments were made with this switch open and closed. In each case the wave forms of phase amperes, phase volts, and in the second case amperes in the neutral wire, were taken by means of a Kelvin quadrant electrometer and a contact-maker. It was found upon analysing the various wave forms that in the first case there was a 48·9 per cent. triple harmonic in the volt curve but practically none in the current curve. In the second case there was practically no triple harmonic in the volt curve, but 48·2 per cent. in the current curve; also the wave of current in the neutral wire was very nearly a sine wave of triple frequency, and having an amplitude of approximately three times that of the triple harmonic in the current curve. This shows that the existence of a neutral connection enables a triple harmonic to exist in the current curve, and also that the suppression of this harmonic from the current curve forces it into the volt curve. Using these curves, the induction curves for the two cases were drawn, and from these the hysteresis loops (including eddy current losses) were obtained. The areas of the two loops were measured, and the ratio of the areas

case 1 : case 2 was found to be 0·775, thus showing that by insulating the star centres a saving of 22·5 per cent. in the core loss is obtained, the voltages being equal. The watts supplied in the first case were 24·3 per cent. less than in the second case, the average watts being found from the curves. The results of these experiments point to the fact that from the point of view of core losses the star centres in three-phase systems should be insulated.

Exposure Tests of Aluminium Alloys.

Prof. Ernest Wilson, in a Paper read at the same meeting, described the results of exposure tests of wires of various materials left exposed to the London atmosphere on the roof of King's College during the last fourteen years. Commercial aluminium increased its electrical resistance by 17·2 per cent. in thirteen years. The copper-aluminium alloys became so corroded as to be useless; a copper-manganese alloy had increased its resistance about 10 per cent. in thirteen years; and copper-manganese-magnesium (duralium) alloys 9·6 per cent. in four years, but had become brittle. Copper-nickel and copper-zinc-nickel alloys had somewhat increased their resistance.

Mutual Induction between Masses.—Among the Papers before Section G on Saturday was one by Prof. Miles Walker, describing some curious experiments to determine, in view of the closeness of the analogy in the behaviour of matter in motion and electricity flowing in a circuit, whether there is any action between masses analogous to the mutual induction between electric circuits—that is, if we accelerate a fly-wheel whether it produces any force upon an adjacent co-axial disc. No such force of measurable magnitude was detected.

A Cadmium Vapour Arc Lamp.—Before Section B (Chemistry) on the Wednesday, Dr. H. J. S. Sand exhibited a cadmium vapour arc lamp, the use of which is recommended for polarimetric and other purposes, is comparable in general principle with the well-known mercury vapour lamp. The lamp is constructed of quartz-glass, and the cadmium is freed from oxide and dissolved gas by a process of filtration while at the pump. It is hindered from adhering to the glass by the presence of a small amount of a loose powder (zirconia) in the lamp. The metal is melted by external heating before starting, and maintains itself in the molten condition by the heat of the current. Once started the lamp may be kept burning for an indefinite time.

It has been decided to hold next year's meeting at Newcastle-on-Tyne under the Presidency of Sir Arthur J. Evans, and the 1917 meeting at Bournemouth.

EMPLOYMENT OF WOMEN IN THE ELECTRICAL INDUSTRY

THE draft interim report of a Committee appointed by the British Association to investigate the question of women labour both before and after the war, dealing with the electrical apparatus industry (presented to Section F, Economics), gave the following figures of men and women employed in the electrical industry for 1911:—Electric cable manufacture, 4,858 men and 955 women; electric lamp manufacture, 5,627 men and 4,202 women; other electrical apparatus and electrical fittings, 50,341 men and 4,118 women. The total number of women is thus 9,275, which compares with a total of 2,490 given for 1901. The report goes on to state that women are to some slight extent doing work which before the war was done by men, such as small lathe work, screw machine, cable-making, winding of transformers and armatures. This last may be regarded as an extension of work previously done by women. Before the war, women were definitely employed in all branches of light work in electrical apparatus work, but not at all in the electrical supply trade. Although the above displacement is classed as owing to the war, there is evidence that before August, 1914, the policy of many firms had been to extend the employment of women into new branches. That women have to some extent been replacing men, or entering new branches, may also be inferred from the fact that, though the electric lamp branch of the trade has been depressed owing to the war, there has been a total increase in the employment of women in the electrical trade of nearly 18 per cent. Part of this increase is due to a temporary increase of production in branches of the trade in which women were previously employed, but as the enlistment of men from this trade has been on a considerable scale, it is reasonably clear that women are to some extent taking their place during the emergency. In most cases readjustment to meet the introduction of women has been simple, or no alterations at all have been necessary. One firm has actually made the machines more mechanical and employs an extra mechanic as supervisor. The introduction of women into new processes often necessitates the provision of another workshop, as in the majority of cases it is not considered desirable for men and women to work together.

The main objections to the employment of women are given as want of technical skill and general experience, want of physical strength, objection on the part of employers to have men and women working side by side, men's objection to the introduction of women. In regard to the question of physical strength, one firm employing women in lathe-making found

the women's output slightly less than that of men, owing mainly to exhaustion during the last hour of work. Nevertheless, it is clear that as a general rule women's output is considerably less than that of men, since both on time and piece rates their wages are generally 50 per cent. below those of men. The main advantages are:—Their greater dexterity in certain processes where small fingers are an advantage. This has been a considerable factor in the employment of women in such processes as assembly work in the electric lamp trade. Cheapness of their labour. The larger supply of unskilled workers to draw upon.

In those processes which are suitable to women, continues the report, the possibilities of extending their employment are great. In the more skilled processes, however, where a longer training is necessary, it depends how far women choose to utilise the present opportunity of becoming highly efficient workers. Hitherto women have been employed almost entirely in unskilled processes, and the trade has been essentially one for young persons, the majority of the girls leaving the trade soon after the age of nineteen. It is difficult to foretell the state of trade after the war, but in view of the accumulation of private work which cannot be done at present, employers rely on its being good for at least a year or two, and they therefore expect to absorb the men returning from the Front as well as the new women that have been taken on.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

QUESTION No. 1,460.

I have a 100 volt 50 ~ small table fan (series wound) which will not run on a 105 volt 83 ~ current. Is this due to the difference of the currents, or is there a fault in the fan? A current passes, causing the fan to hum. What is the general effect of a change of voltage and change of periodicity on such a motor? Should a similar 100 volt D.C. motor run on 100 volt 50 ~ A.C. circuit?—K. E. N.

(Replies must be received not later than first post, Thursday, September 23rd.)

ANSWERS TO No. 1,458.

I am attending to a continuous-current electric crane designed to lift 30 tons. The figures on the name-plate of the hoisting motor (which is series wound for 400 volts) are worn off. I should be glad to know what its rated horse-power and its normal and overload current is likely to be.—(H. T.)

[A lifting speed agreeing with usual practice may be assumed.—ED., E.E.]

The first award (10s.) is given to W. H. for the following reply:—

The brake horse-power of the hoisting motor of a 30-ton crane is practically dependent on the hoisting speed. Older practice usually gives a hoisting speed of about 6 ft. per minute maximum when lifting the full 30 tons. More modern practice results in considerably higher hoisting speeds, usually about 9 or 10 ft. per minute, while for special cranes in steel works, &c., the lifting speed may be as high as 15 ft. per minute. The average efficiency overall of the gearing and ropes would be in the neighbourhood of 64 per cent. We have now all the necessary information to determine the brake horse-power of the hoisting motor. This will be given by the formula:—

$$\text{B.H.P.} = \frac{\text{lbs. hoisted} \times \text{speed of lift in ft. per min.}}{\text{Efficiency} \times 33,000}$$

$$= \frac{30 \times 2,240 \times 10}{0.64 \times 33,000} = 32.$$

This gives the brake horse-power required for a hoisting speed of 10 ft. per minute. For other hoisting speeds the horse-power may be obtained from Fig. 1.

Ordinary crane motors are usually what is known as "half-hour" rated, i.e., they will develop their full load output for a period of half an hour without exceeding certain specified temperature rises, generally 40° C. or 50° C. Another way of

rating is to say the machines will develop their full load for two minutes in every ten minutes or some equivalent rating.

A well-designed crane motor should have a maximum overload capacity of 100 per cent. in current. In this case the voltage

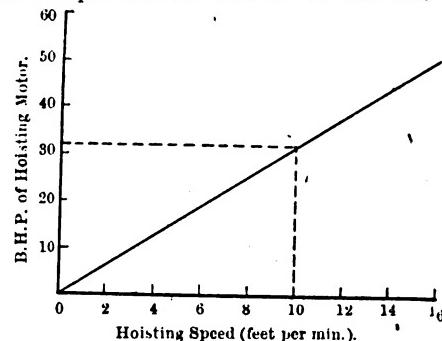

FIG. 1.—HORSE-POWER REQUIRED.

being 400 v., the normal current would be 68 amperes, corresponding to an output of 32 B.H.P. The maximum current would therefore be 136 amperes, and this for a series-wound motor would correspond to a torque of about 2½ times full load

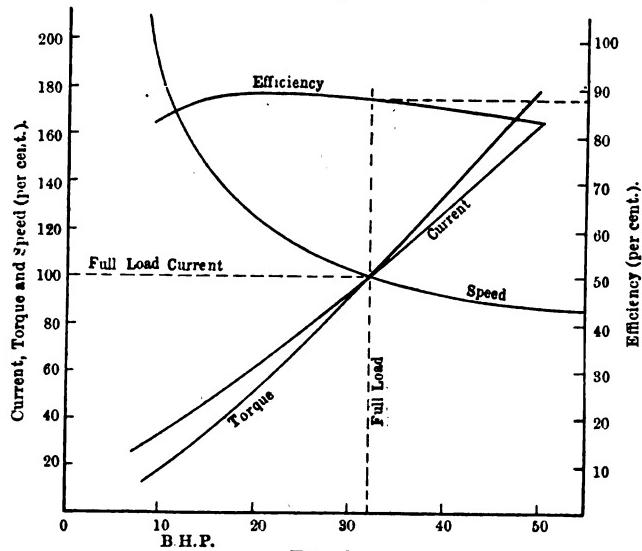

FIG. 2.

torque. This current could only be sustained for a very short time, say a few seconds.

For convenience Fig. 2 has been plotted, showing representative curves giving current, torque, speed, and efficiency as percentages of normal full load values for a 32 B.H.P. motor.

The second award (5s.) is given to "Alpha," who writes as follows:—

The rating of the hoisting motor of a crane is given by:—

$$\text{Tons lifted} \times 2,240 \times \text{ft. per minute}$$

$$\text{H.P.} = \frac{33,000 \times E}{15 \times 746}$$

where E is the efficiency of the gearing. As the crane in question is apparently an old one, the lifting speed is not likely to be high, and may be assumed to be 5 ft. per minute. Allowing about 70 per cent. for the efficiency of the gear, a 15-h.p. motor is required, and this is quite a likely figure for the lifting motor of a 30-ton three-motor crane. It would be an easy matter for H.T. to check the lifting speed, but this should be done when lifting approximately full load, as the speed of a series-wound motor varies greatly with the load.

Allowing for a motor efficiency of 80 per cent., the full load current of a 15-h.p. 400-volt motor will be $\frac{15 \times 746}{400 \times 0.8} = 35$ amps.

The motor will probably have been built for a half-hour or one-hour rating, with a permissible overload of 100 per cent. momentarily, or, say, 75 amps., allowing for the drop in efficiency on overload. If the hoisting speed is more than 5 ft. per minute, the above values of horse-power and current should be increased in proportion. It may be mentioned that it is common practice for the longitudinal travel motor of a three-motor crane to be a duplicate of the hoisting motor, though this is not invariably the case. It would be easy to determine whether they were the same size in this case, and if so the name-plate of the travel motor would, if readable, afford a check on the calculated power of the hoist motor. Alternatively, an ammeter might be temporarily connected in to measure the current when lifting 30 tons. It should be noted that a test at, say, half-load (15 tons) would give more than half the full load amps., since the hoisting speed would be higher than at full load, and the losses in the gearing would also be more than half the full load losses.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 9th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

252/14. Wireless Relays. G. VON AROO and A. MEISSNER. A relay for A.C. particularly suitable for wireless telegraphy and telephony, employing a bulb containing an ionised gas path in which the current, strengthened by the relay, is led with unchanged frequency directly or indirectly to the primary circuit of the relay again, so that the whole of the current or a part thereof repeatedly passes through the relay and is further strengthened. (Six figures.)

18,887/14. A.C. Motors. F. C. CREEDY. A variable-pole machine in which the number of poles is changed by altering the phase difference between zones or bands of current of fixed position. The method of phase variation consists in the use of a polyphase supply of such phase number, preferably prime to all the number of pole pairs, as to permit of the phase difference between adjacent zones supplied from different phases on n pole pairs being made n times the phase difference for one pole pair. (25 figures.)

20,959/14. H.T. Windings. W. H. WILSON and F. W. WRIGHT. A method of constructing high-tension windings from flat ribbon conductors wound in conical layers separated by insulating fabric. (Three figures.)

21,389/14. X-Ray Tubes. B.T.-H. Co. (G.E. Co., U.S.A.). Tubes in which overheating of the target is prevented by making the target revolve by magnetic means in order continually to present a fresh surface.

21,798/14. Locking Lampholders. C. G. M. BENNETT and C. H. JEFFCOAT. The cap of the lampholder is provided with a recess adapted to receive the screwed end of a locking pin, which is screwed into engagement with the top of the cap of the lamp to prevent it being pushed in to disengage. (Four figures.) [See ELECTRICAL ENGINEERING, Feb. 11th, p. 62.]

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: B.T.-H. Co. (G.E. Co., U.S.A.) [Distribution systems] 18,971/14.

DYNAMOS, MOTORS, AND TRANSFORMERS: SIGNAL GES. [Submersible motors] 7,821/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Cooling of dynamos] 21,825/14.

Heating and Cooking: BERRY [Heating apparatus] 17,328 and

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Before Section G (Engineering) of the British Association Meeting in Manchester on Friday, three Papers relating to wireless telegraphy were read.

Oscillations in Coupled Circuits.

The first Paper on the above subject was by Dr. W. Eccles and Mr. A. J. Makower. In this Paper mathematical investigations are detailed into the properties of circuits coupled both electrically and magnetically in a variety of ways that might give rise to single-frequency oscillations. The calculations are carried out in terms of the inductances and capacities of the circuits rather than in terms of the coupling coefficients. Although in some cases both methods of notation lead to the same results with equal ease, there are others in which the definition of the coupling coefficient becomes a matter of some difficulty. It was generally agreed that the Paper was too mathematical to be discussed in the usual way. Prof. G. W. O. Howe, who has done some work on the same lines, made a few comments, and Prof. E. W. Marchant said that the formulæ given would be of great value to the designers of wireless telegraphy stations.

Capacity of Aerials.

Prof. G. W. O. Howe then read a Paper on the capacity of aerials of the umbrella type. In a previous Paper he had

17,329/14; B.T.-H. Co. (G.E. Co., U.S.A.) [Electric heating for metal working] 19,942/14.

Ignition: KELLER DORIAN [Magnetas] 23,628/14; KING [Spark-plug tester] 24,428/14.

Storage Batteries: FULLER, FULLER, and FULLER [Accumulators] 23,182/14.

Switchgear, Fuses, and Fittings: PERRY [Conduit joints] 19,121/14; NYBORG [Switches] 19,290/14; IGRANIC ELECTRIC CO. (Cutter Hammer Mfg. Co.) [Controllers] 3,284/14; R. BOSCH [Switches] 8,180/14.

Telephony and Telegraphy: MUSSO [Transmission of impulses over circuits of high capacity] 17,246/14; JUDD, DAVIES, and EASTERN TELEGRAPH CO. [Telegraphy] 19,483/14.

Traction: THOMPSON [Communication with trains] 19,123/14; STORJOHANN [Track brakes] 19,238/14; CUMMING [Points, &c.] 21,575/14.

Miscellaneous: OESTERREICHISCHE SIEMENS-SCHUCKERTWERKE and REGAL PATENTE GES. [Electric jacquard card-punching machines] 12,673/14; GRAHAM and RICKETS [Order signals] 58/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electrochemistry: NELSON [Electrolysis] 10,604 and 10,605/15.

Telegraphy: RAINES [Multiplex wiring] 10,983/15.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

18,652/01. Blow-out Coils. T. VON ZWEIGBERGK. An improved form of magnetic blow-out attachment for controllers consisting essentially of an electromagnet enclosed by a metallic shield, against the exterior surface of which the arc is blown.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS AND TRANSFORMERS: B.T.-H. Co. (G.E. Co., U.S.A.) [Control of single-phase motors] 11,930/04; A.E.G. [Control of single-phase motors] 12,090/07; F. KLINGELFUSS [Testing transformers] 11,299/08.

Electrochemistry and Electrometallurgy: S. COWPER-COLES [Electrodes] 12,469/09.

Heating and Cooking: A. F. BERRY [Inductive heating apparatus] 12,333/06; M. HANKIN [Heating resistances] 11,128/08.

Telephony and Telegraphy: F. RITCHIE [Telautographs] 11,957/06.

Traction: W. J. WILGUS and F. J. SPRAGUE [Underrunning contact rails] 12,344/06.

Miscellaneous: W. PATTERSON and C. DARAH [Electric relighting of miners' lamps] 12,144/02; W. D. WHYTE [Magnetic compasses] 11,807/04; P. H. THOMAS [Vapour electric apparatus] 10,653/05.

developed a method of calculating the capacity of antennæ. The umbrella type, however, was not specially considered, and curves and formulæ are now given for this type. The whole aerial is assumed to have a uniformly distributed charge, and the average potential of the whole aerial under this fictitious condition is then calculated. It is assumed that if the total charge, while remaining unchanged in quantity, be allowed to have its own natural distribution, it will assume a uniform potential approximately equal to this fictitious average potential. The proximity of the earth is taken into account by the method of images. Tables and curves are given for aerials with from two to six ribs and for various angles between the ribs and the vertical. With these curves and those given in the original Paper, each of the nine component potentials of any given aerial of the umbrella type can be read off and the resultant average potential determined. The method is then applied to two practical examples, one a simple aerial with six single-wire ribs and the other a more complicated case in which each of the five ribs consists of a four-wire cage, the size of the wire being different from that used for the central vertical wire.

Earth Resistance.

The final Paper of the series was a note on "earth resistance," by Prof. E. W. Marchant. This Paper described a new method of expressing the effectiveness of earthing arrangements such as are employed for lightning-conductors, radio-telegraphic stations, and in connection with many electric power distributing systems. The method consists in determining the length of the column of earthy material which, with a cross-section equal to the surface of the earth-plates, would have the same resistance as the actual "earth." For a hemisphere embedded with its flat surface level with the surface of the ground, this

"equivalent length of earth" is easily seen to be equal to the radius of the hemisphere. Some tests were described, made by the author at Liverpool on three "earths" of different types, one being the water-pipe system of the building. Prof. G. W. O. Howe, in the discussion, said he had also done some work in this connection, and the results, which would be published shortly, indicated that Prof. Marchant's measured results were absolutely at the mercy of the specific resistance. Dr. W. H. Eccles said that in the calculation or measurement of earth resistance in wireless telegraphy, it was necessary to be specially careful to remember that the effective resistance varied with the frequency. It varied by as much as 300 or 400 per cent. Mr. J. Frith asked how Prof. Marchant measured his earth's resistance. Continuous-current was not reliable, and A.C. with a bridge and telephone was the best method. Prof. Kapp remarked that even with A.C. there was such an effect as contact resistance between the plate and the earth. The first quarter-inch contact between the plate and earth must have a different resistance to the middle of the plate and earth. Had that fact been observed and accounted for? Prof. Marchant, replying, said the main object he had in mind was to attempt to establish some sort of a standard by which the effectiveness of different forms of earth-plate could be measured. As to Dr. Eccles's point, he understood that the form of earth-plate did not make much difference. Dr. Eccles interposed that the form of earth-plate did not matter so long as it contained one-half or one-third the copper in the antenna. Prof. Marchant, continuing, in reply to Mr. Frith, said he measured with direct current. It was rather difficult to answer Prof. Kapp's point with regard to contact resistance. The results seemed to show that the main factor in the measurements was the resistance of the material.

The Research Committee.

The report of the Radiotelegraphic Investigation Committee was presented to Section A (Mathematical and Physical Science), and states that work of collection of statistical data was discontinued at the outbreak of the war after the work had been going on for only three weeks. The special observations in connection with the solar eclipse were likewise almost entirely abandoned. Some general conclusions are drawn from the few weeks' observations that were made. With regard to diurnal variations, it was seen that the strays heard in the dark hours are much more numerous and louder than those heard during daylight. Unless local weather conditions are producing great disturbance, the change from night to day conditions, and vice versa, in stations north of the equator lags behind the sunrise and sunset. The strays are more serious, especially in the daytime, in the tropics than the temperate latitudes. Excessive disturbances or "X storms" usually occur within the same two or three days over very wide areas. Occasionally they are reported simultaneously hundreds of miles apart, but more usually are separated by several hours. Periods of severe strays coincide with low and rapidly varying barometers, high wind, rapid change of temperature, and rain, and are often associated with thunderstorms not far distant. The period of greatest disturbance in the Mediterranean is September and October, the months of cyclonic weather. There appears to be two kinds of X storms occurring in the daytime, those produced by convective conditions in the atmosphere within a hundred miles of the station and those originating at a distance. No connection between strays and auroral displays has yet been traced, nor have the observations made so far revealed the 27-day period of magnetic variations.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Wakefield.—A loan of £1,000 is to be applied for to provide an additional boiler-feed pump and cooling tower.

Worcester.—An expenditure of £250 is contemplated on mains to supply the Severn Bank Tannery.

Wiring

Weston-Super-Mare.—Free Library. Town Clerk.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Lincoln.—Labour Exchange. H.M. Office of Works, Storey's Gate, London.

Nottingham.—Two large factories. Town Clerk.

Miscellaneous

Burton-on-Trent.—At a L.G.B. inquiry last week concerning powers to run omnibuses by the Corporation, the Borough Electrical Engineer said he favoured electric omni-

buses. He estimated the expenditure upon one bus at £1,200 against £6,000 per mile in the case of tramways. He put a life of ten years upon the vehicle, and added that whereas in one town he knew of the cost of petrol for one car annually was £500, the cost of electricity for a similar service would only be £365.

Edinburgh.—Six months' supply of electrical fittings for the Midlothian and Peebles District Asylum, Rosslynlee. Clerk, 19 Heriot Row.

Liverpool.—Six months' supply of electrical stores for the West Derby Union. Clerk, Brougham Terrace.

London: *Bombay Railway Co.*—Lamps and lamp fittings. Secretary, 110 Bishopsgate, E.C. Sept. 21st.

H.M. Office of Works.—Tenders are required for the repair of incandescent electric lamps. H.M. Office of Works, Storey's Gate, S.W. Oct. 1st. (See advertisement on another page.)

Manchester.—Electric lamps for the Guardians. Clerk, Guardians' Offices, All Saints'. Sept. 21st.

Merthyr Tydfil.—Six months' supply of electrical accessories for the Guardians. Clerk, 134 High Street.

Wolverhampton.—Six months' supply of electrical fittings for the Union. Clerk, Poor Law Offices. Sept. 21st.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

London: *G.P.O.*—The tender of Siemens Bros. Dynamo Works, Ltd., has been accepted for the supply of Wotan lamps during the next six months. The Postmaster-General has placed a contract for Royal Ediswan Drawn Wire Lamps.

The General Electric Co., Ltd., advises us that it has, for the seventh time, received the sixth monthly contract from the General Post Office for the supply of Osram Drawn Wire Lamps. The Company has also received contracts for the supply of many thousands of Osram and Robertson lamps to the Admiralty and the War Office.

APPOINTMENTS AND PERSONAL NOTES

Mr. J. C. White, of the St. Helen's Cable & Rubber Co., Warrington, was operated on last week for appendicitis, but is now progressing satisfactorily. He is particularly identified with the design of the company's corrosion-proof cable fittings.

Consequent upon the resignation of Mr. A. E. Wilson, the Bristol Deputy City Electrical Engineer, on his appointment to the position of Electrical Engineer to the Chief Engineer of the Southern Command, Mr. A. J. Newman, who has been in the Department for eleven years, is to be promoted to succeed Mr. Wilson. The salary will be £350, rising to £400 per annum. Mr. A. J. Ostler is to be promoted to Sub-station Engineer at £200, rising to £250 per annum, and Mr. I. A. D. Pedler is to be promoted to Mains Engineer at £175, rising to £250 per annum. The Electricity Committee also propose to appoint a boiler-house superintendent, in order to bring about further economies in steam raising, at a salary of £200 per annum.

Mr. J. F. Murdock, of the Lancashire Electric Power Co., has been appointed Borough Electrical Engineer at Bacup.

H.M. Dockyard, Rosyth, require good jointers for work chiefly in H.M. ships. See an advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. Geo. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £84 to £85 (last week £82 to £83).

Advance of Prices.—The General Electric Co., Ltd., an-

nounce an advance of 25 per cent. on the prices of conduit accessories and 10 per cent. on girder clips. Special prices will be quoted on application for casing and capping, zinc bell tubing, and galvanised material.

Electro Galvanising.—The Cowper-Coles Galvanising Co., 1 French Street, Sunbury-on-Thames, have erected a special plant for the rapid galvanising of nails and small steel and iron articles generally. They claim that a particularly even distribution of zinc is obtained.

Bankruptcy.—At the public examination of Herbert Page, Electrical Engineer, 63 Queen Victoria Street, E.C., the statement of affairs showed gross liabilities amounting to £2,278 and net assets of only £90. The debtor has been in business with a partner under the style of Smeeton & Page, with a capital of £150, but in 1904 the partnership was dissolved, and he took over the assets and liabilities. In 1907 an arrangement was made with his creditors by which 3s. 6d. in the £1 on liabilities amounting to £1,500 was paid, but in 1912 a further shortness of capital necessitated additional borrowings, and being pressed by creditors has been obliged to file his petition. The matter remains in the hands of the Official Receiver.

LOCAL NOTES

Aberdeen: *Position of Electricity Undertaking.*—In presenting the annual accounts for 1914-15 at the last meeting of the Corporation, the Convenor of the Electricity Committee said that the war has had a considerable effect upon the electrical undertaking in many ways. Fifty-seven per cent. of the men employed between 18 and 40 had joined the forces, and the shutting-down of practically all public lighting, together with the curtailing of shop-window lighting, had resulted in a drop of £3,800 in revenue. The units sold were 800,000 more than in the previous year, whilst the total working expenses were reduced by £1,027 as the result of their new generating plant and the better load factor. The large increase in the power units and the profit from them he contended justified the Committee's policy as against the critics who argued that the power tariff in Aberdeen would lead the Department to financial trouble.

Dublin: *Wiremen's Strike.*—The Dublin wiremen came out on strike on Saturday in connection with their demand for an increase of wages from 9½d. to 11d. The employers point out that this, on a normal week's work, will represent an increase of 7s. 6d. per week, and that contracts will not stand such an increase. On the other hand, the men point to the increase in the cost of living, and seem to hope that the shortness of men will also assist their cause. None of the Corporation employees, however, are affected.

Dundalk: *Power Station Extension.*—At the last meeting of the Urban Council it was reported by Mr. Spalding, the Electrical Engineer, that the new storage battery at the power station is nearing completion. The six new cells erected recently as an extension of the battery were permanently connected last week. The first of the two new Diesel engines is about to be received from the makers.

Edinburgh: *Coal Prices.*—It is stated that the Electricity Committee has had under consideration the question of giving notice to their coal contractors for a reduction in the price of coal in accordance with the terms of the recent Act of Parliament. It was decided to inform the coal contractors that the Committee expect their coal to be supplied at a price not exceeding 4s. per ton more than the corresponding prices last year.

Hove: *Increase in Electricity Charges.*—The Electricity Committee recommends that the charge for private house lighting be increased by 1d. per unit. Some objection has been taken, but the Committee is convinced that there is no alternative, having regard to the increase in the price of coal, wages, etc. The charge will now be 6½d. per unit.

At the time the Corporation took over the Hove Company there were anticipations of a decrease of 2d. per unit.

Ireland: *The Lough Erne Electricity Scheme.*—With regard to the scheme for utilising the falls of Lough Erne, of which we gave particulars in our issue for May 13th, p. 207, the *Times* last week stated that the Company which had the matter in hand will be seeking Parliamentary powers next session. It is also stated that the necessary capital has already been subscribed.

London: *St. Pancras: Allocation of Electricity Profits.*—The Electricity Committee has been considering the question of the disposal of the electricity profits for the year to March 31st, 1915. In the accounts recently presented to the Council, there was a balance of £6,413 in the net revenue account after retaining £4,000 as working balance, and the Electricity Committee now state that they have no hesitation in recommending that this sum of £6,413 should be allocated to relief of rates.

Wakefield: *Insurance against Aircraft.*—The Electricity Works are to be insured against damage by aircraft to the amount of £50,000. There was a loss of £336 on the past year's working of the electrical undertaking against a profit of £488 in the previous twelve months, and an increase in the charge for power and lighting of 2½ per cent. is to be made. This, however, will only bring the charges to the same as they were before April last.

Walsall: *The New Electricity Works.*—At the last meeting of the Council it was stated that the new electricity works will not be in operation this year as had been anticipated, and the Chairman of the Committee hoped that the public will economise in the use of electricity between 4 and 6 p.m. during the winter, this being the time of maximum demand.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Nairobi Electric Power & Lighting Co.—The directors in their annual report said that the schemes for the utilisation of the Thika Falls, forecasted in the last report and for which tenders were received and necessary financial arrangements made, had to be stopped owing to the outbreak of war. The Treasury prohibition of new capital issues being most stringently applied when it is a question of using the money outside the United Kingdom had also effectively stopped their schemes. Sanction, however, had been obtained for the issue of capital necessary to provide auxiliary steam plant at Nairobi to prevent the inconvenience which would arise by the complete stoppage of the developments of the Company's undertaking.

British Insulated & Helsby Cables.—An interim dividend of 5 per cent. is recommended on the ordinary shares, compared with 4 per cent. last year.

The Electric Vehicle.—The September number of the journal of the Electric Vehicle Committee contains several illustrations of vehicles which took part in the parade during the I.M.E.A. Convention and notes on Mr. Aytoun's Paper and the discussion on the same afternoon. Extracts are also given from a report of a Sheffield Sub-Committee in favour of electric vehicles for house-refuse collection. Other subjects treated are small industrial trucks, such as are rapidly coming into use for railway and warehouse work, and the electric taxi-cab service of Amsterdam. The list of electric vehicles in use or on order in Great Britain now reaches the total of well over 400. A supplement gives a useful series of notes issued by the Electric Vehicle Committee for the guidance of persons who wish to make arrangements for charging electric vehicle batteries. The most suitable methods to be adopted for all the usual voltages and systems of supply are set forth, and a specification of the equipment required for the actual charging board is given.

The British Westinghouse Employees' War Relief Fund.—From a statement of accounts of this fund, it appears that the total contributed to August 31st last amounted to £14,624 10s. 11d.; £10,134 has been contributed by the employees and £4,491 by the Company, and out of this sum £8,598 has been paid to dependants, £2,500 set aside for a Widows' and Orphans' Fund, over £1,200 has been spent in donations to outside funds, Christmas gifts, 1914, and payments to Red Cross workers. The number of families receiving relief is 621, and the number of employees who have joined the King's Forces 1,572. The very considerable amount of work involved in administering the funds has been performed by members of the Company's workmen and staff, voluntarily and without expense to the fund.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

SUMMARY

THE Engineering Standards Committee has issued a revised specification of electric supply meters (p. 386).

REVIEWS of technical books appear on page 386.

THE electrical equipment of the suburban lines of the London and South Western Railway is practically complete. An illustrated description of the power station at Wimbledon, the sub-stations, and the feeder system is given in this issue (p. 387).

A SMALL gas engine-driven station with some interesting details has been opened at Stowmarket (p. 388).

AMONG the subjects of specifications published at the Patent Office last Thursday are long distance telephony, conduit joints, cable telegraphy, and traction motor ventilation (p. 389).

A QUESTION relating to telephone installations in mines is propounded in our "Questions and Answers" columns (p. 389).

A PORTABLE X-ray apparatus and an electrical fire pump are described (p. 390).

NEW plant is to be installed at Sheffield (£100,000); and Aldershot (£6,194).—Cable is required at Swindon; generating plant at Pietermaritzburg (S.A.); and arrangements are to be made by the Islington Guardians for taking a supply from the Council (p. 391).

THE bulk of the electrical wiremen who came out on strike in Dublin have left the city for munitions work.—The Harrogate Borough Electrical Engineer

recommends a rateable value tariff with a secondary charge of 1d. per unit for 100 per cent. load factor apparatus.—The price of coal in Peterborough is now 21s. 4½d. per ton compared with 8s. 7d. a few years ago.—Complaint has been made in the Keighley Council at the policy of the Electricity Department in continuing to connect up new consumers (p. 392).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS FOR WEEK COMMENCING SEPTEMBER 27TH, 1915,
by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Drills, 6.30 to 7.30; 7.30 to 8.30.

Monday, September 27th: Section I., technical. Section III., squad, signalling class.

Tuesday, September 28th: Section II., technical. Section IV., shooting.

Thursday, September 30th: Section III., technical. Section I., shooting.

Friday, October 1st: Section IV., technical. Section II., squad, signalling class.

Saturday, October 2nd: Company parade, 2.30 p.m. Route march.

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

A PROSPECTUS from the Manchester Municipal School of Technology gives full particulars of the part time courses which are held there in electric and other branches of Engineering for the benefit of those whose ordinary employment occupies the greater part of their time, in connection with a scheme of certificates and associateships. These courses commence on Sept. 27th, and intending students should be enrolled during the previous week. There are special courses in wireless telegraphy, Post Office work (telegraphy and telephony), wiring, electric traction, and instrument making. A full syllabus is contained in the prospectus.

A new prospectus containing the announcements for the session 1915-16 has been issued by the Northampton Polytechnic Institute (Clerkenwell). Full particulars are contained of the day and evening courses in electrical engineering and other subjects, which include special sections on wireless telegraphy and on electrochemistry. The classes for the day courses commence on October 4th, and the evening courses on September 27th. Enrolments have already commenced. In spite of the war, some additions have been made to the laboratory equipment, and practically all the courses are announced as usual, although certain special lectures have had to be abandoned.

Killed in Action.—We regret to announce that Second-Lieut. Raymond Lodge, of the South Lancashire Regiment, the youngest son of Sir Oliver Lodge, has died of wounds received whilst fighting in Flanders. Lieut. Lodge, who joined the Forces immediately on the outbreak of war, was connected with the firm of Lodge Bros., the electrical apparatus manufacturers, the partners in which were his elder brothers.

THE STANDARDISATION OF METERS

THE Engineering Standards Committee has now issued the revised edition of the British Standard Specification for Electricity Meters (excluding electrolytic meters). This is practically a new specification, as the committee found it necessary to redraft it entirely, and to extend it considerably in consequence of the large increase, during recent years, in the size of individual installations, arising from the extension of the use of electrical energy supplied from central stations. The first edition referred only to consumers' meters of sizes up to 100 amperes, but the revised report includes provision for meters up to the very largest sizes in use, as well as for three-wire and three-phase meters.

It is important to note that this specification is intended to apply to the purchase of new meters, governing their sale by the manufacturer to the purchaser, and has no direct bearing on any questions which may arise between the supply undertakers and their consumers in connection with such of the meters as are employed to register energy supplied from public supply mains. The requirements have, however, been so drawn up that meters conforming to them may reasonably be expected to fulfil the conditions imposed by the Board of Trade on meters used in connection with public supply undertakings, and to satisfy inspectors under the Electric Lighting Acts during a considerable period after the meters have been put into service.

Certain modifications and additions have been made to the standards and definitions, and the standard sizes of meters include sizes for currents up to 5,000 amperes. The registering mechanism is dealt with at some length, and the terms used to distinguish the different types of counting mechanism are "pointer type" for the ordinary clock-face with a rotating pointer and "counter type" for the so-called cyclometer mechanisms. In the latter case it is specified that the figures shall spring quickly into position, except the lowest figure used. The term "register" is used and defined as follows:—"The term register denotes the circular scales and pointers, or the figure openings and figure wheels, as the case may be, from which are read the figures that permit evaluation of the supply to the consumer."

The limits of error are specified in a table, the formula used in the first edition of this specification having been discarded. Up to 1·25 kw. the permissible limit of error is ± 2 per cent. from full load down to one-tenth load, and ± 5 per cent. at one-twentieth load. Above 1·25 kw. the figure is ± 2 per cent. in both cases. A variation of 10 per cent. above and below the marked pressure at any load down to one-tenth is not to cause a variation in accuracy of more than 1 per cent. Excess currents of 25 per cent. for half an hour and 30 times full load for half a second, and excess voltage up to 65 per cent., are not to impair the accuracy permanently.

Meters are required to have the testing constant plainly marked, and this constant is specified as the number of revolutions per minute which the rotor should make at the full load of the meter under standard temperature conditions. Clauses have been added dealing, amongst other things, with internal and external shunts and resistances; pressure and current transformers, and the marking of the terminals of three-phase meters. Appendices have been added dealing with the precautions to be taken in the erection of meters, and notes on the testing of meters. Illustrations of typical arrangements of meter registers have also been added.

The report, the price of which is 7s. 9d. post free, may be obtained direct from the offices of the Committee (28 Victoria Street, Westminster, S.W.), and is published for the Committee by Messrs. Crosby Lockwood & Son (7 Stationers' Hall Court, E.C.).

NEW PUBLICATIONS

"The Wireless Telegraphist's Pocket Book of Notes, Formulae, and Calculations." By J. A. Fleming, F.R.S. 347 pp. 7½ in. by 4½ in. 38 figures. (London : Wireless Press, Ltd.) 6s. net; abroad, 6s. 3d.

Standard Handbook for Electrical Engineers. Edited by F. F. Fowle. 1,984 pp. 6½ in. by 4½ in. 1,516 figures. (New York : McGraw-Hill Book Co.; London : Hill Publishing Co., Ltd.). Fourth edition. 21s. net.

"Russian Self-taught, with Phonetic Pronunciation." By Capt. C. A. Thimm and J. Marshall. 184 pp. 7½ in. by 4½ in. (London : E. Marlborough & Co.) Fifth edition. Paper covers, 2s.; by post, 2s. 2d.; cloth, 2s. 6d.; by post, 2s. 8d.

REVIEWS OF BOOKS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

Wiring of Finished Buildings. By T. Croft. 275 pp. 8½ in. by 5½ in. 205 figures. (New York : McGraw-Hill Book Co.; London : Hill Publishing Co., Ltd.) 8s. 4d. net.

In the heavier branches of electrical engineering we know a great deal in this country about American practice. Many of our methods and apparatus are frankly based on American models, and the development of the electrical industry here has followed a course which has facilitated the blending of all that is best in British, American, and Continental ideas. In telephony the same applies to an even greater extent so far as American methods are concerned—in fact, in some cases, things that have been conceived here have awaited permanent adoption in Great Britain until they have been developed or re-invented on the other side of the Atlantic. House wiring, on the other hand, has been an exception, probably because it is particularly dependent on local conditions. That part of the subject which is based on Ohm's law is obviously more or less the same all the world over, but in the methods of erecting the wires and protecting them, the design and choice of fittings, and, last but not least, the methods of business-getting, British, American, and Continental practice are widely divergent.

The book before us brings this fact out clearly; in fact, it might have been written with the sole object of explaining to the Britisher the difference between British and American practice. The first part, the "Commercial Section," describes in detail the system in vogue in the United States for attracting new consumers to the mains. There, as here, it appears that the brunt of this falls upon the supply station. Wiring is let out to contractors, but it is the supply authority who has to undertake practically the whole of the business-getting. In this the main difference between American and British methods is the better appreciation in the former of the bargain-loving propensities of the public. Over there they have no L.G.B. audit, and they have also no Electrical Contractors' Association perpetually on the look-out to prevent the central stations from infringing their territory. Woe unto the municipal electricity department which could offer "to wire any residence kitchen or residence laundry for one double socket and furnish an electric iron and a lamp for \$12," payable in twelve monthly instalments; yet the Kansas City Electric Light Co., which did this, found that approximately half of the inquiries developed into contracts for wiring the entire house, and that practically every acceptance of the \$12 offer will lead to the whole building being ultimately wired. The second part of the book is the "technical section," and is equally interesting. It describes how house-wiring is done in America, and although, in many respects, British practice must always be different, the time spent in reading it will by no means be wasted.

The Motor Manual. 266 pp. 7½ in. by 5½ in. 298 figures. (London : Temple Press, Ltd.) Eighteenth edition. 1s. 6d. net; by post, 1s. 9d.

The succeeding editions of this hand-book on everything connected with the motor-car have always been kept well abreast of modern developments, and the revision shown in the eighteenth edition is as thorough as that of its predecessors. As electrical auxiliary services are more and more employed in automobilism, the space devoted to electrical matter has progressively increased, and now we find not only the latest developments in magneto ignition fully treated with the aid of admirable illustrations, but a quantity of new matter in connection with electric car lighting, engine starting, and combined systems for these purposes. The section on coil ignition has been retained in view of a possible revival of this system where batteries are already employed for other purposes, and the other portions of the work uphold the high reputation established in previous editions.

The Light Car Manual. 208 pp. 7½ in. by 5½ in., 161 figures. (London : Temple Press, Ltd.) Second edition. Paper covers, 1s. net; by post 1s. 3d. Cloth, 1s. 6d. net; by post, 1s. 9d.

Every subject of special importance to the light car owner is treated of in this little handbook, which is on the same lines as the well-known "Motor Manual" of the same publishers. Electric ignition is treated of in a clearly written chapter, and the applications of electricity to lighting, audible signals, &c., are also briefly dealt with. The note on the management of accumulators are particularly useful.

ELECTRIC TRACTION ON THE LONDON AND SOUTH WESTERN RAILWAY

We have referred on more than one occasion to the scheme of conversion to electric traction of the suburban lines of the London and South Western Railway, which involves practically all such lines within fifteen miles of Waterloo. The work is now nearing completion, and we are able, through the courtesy of Mr. H. Jones, the Company's Electrical Engineer, and the Consulting Engineers, Messrs. Kennedy & Donkin, to give some particulars of the equipment. The lines which are now being converted are the circular route from Waterloo via Wimbledon, Kingston, Twickenham, and Richmond and back to Waterloo, the Hounslow loop line, and the Hampton Court, Claygate, and Shepperton branches. The total length of these routes is about 47 miles, equivalent to about 140 miles of single track. At a later date a further system of about 50 miles of route, the equivalent of 100 miles of single track, may be undertaken. After a careful study by the engineers of the Railway of all systems in commercial use, it was decided to adopt direct current with a pressure of 600 volts on the third rail.

The Power House.

The power-house is at Durnsford Road, Wimbledon, centrally situated from the point of view of distribution, and with facilities for obtaining condensing water from the River Wandle. It also adjoins the railway, and coal can be tipped from trucks direct into the bunkers over the boiler-house—or on to a reserve storage space with a capacity of 10,000 tons. Another feature is the use of the vacuum system for ash-removal, so that there are no conveyors of the ordinary type in the station. A special viaduct, 500 ft. long, partly of ferro-concrete, connects with the railway.

The boiler-house, 287 ft. in length, runs parallel to the turbine-house, and contains at present 16 Babcock-Wilcox boilers, each with an evaporative capacity of 20,000 lbs. per hour, in two rows. They are fitted with chain-grate stokers and Green's economisers, and deliver steam at 200 lbs. per sq. in. with a superheat of 200° F. The two chimney shafts are 230 ft. high, built on the Custodis system, and are situated at the permanent end of the building. There are in the turbine-room five main and three auxiliary generating sets, with space for a sixth main set when required. The main sets are turbo-alternators of 5,000 kw. capacity running at 1,500 r.p.m., generating at 11,000 volts 3-phase 25 cycles. The turbines are of the impulse type, supplied by Dick, Kerr & Co., each provided with a separate surface condenser, supplied by Willans & Robinson, Ltd., in the basement. Each set embodies a direct connected exciter and motor-driven fan for ventilating the alternator. The three auxiliary sets are geared D.C. turbo-generators each having an output of 400 kw. at 220 volts at 5,000/575 r.p.m. These machines supply current for auxiliary power and lighting purposes. The turbines and gearing were supplied by C. A. Parsons & Co., but the auxiliary as well as the main generators were made by Dick, Kerr & Co. The switchgear was all supplied by the British Thomson-Houston Co., Ltd. (Rugby). All the high- and low-tension switchgear is in a separate bay, which runs the whole length of the turbine-house, and the switchgear is arranged on three floors. The H.T. switchgear is of the remote control type, and is in three groups. The group

'bus-bars are connected to the main or interconnecting 'bus-bars through oil switches fitted with an automatic maximum release with a time element. Cable boxes and transformers are on the turbine-house floor, oil switches and operating mechanism on the first floor, on which is also the control room, and the bus-bars on the second or top floor. The auxiliary switchboard for the 220 volts continuous current supply is erected in the switch-room adjacent to the main control-board. A 220-volt battery is also installed for the purpose of ensuring the supply of current for control purposes. With the exception of two of the four boiler feed-pumps and one boiler sump-pump, all the pumps and auxiliary machinery throughout the power-house are motor driven. The power-house also contains one motor-driven air-compressor, and a motor-driven vacuum pump for cleaning purposes, also two exhaust steam-feed water heaters and a water treating and filtering plant.

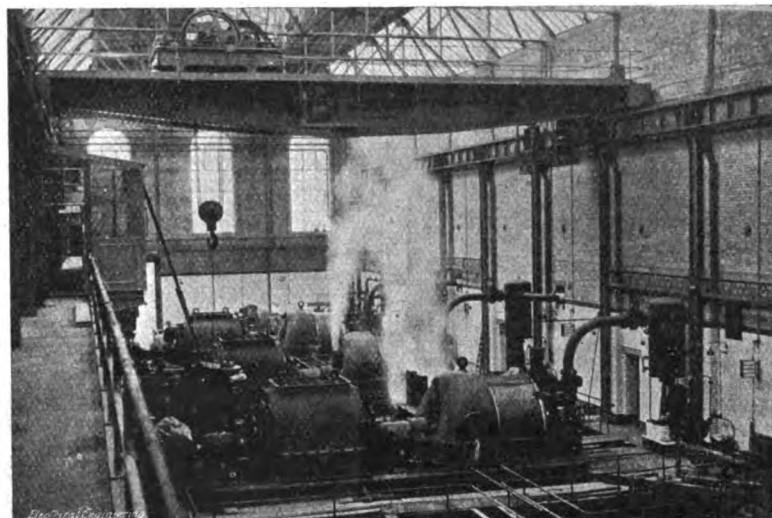

Under normal conditions the supply of circulating water will be obtained from the Wandle, and for conveying the water to and from the power-house two ferro-concrete ducts have been constructed. During periods of drought the supply from the river will be insufficient, and a part or the whole of the circulating water will be drawn from the outlet duct by means of motor-driven centrifugal pumps, and pumped over cooling towers which have been erected beside the water ducts at the end of the power-house nearest the river. The cooling towers were supplied by the Klein Engineering Co. Two motor-driven screens are provided in the inlet duct for removing leaves, weeds, and other refuse from the river water. The outer or coarse screen consists of fixed bars, cleaned by means of a motor-driven rake, and is capable of dealing with 2,000,000 gallons of water per hour.

The inner or fine screen is a rotating disc. The top of the disc is cleaned by water jets, while the bottom portion collects any fine particles or gelatinous matter that have passed through the outer screen. In flowing from the power-house back to the river, the water forms a series of cascades, and by this means it is cooled to within a few degrees of the inlet temperature before it is finally discharged into the river.

Feeders and Sub-stations.

The E.H.T. feeders to the sub-stations are 3-core, delta section, paper insulated, lead sheathed, single wire armoured, and jute served. Four sizes of cable, namely, 0·2 sq. in., 0·15 sq. in., 0·1 sq. in., and 0·06 sq. in., are used. The cables, as a general rule, are run beside the line upon hooks fixed to posts 5 ft. 6 ins. apart. Where it is necessary for them to cross the line or to run through station platforms they are laid in Howard asphalt troughing. A large proportion of the 11,000-volt feeder system is in the form of a ring main, and where duplicate cables are provided in this ring, they are fitted with protective gear consisting of balanced relays, which, in the event of a fault, isolate the length of defective cable at both ends. Duplicate cables which do not form part of the ring main are provided with balanced relays at the feeding end and balanced reversed power relays at the receiving end. Two lengths of single feeder are fitted with Merz-Price protective gear, in connection with which 3-core pilot cables have been provided. The cables were supplied by Siemens Brothers & Co., Ltd.

The 11,000-volt supply is distributed to nine sub-stations, at Waterloo, Clapham Junction, Raynes Park, Hampton Court Junction, Kingston, Sunbury, Twickenham, Isleworth, and Barnes, where it is converted to continuous current at 600 volts, at which pressure it is delivered to the track. The sub-stations contain transformers, rotary converters, and the neces-

INTERIOR OF TURBINE ROOM.

sary high- and low-tension switchgear. The rotary converters are of two sizes, viz., 1,875 and 1,250 kw., and were of the British Thomson-Houston Co.'s make; each of them is supplied from three single-phase oil-cooled transformers, manufactured by the British Electric Transformer Co. The switch-gear was supplied by the British Thomson-Houston Co. The high-tension gear is enclosed in moulded stone cells, and, with the exception that the oil switches are hand operated, is similar in construction to that installed at the power-house. Each of the continuous-current feeder panels controls two circuits, each of which have a maximum capacity of 5,000 amperes. The feeder circuit-breakers are equipped with indicating lamps which, when the breakers are open, show the position of the breaker through which the different sections of conductor rail are fed from the next sub-station.

The sub-stations, passenger stations, goods yards and sidings, between Waterloo and Clapham Junction, and on the "Kingston Roundabout" line, will take their lighting supply through a separate cable, which will also serve for supplying power in connection with the track circuit signalling arrangements. Single-phase alternating current at a pressure of 3,300 volts is supplied through this cable to static transformers placed in brick chambers at intervals along the route, current being transformed down to 220 volts. The 3,300-volt supply is obtained from frequency changer sets at the power-house and at Waterloo, Clapham Junction, Raynes Park, and Twickenham. Four of the sets consist of single-phase generators driven by 3-phase induction motors, which obtain their supply from the 11,000-volt bus-bars through transformers. To ensure reliable supply, three motor-generator sets are also provided. Two of these are at the power-house, and consist of single-phase generators direct coupled to 220-volt motors driven off the power-house auxiliary supply and storage battery. The third set is at Waterloo sub-station, and the motor driving the generator is, in this case, supplied from a 600-volt battery installed as a standby to the lighting of the terminal station. The 3,300-volt feeders are divided into sections at the transformer chambers, where they are connected to oil switches fitted with trip coils operated by relays, having operating coils connected to the copper tapes on the cables. In the event of a fault developing on a length of cable, the relays at each end of the defective length come into operation, and trip the oil switches, thus cutting out the length.

Track Equipment.

The track work involved in the electrification comprises the laying of a third rail and the bonding of the running rails of about 150 single-line miles of railway. The conductor, or third rail, is laid at one side of the track 16 ins. from gauge, and 3 ins. above rail level; it is of special high-conductivity steel, and weighs 100 lbs. per lineal yard. The resistance is approximately $6\frac{1}{2}$ times that of copper of equal volume. It is bent down at the ends to form the ramps, and is bonded at the joints with four copper bonds, having a total cross-sectional area of 1·4 sq. ins. The jumper cables connecting adjacent lengths of conductor rail at crossings and other points where it is necessary to have a gap in the rail are of 1 sq. in. sectional area, and are made up of 127 0·101 in. diameter copper wires insulated with rubber, bitumen-sheathed and braided. The return circuit is formed by the running rails, the joints of which are bonded with two copper bonds of the protected type placed under the fish-plates. These bonds are made up of copper strips, and have a total cross sectional area of 0·33 sq. in. The running rails are cross bonded at frequent intervals to equalise the current returning by the different rails. The track equipment was supplied by Siemens Bros. & Co., Ltd.

A description of the rolling stock will appear in our next issue.

ELECTRIC SUPPLY AT STOWMARKET

A NEW generating station has lately been completed at Stowmarket by the Suffolk Electricity Supply Co. to the designs of their engineer and secretary, Mr. Napier Prentice.

Two vertical four-cylinder gas engines, rated at 180 and 150 B.H.P. respectively at 250 r.p.m., have been installed, together with gas-producing plant, battery, and accessories. One interesting detail in these engines is the passing of the air supply through the crank chambers whereby the oil and moving parts are cooled. This also prevents oil leakage owing to the slight vacuum caused, while any gas escaping past the pistons is drawn off instead of being discharged into the engine-room. Some oil is, of course, drawn in with the air, but this simply drains back again from oil-separators. A view of one of these engines is seen in Fig. 1. Two air-compressors, belt-driven alternatively from one motor, are installed near the engines for charging the air-starting reservoirs to a pressure of 800 lbs. per square inch, either reservoir being available for either engine.

With the opening of the new station the voltage of supply

at Stowmarket has been raised from 100 to 200, and the dynamos, directly coupled to the engine, are wound for this pressure. The battery also has been increased to 110 cells, and it is charged and discharged through a hand-regulated Crompton booster, although regulating cells and switches are also provided for use at night and on light loads.

The gas-producers, of which there are two, together with the scrubbers, were designed by Mr. Prentice and built locally, a special feature being gilled pipes for cooling the gas immediately after production, as shown in Fig. 2. Water for the scrubbers is derived from a well, and raised by a motor-

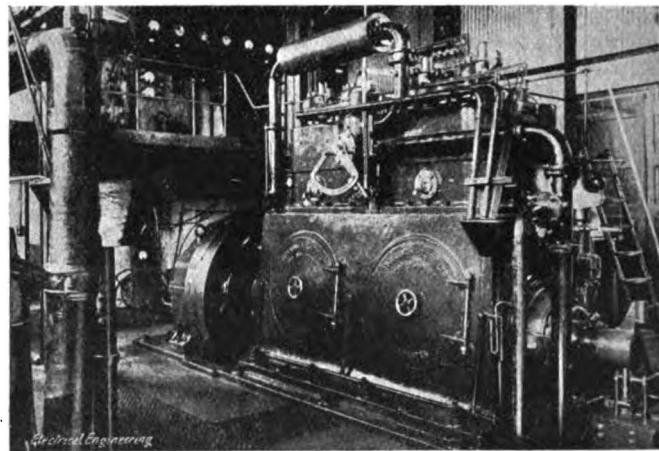

FIG. 1.—GAS-DRIVEN GENERATING SET.

driven pump into an overhead tank holding 1,000 gallons. A similar tank, mounted on the same wood framing, serves as an emergency supply for the cylinder jackets. The ordinary cooling water for the latter is circulated round a cooling tower of the Klein type by two motor-driven pumps, one of which forces the cooled water through the engines, while the other pumps from the hot-well over the tower. By discharging the engine exhausts near the top of an old boiler shell air is drawn from the engine-room through the pipe trenches. This air enters through steel screens surrounding the exhaust pipes coming down from the engines,

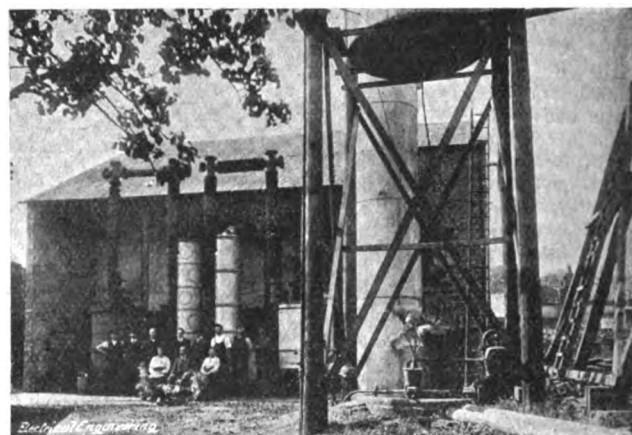

FIG. 2.—GAS-PRODUCER PLANT.

and carries off a large amount of heat which would otherwise make the engine-room very hot in the summer.

The engines were made by Messrs. Fielding & Platt (Gloucester), one dynamo by the General Electric Co., Ltd., and the other by Mather & Platt. The D.P. Battery Co. supplied the battery, while all the auxiliary motors were made by the East Anglian Engineering Co. (Stowmarket). Although the cooling tower was designed by the Klein Engineering Co. it was made locally. The new plant was all erected by the staff of the Suffolk Electricity Supply Co. under Mr. Prentice's supervision.

The New Manchester Electricity Works.—In the article on page 379 of our last issue, in which we reported Mr. S. L. Pearce's paper before the British Association upon the new Barton electricity works of the Manchester Corporation, a slight error occurs in regard to the capital charges. In the last few lines of the article we stated that the capital charges were 0·88d. per unit, whereas the context shows that the figure should obviously have been 0·088d.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 16th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

17,246/14. **Telephony.** G. MUSSO. A system for the transmission of telephone or telegraph current impulses over circuits of high capacity wherein the impulses are impressed on the main line from a local circuit, which includes an adjustable E.M.F. and an inductance so proportioned as to balance the capacity of the main line, sometimes with an adjustable condenser in series with resistance, connected in parallel with the inductance. (Four figures.)

19,121/14. **Conduits.** R. W. PERRY. Seamless conduit tubes arranged so that the lengths are connected together by screwing an external parallel thread on one end into an internal tapered thread in the enlarged end of the next section, so that a tight joint of good electrical conductivity is obtained. (Two figures.)

19,483/14. **Telegraphy.** W. JUDD, B. DAVIES, and EASTERN TELEGRAPH CO. A system of telegraphic reception intended chiefly for emergency use on cables in which signals are transmitted by impulses of opposite sign broken up at the receiving end into impulses of a frequency such as to be heard in a telephone. (Four figures.)

21,825/14. **Ventilation of Motors.** B.T.-H. CO. (G.E. CO., U.S.A.). A system of cooling particularly applicable to traction motors, in which air circulates both through and round the armature. The armature is connected at one end with the commutator through an airtight joint, and carries at the other end an enlarged head comprising a flange fitted with fan blades. (Six figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

DYNAMOS, MOTORS AND TRANSFORMERS: SHEPPARD and YARWOOD [Motor starting] 2,490/15.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,461.

In fitting up a new mine with telephone instruments between underground sub-stations and power stations and other surface buildings, what are the factors entering into the problem which require special attention? What would be the most suitable description and sizes of cable and class of apparatus and general arrangement of circuits to meet the conditions shown on the sketch? The system is to be arranged so that a person

Ignition: CONNER [Magneto contact breakers] 641/15.

Storage Batteries: MOSSAY [Battery cases] 8,189/15.

Switchgear, Fuses and Fittings: B.T.-H. CO. (G.E. CO., U.S.A.) [Connections for resistances] 23,881/14; RADLEY [Drum-type controllers] 4,748/15; STRUGE [Suspension of electrolliers] 7,510/15.

Telephony and Telegraphy: HOEGERSTAEDT and TEMPEST [High-frequency generator] 12,910/14; MARKS (Morkrum Co.) [Printing telegraphs] 19,237/14.

Traction: IRVING [Signalling] 22,986/14.

Miscellaneous: SCHWERIN [Magnetic separators] 19,313/14; TYLER and BEERLE [Connections] 19,319/14; MACKENZIE (International Electric Tool Co.) [Electromagnetic percussive devices] 19,322/14; COOKE [Contact breakers] 21,368/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Switchgear: RENAULT [Controllers] 12,267/15.

Miscellaneous: GABET [Magnetic clutches] 12,301/15.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS AND TRANSFORMERS: C. A. PARSONS and G. G. STONEY [Field windings for turbo-generators] 12,408/03.

INCANDESCENT LAMPS: B. T.-H. CO. (W. P. BURROWS, U.S.A.) [Tabulating machine] 12,416/02; W. L. WISE (Moore Electrical Co., U.S.A.) [Vacuum tube lighting] 12,582/02.

INSTRUMENTS AND METERS: G. HOOKHAM [Meters] 12,009/08.

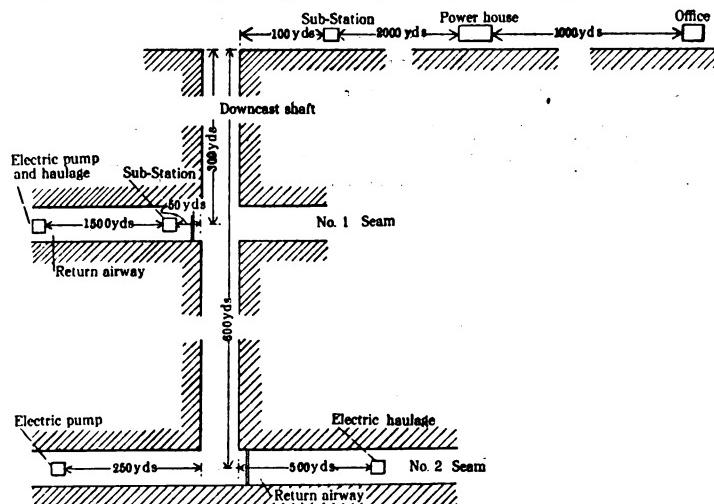

SWITCHGEAR, FUSES AND FITTINGS: ZUCKER FABRIK FRANKENTHAL [Controllers] 12,258/09.

TELEPHONY AND TELEGRAPHY: C. TURCHI [Telephone systems] 12,691/04; J. E. KINGSBURY (Western Electric Co., U.S.A.) [Telephone repeaters] 11,605 & 11,606/05 and 17,047/08.

TRACTION: M. B. CHURCH [Gearing for electric cars] 12,729/07.

MISCELLANEOUS: P. CRAMER [Indicator and regulator of the hygroscopic state of the atmosphere] 12,945/07.

could speak to the station or surface office from any other point, or could speak between any two points underground, and

must be arranged so that other points about mine can be added later.—"WORKER."

(Replies must be received not later than first post, Thursday, Sept. 30th.)

ANSWERS TO No. 1,459.

No reply worthy of an award has been received.

ANSWER TO CORRESPONDENT

"H. T."—It is impossible to say what the voltage on the crane trolley wires is. Presumably it is the same as the rest of the power supply on the premises, which is probably in the neighbourhood of 440 volts, unless only small motors are employed, when it might be about 220 volts.

"ELECTRICAL ENGINEERING" TRADE SECTION

CATALOGUES, PAMPHLETS, &c., RECEIVED

ELECTRIC POWER AND LIGHTING.—An illustrated booklet from L. E. Wilson & Co. (10 Corporation Street, Manchester), contains information as to various electric works driving, and other installations, carried out by the firm.

DIESEL ENGINES.—A leaflet from Mirrlees, Bickerton & Day (Hazel Grove, Stockport) contains a reprint of an article which appeared in a contemporary on the design of pistons and other engine parts particular from the point of view of presenting an excess of oil reaching the upper side of the piston.

THE FIREBRAND.—The Pyrene Co., Ltd. (19-21 Great Queen Street, W.C.), have issued the first number of a monthly circular with the above appropriate title, dealing with the capabilities of and results obtained by their Pyrene fire extinguisher, which employs a special liquid particularly suitable for use in case of electrical fires.

MERCURY VAPOUR LAMPS.—A pamphlet has been issued by the Westinghouse, Cooper-Hewitt Co., Ltd., 80 York Road, King's Cross, containing a reprint of an illustrated article on the artificial lighting of a moving picture studio, in which the application of mercury vapour lamps to this class of work is discussed.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

BOOKS.—A new catalogue of technical and scientific books, including a large proportion of electrical works, has been issued by the Hill Publishing Co. (6 Bouvierie Street, E.C.), agents for the McGraw-Hill Book Co., of New York.

ENGINEERS' PLANT AND TOOLS.—We have received a very comprehensive catalogue of foundry and engineers' plant and tools, &c., from Murphy, Stedman & Co., Ltd. (180 Gray's Inn Road). A considerable variety of handy appliances, machine tools, wood-working machinery, road tarring apparatus, and other contractors' plant is included, and it is important to note that the whole is of British manufacture.

ELECTRIC FIRES.—A catalogue from Ikin & Eads, Ltd. (47 to 57 Marylebone Lane, W.), gives in attractive form particulars of many designs of the "Qued" electric fire, the principal features of which were described in ELECTRICAL ENGINEERING, July 22nd, p. 316.

AN EDISWAN LAMP SHADE

A n illustration is given here of a very effective card-board shade, specially intended for showroom window lamps, which the Edison and Swan United Electric Light

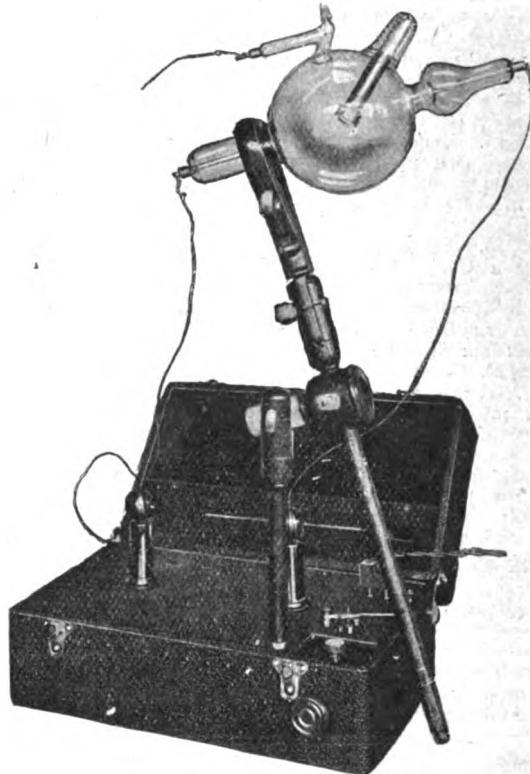

Co., Ltd. (Ponders End, Middlesex), are presenting to their trade customers free of charge.

A PORTABLE X-RAY OUTFIT

A RECENT publication of the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.) describes the "Dubilier" portable x-ray apparatus, which can easily be carried from place to place, and can be used direct on any ordinary electric light circuit, thus possessing considerable

advantages over the more cumbersome types of apparatus for x-ray work, whether for medicine, surgery, or dentistry. The pattern illustrated here, which is more particularly designed for dentists' use, employs a five-inch tube, and can work on either D.C. or A.C. at voltages from 55 to 250 volts. It is also fitted with an adjustable spark gap for use in high-frequency treatment, and attachments for cautery. The

DUBILIER PORTABLE X-RAY EQUIPMENT.

weight of the complete apparatus is 28 lbs. A larger size is also made. The apparatus is extremely simple, and there is only one switch and regulator to attend to. The current consumption is very small, and to judge by the radiographs reproduced in the catalogue, results are obtainable fully equal to those produced by larger apparatus.

AN ELECTRIC FIRE PUMP

I N the case of buildings where electric power is utilised, an electrically-driven pump is frequently adopted for fire protective purposes, and one of the most popular designs is the "Hatfield" treble-barrel type, made by Merryweather & Sons (Greenwich). Upwards of 1,000 of these pumps have been put into service. A recent example was installed in the fire station attached to a new extension of the works of the Kettering Clothing Manufacturing Society, which possesses a very efficient fire brigade.

The pump, which is electrically driven, is capable of delivering 300 galls. per min., and discharges into a 4-in. main, to which hydrants are attached. A special feature of the installation lies in the fact that automatic starting arrangements are provided, consisting of a solenoid starter controlled by relays in connection with a water-pressing indicator, so that on an outbreak of fire all that is necessary is to run out the length of hose nearest the fire and turn on a hydrant, when the pump immediately starts running. A considerable saving of time can thus be effected, as in the event of emergency there is no necessity to go near the pump. When the hydrant is closed, the electric current is automatically cut off and the pump ceases to work.

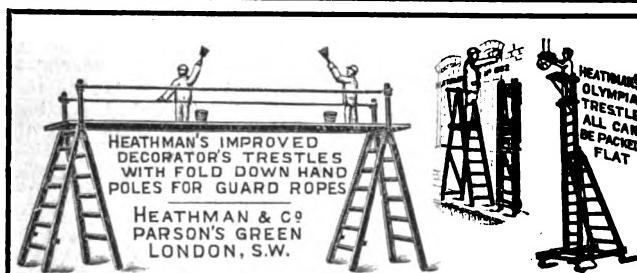

The water is supplied by two large underground tanks and four on top of the buildings, the total supply on hand being 62,000 galls. Two large branches are also taken direct from the Council's mains, one being laid on to the "Hatfield" pump, and the other to a ground hydrant with standpipe for the protection of the one-storey section of the buildings.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Aldershot.—The Council has taken up a loan of £6,194 in connection with the electrical undertaking at 4½ per cent.

Buxton.—A distributing cable at an estimated cost of £165 is to be laid.

Liverpool.—Three months' supply of electrical goods for the Toxteth Park Guardians. Clerk, 15 High Park Street, Liverpool. Sept. 25th.

London: Islington.—An expenditure of £500 is to be incurred in order to provide an alternative supply from the Corporation mains. Apparently the infirmary authorities are going to shut down their existing generating plant, as the Chairman of the Lighting Committee anticipates a saving of £2,000 by the adoption of the new scheme.

Sheffield.—Increased demands from factories working upon Government contracts have rendered it necessary to instal additional generating plant at an estimated cost of £100,000. The Ministry of Munitions has been approached in connection with the matter, and has given its consent, and also undertakes to make arrangements whereby at the close of the war the new plant shall be sold to the Corporation or dealt with in some way on fair terms to both sides should the Corporation not require to keep it.

South Africa.—H.M. Trade Commissioner at Pietermaritzburg records the need for additional generating plant in the Corporation's power station.

Swindon.—An overhead transmission line is to be erected to supply Messrs. Grundy's factory at a cost of £281.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Barnsley.—New Town Hall.

Dudley.—A number of new factories are about to be erected.

Mansfield.—Extensions to Isolation Hospital.

Nottingham.—Extensions to City Isolation Hospital. Town Clerk.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

London.—Pope's Electric Lamp Co. has received orders for several thousands of lamps, both carbon and metal filament, from the Admiralty, War Office, and H.M. Office of Works.

H.M. Office of Works.—A contract has been placed with the "Z" Electric Lamp Manufacturing Co. for a twelve months' supply of "Z" drawn-wire metal filament lamps.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £86 10s. to £87 10s. (last week, £84 to £85).

Dissolution of Partnership.—H. E. How, C. L. Arnold, and C. R. Bellings, trading as Bellings & Co., specialists in electric heating at Derby Road, Edmonton, have dissolved partnership. The business in future will be carried on by C. R. Bellings.

Change of Address.—The Fuller Electrical & Manufacturing Co. have changed their address to Canada House, Kingsway, W.C.

The Association of Mining Electrical Engineers.—The annual general meeting of the Association will be held on October 2nd at 3 p.m., at the Midland Hotel, Manchester. The meeting is entirely a business meeting, other usual arrangements having been abandoned.

APPOINTMENTS AND PERSONAL NOTES

Mr. Arthur James, who until recently was outside representative for the Record Electrical Co., Ltd., for Lancashire and Yorkshire, has now joined the board of directors of the company, and has transferred his activities to Scotland.

The Belfast Tramways and Electricity Committee requires a senior and a junior Engineer-in-Charge. The wages are £4 and £3 per week respectively. Applications to the City Electrical Engineer by Sept. 24th.

An application by Mr. R. A. Traill, Burgh Electrical Engineer at Lossiemouth, for an increase of salary has been put on one side for the moment by the Council, in view of the warnings of the L.G.B. as to the reduction of expenditure.

LOCAL NOTES

Aberdeen: *Increase in Charges.*—By the casting vote of the Convenor of the Electricity Committee, the Corporation is recommended to add 15 per cent. to all accounts of consumers in the Electricity Department.

Birmingham: *Unauthorised Electrical Installation.*—The licensee of the Aston Theatre Royal was summoned in the Birmingham Police Court last week for using an electrical installation before it had been inspected by the Electricity Department. The summons arose out of a fire which occurred at the theatre. The offence was admitted, and a fine of £5 and costs was imposed.

Brighton: *Increased Charges.*—The Corporation is recommended to increase the charge for lighting from 4½d. to 5d. per unit, and for power and heating from 1½d. to 1¼d. per unit. A local paper reflects that when times are prosperous the ratepayers share the Electrical Department's profits, but when times are hard the consumers alone have to pay.

Dublin: *The Wiremen's Strike.*—A somewhat curious, although not unexpected, position has arisen in Dublin in connection with the strike of electrical wiremen notified on page 384 of our last issue. The men have found it so easy to get employment in munition factories in Belfast, Glasgow, and in England that, according to the local newspapers, practically all the dissatisfied wiremen have migrated in this way, with the result that great difficulty is being encountered in carrying on the ordinary wiring work in Dublin.

Harrogate: *Electricity Finances.*—A discussion took place at the last meeting of the Corporation with regard to a suggestion by the Lighting Committee that all revenues of the electrical undertaking should be handled directly by the Department, instead of by the Borough Treasurer's Department as at present. On the other hand, the Finance Committee presented a recommendation that it would be inadvisable to alter the present arrangements. In support of the Electric Lighting Committee's proposal, the Chairman of the Committee pointed out that it was an advantage for the Department to get into as close touch as possible with its consumers in order that every possible use of electricity might be brought to their notice. Apparently the matter has been the cause of some little friction, as letters from Brighton, Bristol, Southampton, and elsewhere have been received in support of the proposal. Eventually, however, the proposal of the Lighting Committee was defeated by 18 votes to 10.

New Tariff.—Mr. G. Wilkinson, the Borough Electrical Engineer, recommends the adoption of a rateable value tariff on the basis of 15 per cent. plus ½d. per unit, or ¾d. per unit for any approved current-consuming device having 100 per cent. load factor with automatic control. This tariff is to apply to private residences where a reasonable amount of "other uses" apparatus is installed.

Keighley: *Complaint Against Extensions.*—At the last meeting of the Council Alderman Midgley complained that the

Electricity Department is constantly doing work without the knowledge or sanction of the Council, and incidentally he protested against the way in which the Department was alleged to be spending money at a time when the strictest economy was being urged all round. Cables, he said, were being laid to supply private users all over the town, notwithstanding the statement of the Engineer that the works could not meet the present demands. He consequently moved that a recommendation for a 40-ton crane at the electricity works at a cost of £788, and also for a centrifugal pump at a cost of £350, be referred back. The reference back was carried.

Peterborough: *Increased Charges.*—The desirability of increasing the charges for electric light and power came before the City Council at its last meeting in the form of a paragraph from the Electricity Committee that there should be an increase of ¼d. per unit. Evidently, however, the Committee did not consider this a sufficient increase, for the Chairman asked that the matter should be referred back for further consideration. It was pointed out that the Committee had a very serious position to consider, having regard to coal of a similar quality to that which was paid 8s. 7d. per ton for in 1907 now costing 21s. 4½d. per ton.

Pontypridd: *Electricity Accounts.*—There was a loss of £181 upon the electricity undertaking last year compared with a profit of £1,083 in the previous twelve months.

The Northern Universities and the War.—We have been favoured with a copy of a letter which the Vice-Chancellors of the Universities of Manchester, Liverpool, Leeds, and Sheffield have addressed to the committee appointed by the Treasury to consider the question of public retrenchment, the purpose of which is to deprecate the withdrawal of certain Government grants which are enjoyed by these institutions. Attention is drawn to the great services which these Universities have been able to render to the State, notwithstanding the depletion of their ordinary income and other disorganisation due to the war, and an excellent case is made for a continuance or even an enlargement of the Government subsidies, without which their present work and future powers would be seriously crippled.

The Gretna Railway Disaster.—In his report upon the disaster to a troop train on May 22nd near Gretna, Col. Drury, in his recommendations for the prevention of the terrible results arising from fire breaking out in wreckage after a bad collision, besides recommending that the coaches should be made of fireproof material as far as possible, emphasises the necessity for "the provision of electric lighting in all new stock, and gas lighting in existing stock to be abolished and electric lighting to be provided as opportunity admits." He remarks further that most of the principal companies are providing electric light in all new carriage stock, and some are arranging to convert existing gas-lit stock as opportunity occurs, but this must necessarily be a slow process spread over many years.

Munitions Works Dispute.—Complaints were laid at a local court of the Metropolitan Munitions Tribunal on Monday against a number of employees of a telephone manufacturing company which is engaged on war work, for breach of regulations. It was explained by Mr. Burney, the Managing Director of the Company, that in order to arrange a more complete night shift certain new hours and regulations were put into force, but the men complained of refused to conform to them. Several of them had remained away from the works for a day or two. The men, on the other hand, argued that they had not been given notice of the alterations, but the court ruled that the men had been notified in sufficient time, and seven of them were fined £1 each. Another man implicated had since returned to work, and was not fined.

A Convenient Calculator.—A new form of reckoning chart for multiplication, division, squares, cubes, &c., has been prepared by Dr. E. E. Fournier D'Albe, and is published by the Educational Supply Association, 40-44 Holborn Viaduct, E.C., at 3d. net. It depends on the use of a logarithmic scale ruled at an angle 45 degrees across similar horizontal and vertical scales. Calculations can be very rapidly checked simply by injection with an accuracy claimed to be within one per cent.

Ediswan—B.T.-H. Shooting Match.—This competition between the Ediswan Rifle Club and a team from the British Thomson-Houston Co., Ltd., resulted in a win for the Ediswan team with a total of 1,579 against 960. Messrs. E. Winterflood (Ediswan), and Redfern (B.T.-H.) were awarded silver spoons presented by the Ediswan Rifle Club for the highest scores on the two sides, and wooden spoons consoled those who made the lowest scores.

The Association of Supervising Electricians.—This Association commences its second season on Tuesday, Sept. 28th, at 8 p.m. at St. Bride's Institute. The Presidential Address will be given by Mr. A. H. Dykes. A complete programme of papers has been arranged for the ensuing season.

SUMMARY

THE effect of variation in frequency on a fan motor is discussed in our Questions and Answers columns (p. 394).

THE equipment of the electric trains for the suburban lines of the London and South Western Railway is described in an illustrated article. A control system giving automatic acceleration is employed (p. 395).

A NUMBER of books on electrical engineering and allied subjects are reviewed on pp. 396 to 398.

EXPERIMENTS are being made with some success in America in communicating with moving trains by wireless telephony (p. 398).

THE annual conference of the Municipal Tramways Association was held in London last week. A discussion upon the effect of the war upon tramway undertakings took place, but there was some divergence of opinion as to the advisability of increasing fares (p. 398).

AMONG the subjects of specifications published at the Patent Office last Thursday were lampholders, electric hammers, motor starters, and accumulator cases for motor vehicles. Opposition has been entered to two electrolytic patents and a patent for a cable-testing pressure tank expires this week after a full life of fourteen years (p. 399).

A 3,000-VOLT regulator is required at Dunedin (N.Z.); a new turbo-alternator will shortly be required at Bootle; mains extensions are contemplated at Basingstoke and Plymouth; seven 200-kw. transformers are

required at Hammersmith; a cooling tower at Pembroke (Ireland); and flame arc lamp carbons at Salford (p. 401).

A CONSIDERABLE addition has been made to the number of electrical undertakings which have increased prices. On the other hand, the Newcastle-on-Tyne Electric Supply Co. has reduced its charges for supply for heating and cooking purposes.—The Salford Corporation is now taking less electrical energy from the Lancashire Electric Power Co. in consequence of the installation of the new 5,000 kw. set.—The proposal of the Newquay Electric Light and Power Co. for an increase in the maximum price in its provisional order is meeting with strong opposition (p. 402).

A QUARTERLY dividend of 1½ per cent. is declared on the common stock of the Westinghouse Co. (p. 402).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS by Lt.-Colonel C. B. CLAY, V.D., Commandant.

Drills, 6.30 to 7.30; 7.30 to 8.30.

To-DAY, Thurs., Sept. 30th: Section III., technical. Section I., shooting.

Fri., Oct. 1st: Section IV., technical. Section II., squad, signalling class.

Sat., Oct. 2nd: Company parade, 2.30 p.m. Route march.

Mon., Oct. 4th: Section I., technical. Section IV., squad, signalling class.

Tues., Oct. 5th: Section II., technical. Section III., shooting.

Thurs., Oct. 7th: Section III., technical. Section II., shooting.

Fri., Oct. 8th: Section IV., technical. Section I., squad, signalling class.

Sat., Oct. 9th: Company parade, 2.30 p.m. Route march.

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

Arrangements have been made to share headquarters with the 4th Battalion Central London Regiment Volunteers, at Chester House, Eccleston Place (three minutes' walk from Victoria Station, Brighton Line).

Boiler Practice.—The annual memorandum issued by Mr. C. E. Stromeyer, Chief Engineer to the Manchester Steam Users' Association, contains a reprint of the Association's leaflet on Advice to Boiler Attendants, followed by comments addressed more to owners of boilers. Mr. Stromeyer discusses in detail the several items in boiler expenses, such as coal bill, repairs and renewals of boilers, stokers, feed-water heaters and economisers, and in a general summary he shows that the annual expenses for an average size boiler may, under favourable conditions and good management, be as low as £394 per annum, and as high as £700 if adverse conditions are coupled with bad management. The sources of these expenses, and the means for reducing them, are discussed in the concluding portion of the memorandum, which deals with the smoke nuisance, with burning qualities of coal, the clinkering qualities of their ashes, with the wasting of firebrick furnaces, and with grease, scale, and corrosion.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,462.

Please describe an inexpensive workshop method of varying the frequency of 60 periods 50 per cent. either up or down; expensive and elaborate arrangements out of question, as the changes are only required for testing purposes.—W. E. L."

(Replies must be received not later than first post, Thursday, Oct. 7th.)

ANSWERS TO No. 1,460.

I have a 100 volt 50~ small table fan (series wound) which will not run on a 105 volt 83~ current. Is this due to the difference of the currents, or is there a fault in the fan? A current passes, causing the fan to hum. What is the general effect of a change of voltage and change of periodicity on such a motor? Should a similar 100 volt D.C. motor run on 100 volt 50~ A.C. circuit?—K. E. N.

The first award (10s.) is given to "E.B.P." for the following reply:—

The motor could hardly be expected to run efficiently on the 83 cycle current, owing to this frequency being so much higher than that for which it has been designed, although one would not expect it to refuse to run altogether. The effect of the higher frequency would be an increased back E.M.F., with a corresponding reduction in the current taken by the motor, and consequently in the torque developed by it. There would also be an increase in the heating of the motor. Under these conditions, one would expect the motor to run considerably slower than its normal speed.

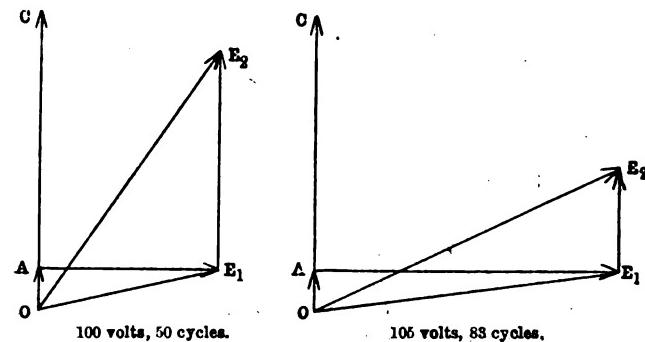

I would say that probably the motor is not really series wound, but is a repulsion motor; that is, a motor having an armature and field coils somewhat similar to a D.C. series motor, the field magnet alone being supplied with single-phase current, while the armature is not connected with the external circuit at all, but has its brushes short-circuited. If the brushes of such a motor are set in the right position it will run when supplied with single-phase current, having a characteristic curve very similar to that of a D.C. series-wound motor. By shifting the brushes the rotation can be reversed, and the proper position can be found by trial. In the present case the brushes may not be short-circuited, or they may be set in the neutral position, or the motor may be connected—wrongly—with the armature and field magnet in series. Any of these faults would prevent the motor from working, while allowing a current to pass through the machine. However, in any case, the motor will not work well on the 83 cycle circuit, its speed will be low and its heating excessive.

The effect of a change of voltage on such a motor will be a proportionate change of current, with a corresponding increase or decrease of speed. I have indicated above what the effect of

a change of periodicity would be. A 100-volt D.C. motor connected to a 100-volt 50-cycle alternating supply would in all probability run, but for similar reasons to those discussed above, at a reduced speed. Moreover, unless the field magnet were entirely built of laminations, it would get excessively hot, due to eddy currents caused by the alternating flux.

The second award (5s.) is made to H.J.E., who writes as follows:—

The table fan in question certainly ought to run on 100 volts 83 cycles, but at a lower speed than on 100 volts 50 cycles. This is obvious when one refers to the vector diagram of a series A.C. motor. In Fig. 1, let AO represent the ohmic drop in phase with the current OC , whilst E_1A represents the E.M.F. produced by the pulsating field in the stator winding. The E_1E_2 is the E.M.F. produced in the armature winding by the latter's rotation in the field flux. The resultant vector OE represents the terminal PD . Now E_1A is directly proportional to the periodicity of the supply. Consequently for the same

terminal voltage, E_1E_2 will be smaller on 83 cycles than on 50 cycles, and thus the armature is only required to run at a lower speed. In order to give as good results on 83 cycles the stator should be stripped and rewound with 60 per cent. of the existing turns per pole. If the periodicity of the supply is kept constant, the speed of the motor on a fan load is approximately proportional to the applied voltage. On the other hand if the applied PD is kept constant, the speed will be approximately inversely proportional to the periodicity of the supply.

With regard to the last part of the question, "K. E. N." is referred to the answer to Question No. 1,457, in ELECTRICAL ENGINEERING, Sept. 9th.

UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

FULL information as to the session which commenced at Armstrong College, Newcastle, last Monday is contained in the new issue of the calendar which we have just received. The courses in electrical engineering are under Prof. W. M. Thornton, assisted by Mr. W. W. Firth. Both day and evening classes are held. A special feature of the college is the Mining Department, the courses in which include instruction in mining electrical engineering. The work is being carried on uninterrupted, in spite of the fact that some of the departments are just now housed in temporary premises.

The Borough Polytechnic Institute reopened for the present session last Monday. A four years' general course in electrotechnics is given under Dr. J. Henderson, and there are also special courses in electric wiremen's work and in electrical construction and workshop drawing.

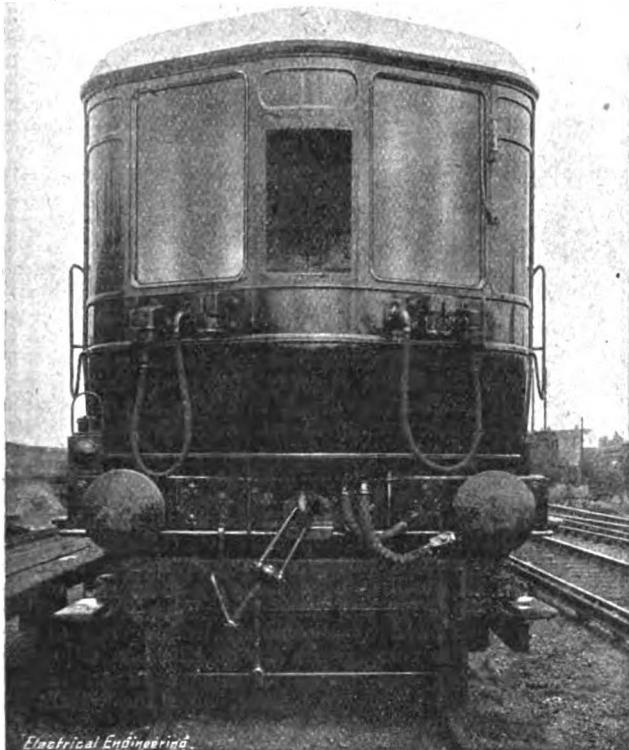

London Lighting.—Sir John Simon, in reply to a question in the House of Commons on Thursday last, said that the reduced lighting in the metropolitan area had been most carefully studied, and the scheme adopted was based on the result of repeated observations alike from the air and from the ground. The main object to be aimed at was uniformity rather than absolute darkness, and it was a matter of great importance that the scheme should be applied equally in all parts of the area, exceptional darkness being as likely to prove a distinctive mark as exceptional brightness. Private citizens and local authorities had shown themselves generally willing to accept the application of the scheme, and the lighting orders made to give effect to it, but as some cases of local departure from the scheme had come to his notice, he was proposing to make a fresh Order defining more exactly some of the requirements, as, for instance, in the matter of the lights in private houses, and giving the police increased power to enforce it.

ELECTRIC TRACTION ON THE LONDON AND SOUTH WESTERN RAILWAY

Rolling Stock

THE rolling stock consists of 252 51 ft. compartment-type coaches, until recently used in steam service and now converted for electrical working.

The trains are equipped for multiple unit working, and for convenience in handling are made up of three-coach units, consisting of two motor coaches with a trailer coach close-coupled between them. It is intended to operate these units

Electrical Engineering

FIG. 1.—FRONT OF MOTOR COACH, SHOWING CABLE COUPLINGS, &c.

as three or six-coach trains, depending upon traffic requirements.

Each three-car unit is equipped with four motors, each rated at 275 h.p. at 590 r.p.m., geared with a ratio of 21 to 59 to standard 42½-inch driving wheels. These motors are arranged in pairs on the bogies underneath the driving compartments at opposite ends of the unit. All the control gear is placed in these compartments, each pair of motors being controlled by its own set of control gear. The positions of the individual pieces of apparatus have been carefully arranged for ease of access for inspection, cleaning, and adjustment with this end in view. Access to the control apparatus is obtained on the one side from the driver's compartment and on the other through large hinged doors in the partition between the driver's and luggage compartments. The weight of this apparatus comes over the driving bogie and so increases the adhesive weight on the driving wheels. For the electric trains the original rolling stock, consisting of the usual compartment coaches with side doors has been used, the necessary alterations being made to fit them for the electrical apparatus. The appearance of the curved front of the leading coach is shown in Fig. 1.

The electric equipment was supplied by the British Westinghouse Co. The motors are of the latest series-wound totally-enclosed type, with box frames, and the bearings carried in end housings. They are equipped with commutating poles. The field poles are laminated and the interpoles are made solid and have a special shape of tip. Spring washers are used in both cases to keep the coils firm in their places and to prevent chafing due to vibration. A fan is provided on the armature for air circulation on the axial system. Air drawn through openings in the commutator spider and armature core passes through the fan and back between the field coils and over the armature and commu-

tator. Openings to the atmosphere are not provided; the whole of the cooling is done by radiation from the case, but the circulation of air ensures even temperature throughout the motor. The brush holders are substantial bronze castings, clamped to the machined face of the casting, which is supported by two insulated rods bolted to the motor frame. The insulation is of pure mica directly surrounding the rods which are forced into their place in the casting by a considerable pressure, the mica being protected during this process by hardened steel split tubes. The brushes are arranged for radial adjustment to allow for wear of the commutator and are readily accessible for inspection and adjustment through the commutator trap door. The motor casing is carried by a suspension bracket, which is supported through rubber springs from the truck transom.

The control of the trains for multiple unit working is effected by the Westinghouse Company's "All Electric" system of automatic relay control. In this system the motor current is handled by a suitable number of electrically operated contactor switches, the operating coils of which are connected to control wires running throughout the length of the train and actuated by six small master controllers. The contactors are provided with interlocking switches connected in their operating circuits to ensure the correct sequence of changes in the connections. The motor equipment on each coach is controlled during the accelerating periods by its own relay, which is independent of the other relays on the train; hence the motors on the different coaches are notched up in accordance with their individual requirements, which are, in a measure, dependent upon the diameter to which the wheels may be worn and the slight inherent differences in the characteristics of the motors. This system, therefore, helps to equalise the load on the different motor coaches. The operation of the controller is extremely simple, the driver having merely to move the controller right round to the full "on" position, and the relays automatically do the rest. Powerful magnetic blow-outs are fitted to all pieces of apparatus where there is a possibility of arcing when breaking current. The arcing tips are of hard drawn copper, which can be easily and cheaply renewed. A wiping action between the contacts is provided, so that any roughness due to arcing when opening the circuit does not interfere with the contact surface when the switch is in the closed position. Each con-

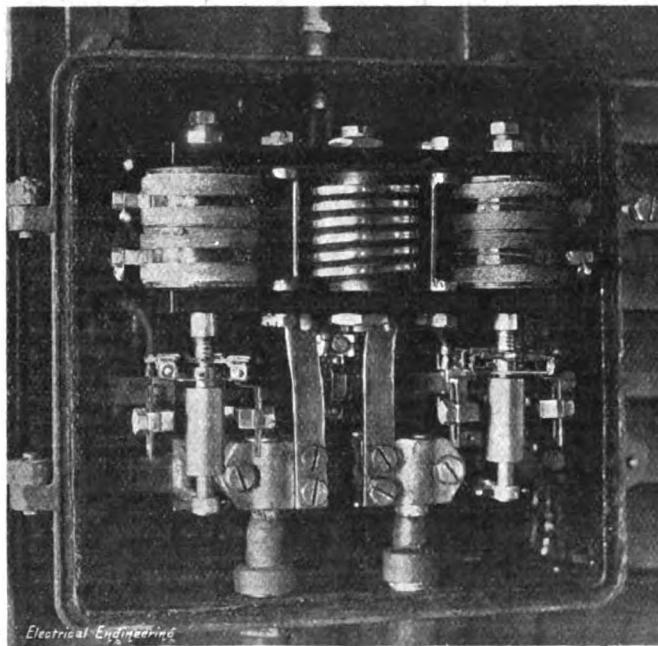

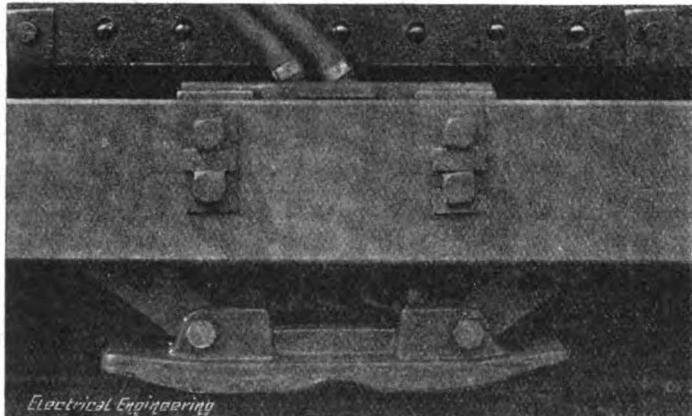

FIG. 2.—AUTOMATIC ACCELERATION RELAYS.

tactor and circuit breaker is carried by a pressed steel plate clamped to mica insulated steel tubes, which are fixed to two channel irons running the full length of the switch group. This method of construction is light and strong, and has the necessary flexibility to withstand vibration. It also renders the withdrawal and replacement of a contactor switch an extremely easy matter. The interlocking switches are fixed at the back of the contactor switches, and are operated by a lever from the movable core of the contactor solenoid, thus ensuring a definite position of the interlocking switch, corresponding with a definite position of the contactor. These

interlocking switches have been most carefully designed with a view to ready inspection, renewal and withdrawal when necessary. The smallest possible number of different parts is used in the construction. The frame carrying the contactor switches forming the motor car group lies across the width of the coach in the driving compartment. It also carries the necessary motor starting resistances and the main fuse above the contactors. The motor resistances are of the usual three-point suspension grid type, mounted on mica insulated tie bars fixed to pressed steel end frames, giving a strong and rigid construction. The circuit-breaker is similar in construction to the contactor switches. It is provided with heavy laminated brushes in addition to the contact jaws, and adjustable overload and trip coils. The reverser is of the drum type.

The master controller is provided with both main and reversing handles, so interlocked that the reversing handle must be either in the forward or reversed position before the driver can operate his controller. The main handle embodies the "dead man" feature, the arrangement being such that in the event of the driver releasing the handle the supply of control current is interrupted, thus opening all the main contactors. The brakes are automatically applied at the same time. Should the driver allow the handle to move upwards at any time, he must bring it to the "off" position again before he can release the brakes. When coasting and when making ordinary service stops the driver moves the main handle to the "off" position and keeps his hand on the handle, thereby preventing the interruption of current and the automatic application of the brakes. The main handle of the master controller has four positions : The first position, usually

Electrical Engineering

FIG. 3.—CURRENT-COLLECTING SHOE.

called the "switching" position, gives series connections to the motors with all resistance in circuit; the second position brings the automatic relay into operation and the resistances are cut out of circuit step by step until full series is obtained; the third position connects the motors in parallel; the fourth position brings the automatic relay into operation again, cutting out the resistance step by step until full parallel is obtained. It is unnecessary to pause on each notch of the controller until the corresponding motor connections are completed, but the handle may be moved directly to either the series or parallel positions, when the control apparatus automatically notches up step by step until the position is reached corresponding to the particular notch on which the handle is placed. The starting current, and therefore the rate of acceleration, may be adjusted by means of the setting of the automatic relay; this relay consists of three coils, two of which have movable plungers fitted with copper discs for bridging contacts in the control circuit, the three coils having a common magnetic circuit. The two coils which have movable plungers are connected in the control circuit and the third coil is a heavy current coil connected in the motor circuit. The function of the two coils in the control circuit is to lift the short-circuiting copper discs and thereby open one of the control circuits, the discs being held up until the motor current in the series coil has fallen to the pre-determined value for which the relay is adjusted. The contacts in the relay are never used for breaking circuit, and are, therefore, not liable to cause trouble by burning. The construction of the control apparatus throughout is of non-inflammable material, and the whole of the insulation is of mica. The whole of the cable for the control, lighting, and heating circuits, etc., was supplied by Chas. Mackintosh & Co. Practically all the wiring is in the driver's cab, and the connecting train wires and through shoe cable are fixed on the

roof of the coach so as to be out of reach of unauthorised persons. The coaches are heated by electric radiators suitably grouped in the various compartments.

From the last paragraph of our article of last week describing the track equipment it might be inferred that Messrs. Siemens Brothers' cable contract included the low-tension cables in connection with the track. This, however, is not so, for the whole of the low-tension feeder cables between the sub-stations and the track, as well as the cross-bonds, jumper cables, &c., were supplied by Chas. Mackintosh & Co. (22 Jewin Street, E.C.). This was a very large contract, including many miles of rubber, bitumen, and paper-insulated cables. We much regret that through a misunderstanding Messrs. Mackintosh's name was not mentioned. It has also been noted above that a large quantity of cable for the wiring of the rolling stock was supplied by the same firm.

REVIEWS OF BOOKS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

Specification and Design of Dynamo-Electric Machinery. By Miles Walker. 648 pp. 10 in. by 6½ in. 538 figures. (London : Longmans, Green & Co.) 32s. net; abroad, 38s. 4d.

There are few authors better qualified to deal with dynamo design than Prof. Miles Walker, who is not only personally responsible for much progress in the subject, but is a clear writer and an original thinker. This originality is shown in the planning of the book, which does not profess to be a complete treatise on the design of every kind of dynamo-electric machinery, but handles the subject in a way that we do not remember having seen attempted before. Addressing himself as much to the consulting engineer as to the designer, he makes the main feature of his work the second part, in which, after a few words as to the drawing up of specifications in general, he gives a series of some eighteen model specifications for A.C. and D.C. plant, including generators (both engine and turbine driven), motors, rotary converters, boosters, phase advancers, &c., all worth detailed study by those responsible for central station design and extension. Each one of these specifications is followed by a complete working out of the data of a machine to comply with the specification following exactly the methods that might be adopted in an actual designing office, and based, we believe, upon the system of design sheets used by the Westinghouse Company. It is in this dual arrangement that the value of the book lies, not, be it understood, simply in providing the engineer with a ready-made specification to copy or alter to suit his particular case, or the designer with a short cut to arrive at a machine to put forward, but in enabling the engineer by reading the design section to see why it is advisable to raise certain points and observe certain limitations in his specification; while the designer by familiarising himself with the specification section can see into what channels his designs must be directed to meet the requirements likely to be laid down. Excellent as the method of design put forward, we do not think Prof. Walker ever intended it to be followed slavishly by every reader of the book, and, indeed, there are no two designing offices where exactly the same procedure is adopted. He has given us, however, examples of the very best modern practice, and discussed them in a way that should stimulate further advance rather than lead to stagnant standardisation.

The first part of the book, although we have chosen to refer to it second, is on an equally high level, and, treating the subject in a more general way, lays down main principles, and deals successively with the magnetic circuit, the electric circuit, the manufacture and design of armature coils, insulation, ventilation, and the predetermined of temperature rise. The results of much recent research are included, and the practical points of construction which differentiate between the work of an "electrician" and that of a true "electrical engineer" are most admirably brought out. The industry and the profession of electrical engineering are distinctly the richer by the possession of such a book.

Continuous-current Electrical Engineering. By W. T. MacCall. 466 pp. 8½ in. by 5½ in. 385 figures. (London : W. B. Clive.) 10s. 6d.; abroad, 11s.

It has been the author's aim to provide in this work a manual for students in technical schools and colleges, especially those preparing for certain examinations, but the book should not be without its utility to others seeking to improve their general knowledge of electrical engineering

matters. The range covered includes continuous-current working only, and extends pretty widely into the fields connected with general principles, electrical measurement, dynamos, batteries, lighting, distribution, and traction. Mathematical theory is not deeply gone into, and real modern engineering practice is the basis upon which the treatment is founded throughout. This practical nature of the work is evidenced by the fact that the introduction deals first with the general functions of a generating station even before such matters as units of measurement are discussed. The illustrations are good and numerous, and also serve to explain the application of the principles taught to practical use. The treatment is necessarily somewhat superficial in places, but this is due more to the class of book which the author has undertaken to write rather than to the way he has written it. A large selection of examples to be worked by the student are given, and the general style of the work is of good quality.

Advanced Theory of Electricity and Magnetism. By W. S. Franklin and B. MacNutt. 300 pp. 8*½* in. by 5*½* in. About 260 figures. (New York: Macmillan Co.; London: Macmillan & Co., Ltd.) 8s. 6d. net; abroad, 9s.

Although dealing with theory, it has been the authors' endeavour, as they forcibly express it, to "keep the student's mind jammed up right against physical things," and to lift the treatment above a purely formal mathematical exercise. Starting theoretical considerations on magnetism, electromagnetism, &c., the first part concludes with a special chapter on the mariner's compass and the means by which its errors are compensated. The second part deals with electric charge, field, and potential, and culminates with an interesting treatment of electric oscillations and waves, which forms a considerable part of the book. Finally the electron theory (accidentally referred to in the contents as the *electron theory*) is briefly spoken of in Part III., which also skims over some other matters. We do not remember having seen a work taking up quite this interminate attitude between theory and practice before, and to a certain class of student a work of this nature should not be without utility.

Constant-voltage Transmission. By H. B. Dwight. 115 pp. 7*½* in. by 5 in. 14 figures. (New York: John Wiley & Sons; London: Chapman & Hall, Ltd.) 5s. 6d. net; abroad, 5s. 9d.

The main title of this book does not sufficiently explain its contents without the sub-title, which is: "A discussion of the use of synchronous motors for eliminating variation in voltage in electric power systems." The influence of the power factor on the drop in long transmission lines is, of course, tremendous, and the author's case is that not only is it of advantage economically to instal power-factor raising plant, but that dependence can be placed on such apparatus from a technical point of view for controlling the voltage of lines at the opposite end to that of usual practice. In many cases, he says, the load capacity of a line can be approximately doubled in this way, and the installation of comparatively inexpensive machines can sometimes take the place of building entire duplicate transmission lines. The matter is discussed from a thoroughly practical point of view, and methods of calculation applicable to the design of such systems are given.

Electric Railway Handbook. By A. S. Richez, assisted by W. C. Greenough. 882 pp. 6*½* in. by 4*½* in. 654 figures. (New York: McGraw-Hill Book Co.; London: Hill Publishing Co., Ltd.) 17s. net.

A wide range of matters connected with electric railway and tramway work is dealt with in conveniently concise form in this handbook. The information relates almost entirely to American practice, but in traction, more than some other branches of electrical engineering, much of the earlier work over here was founded on Transatlantic precedent, and parallel development has taken place, so that this fact is not the same bar to the utility of the volume to British engineers as it might be if other branches of electrical engineering were dealt with. Some of the tables may be found a little inconvenient on account of the use of a different wire gauge; but as a work of reference of modern practice, with none of the obsolete and redundant matter which disfigures so many handbooks, the work should prove of value.

Alternating-current Work. By W. P. Maycock. 415 pp. 7*½* in. by 5 in. 258 figures. (London: Whittaker & Co.) 6s. net; abroad, 6s. 6d.

In this work we have nominally a revised edition of the author's earlier book on "The Alternating-current Circuit and

Motor," prepared with the assistance of Mr. E. Hughes, but to a large extent we have a practically new book. It is intended for the student of limited mathematical attainments already familiar with continuous-current working, and explains the elementary theory of alternating currents partly by the aid of mechanical analogy in simple language. Power measurement is dealt with at some length, and succeeding chapters treat from a practical point of view of alternators, transformers, motors, &c., and their applications. The sets of questions at the end of each chapter will be helpful to students in mastering the contents of the book.

Single-phase Electric Railways. By E. Austin. 803 pp. 11*½* in. by 7*½* in. 346 figures. (London: Constable & Co., Ltd.) 21s. net; British Colonies, 22s. 4d.; other countries, 21s. carriage forward.

This volume contains a collection of excellently illustrated descriptions of the equipment of all the most important single-phase railways in England, the Continent, and America, going into considerable detail as regard both rolling stock and overhead construction. Most of these descriptions, which deal in all with twenty-three different railways, are reprinted from our contemporary, the *Engineer*. The object is to record work actually done rather than to enter into the controversy between the systems or to discuss the trend of future development, although in his introduction the author shows himself a believer in the single-phase system wherever there is a possibility of running heavy trains long distances.

Dielectric Phenomena of High-voltage Engineering. By F. W. Peck. 265 pp. 9*½* in. by 6*½* in. 190 figures. (New York: McGraw-Hill Book Co.; London: Hill Publishing Co., Ltd.) 12s. 6d. net.

With the greatly increased voltages now used on transmission lines in America and elsewhere, the study of the action of high-pressure on the dielectric has become of considerable practical importance. The author treats the whole question in a comprehensive way, investigates more especially the conditions for and nature of corona losses and the losses caused thereby, the conditions for sparking over, and the properties of different insulation materials. The final chapters deal with the practical design of transmission lines from these points of view, and a brief review of the electron theory is also included.

Arithmetic of Alternating Currents. By E. H. Crapper. 208 pp. 7*½* in. by 5 in. 45 figures. (London: Whittaker & Co.) 2s. 6d. net; by post, 2s. 8d.

This is intended to be used as a companion to the larger text-books on alternating-current working, and recapitulates the most generally required methods of alternating-current calculation, providing a series of graduated exercises such as should be of great assistance to the student in obtaining the practice and familiarity with the subject which is essential to a thorough insight into the principles. The whole is well arranged, the methods are explained clearly, and the diagrams throughout are admirable.

The Rare Earth Industry, including the manufacture of incandescent mantles, pyrophoric alloys, and electrical glow lamps, by S. J. Johnstone. Together with a chapter on the industry of radioactive substances, by A. S. Russell. 136 pp. 10 in. by 6*½* in. 42 figures. (London: Crosby, Lockwood & Son.) 7s. 6d. net; abroad, 8s. 1d.

The author has collected together a great deal of information as to the occurrence, preparation, and industrial uses of the metals, and their compounds, obtained from the group of minerals known as the rare earths, and other elements of more or less limited occurrence. It is a book of reference for industrial chemists, lamp manufacturers, experts, patent lawyers, &c., and covers a considerable amount of ground. The subject divides itself into the following main headings:—The Thorium and Cerium industry, including gas-mantle manufacture and pyrophoric alloys, Titanium, Zirconium, Tantalum, Niobium, and Tungsten. The last leads us to a chapter on the incandescent electric lamp manufacture, which is necessarily somewhat brief, but is up to date. Chapters follow on uranium and vanadium, and the final section of the book, from the pen of Dr. Alexander Russell, deals with the industry of the radioactive substances. The utility of the volume is much enhanced by the bibliography and references which head each chapter, and throughout the text there are numerous references to the multitude of patent specifications which are of such advantage to some connected with these industries, and such an obstacle to others.

Electricity for the Farm.—By F. J. Anderson. 265 pp., 7*½* in. by 5*½* in., 49 figures. (New York: The Macmillan Co.; London: Macmillan & Co., Ltd.) 5s. 6d. net; abroad, 6s. THE title of this book might lead the English reader, at any

rate, to expect the work to be a treatise on the special applications of electricity to farming operations, and if so he will be disappointed. The book is an incitement to the American farmer to utilise any water power he may have on his estate to work an electric lighting plant, and it gives him simple and elementary instructions how to fit up such a plant and how to wire his farmhouse. In addition there is a short chapter on "gasoline" engine plants. As in this country the distances of farms from the nearest towns are not great, the farmer here will be better advised to employ an electrical contractor to wire his house and erect his plant, and should not undertake the job with his own hands.

A B C of Electricity. By W. H. Meadowcroft. 127 pp. 6*1*/₂ in. by 4*1*/₂ in. 38 figures. (London : Harper & Bros.) New edition. 2s. net; by post, 2s. 3d.

This is a little elementary work, the object of which is to explain to young people some of the main facts about electricity and magnetism, and the way in which they are applied in telegraphy, wireless telegraphy, telephony, electric light and power, and the action of primary and secondary batteries. Although the text has been partly re-written since an earlier edition, some illustrations have been retained which, although of historic value, have no utility as examples to help in the understanding of present-day apparatus. For example, an Edison "Jumbo" machine of 1881 forms the frontispiece.

Modern Boiler Room Practice and Smoke Abatement. By J. T. Hodgson. 321 pp., 8*1*/₂ in. by 5*1*/₂ in. 209 figures. (London : "The Railway Engineer.") 3s. 6d. net; abroad, 4s.

This is a thoroughly practical manual of modern boiler-house practice dealing with the various factors which influence efficiency in working, and giving particular attention to the causes which lead to emission of smoke and the cure of this disease, a matter intimately linked up with the economical production of steam. The whole subject is one that has made great advances of late years, and it is largely due to systematised study, such as is dealt with in this book, having taken the place of the old rule of thumb methods that economies are attainable to-day that would have been impossible a few years ago.

Alignment Charts: Their Principle and Application to Engineering Formulae. By E. S. Andrews. 32 pp. 7*1*/₂ in. by 4*1*/₂ in. 11 figures. (London : Chapman & Hall, Ltd.) 1s. 3d. net; by post, 1s. 4d.

The alignment chart in its simplest form is a graphical method of obtaining results according to simple formulæ, depending on the use of suitable three-graduated vertical scales representing the variables intersected by straight lines drawn through values of two known variables in any particular case, and indicating the value of the unknown variable at its point of intersection with the third scale. There are many engineering calculations that can be made by the method, which is fully explained in this little handbook.

A Treatise on Hand Lettering for Engineers, Architects, Surveyors, and Students of Mechanical Drawing. By W. J. Lineham. 282 pp. 12*1*/₂ in. by 8*1*/₂ in. 117 plates. (London : Chapman & Hall, Ltd.) 7s. 6d. net; abroad, 8s. 8d.

The art of hand lettering on drawings is one requiring far more care and study than is usually appreciated if first-class results are to be obtained, and this is, so far as we know, the most complete treatise that has been published on the subject. Addressed principally to engineering and architectural draughtsmen, the work contains useful hints and instructions, and a comprehensive series of large plates presenting examples of different classes of lettering. An outline is given of the usual process of zinc block making, accompanied by a few remarks relating to drawing for reproduction.

Handbook of Patent Law of all Countries. By W. P. Thompson. 242 pp. 6*1*/₂ in. by 4*1*/₂ in. (London : Stevens & Sons, Ltd.) 16th edition. 2s. 6d. net; by post, 2s. 9d.

The very convenient little handbook of patent law and practice has been thoroughly brought up to date and contains summarised information as to the conditions under which patents are granted according to the laws in force in all parts of the world. It has not been thought necessary to give at any length the temporary arrangements in force regarding the belligerent countries, as these are continually being altered, and nearly all the Governments concerned have made provision for patents lost through the exigencies of hostilities being made good after the war. A special feature of the work is the completeness of the foreign sections.

The Slide Rule. By C. N. Pickworth. 122 pp. 7*1*/₂ in. by 5 in. 37 figures. (Manchester : Emmott & Co., Ltd.) Thirteenth edition. 2s. net; by post, 2s. 3d.

Mr. Pickworth's excellent little manual on the slide rule is

too well known to need any introduction to our readers. The thirteenth edition now before us has been carefully revised, and a method of obtaining fifth roots, &c., has been added, together with descriptions of new forms of slide rules and calculators, making the work even more complete than it was before.

Russian Self-taught with Phonetic Pronunciation. By Capt. C. A. Thimm and J. Marshall. 134 pp. 7*1*/₂ in. by 4*1*/₂ in. (London : E. Marlborough and Co.) Fifth edition. Paper covers, 2s.; by post, 2s. 2d. Cloth, 2s. 6d.; by post, 2s. 8d.

In these days many persons in all professions are finding the need for a certain amount of knowledge of Russian, and will receive with interest an introduction to the language such as this, which, if it does not go very far towards a real knowledge of its manifold intricacies, will at any rate enable the student who masters it to become familiar with the alphabet and acquire some useful travelling phrases and vocabulary with some degree of approximation to their true pronunciation.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Wireless Telegraphy with Moving Trains

Experiments with wireless telephone communication with moving trains on the Delaware, Lackawanna, and Western Railway in America are leading to very promising results. A special fixed station has been established at Binghamton for both transmission and reception, and, according to the *Electrical World*, an equipment is provided on board the train comprising a complete transmitter, receiver and amplifier. Steam at from 80 lb. to 120 lb. per square inch is led to the baggage car directly behind the locomotive, and fed to a Terry 5-h.p., 2,500-r.p.m. turbine directly connected to a seventy-two-pole 3,000-cycle-per-second inductor alternator. Field and armature circuits of the 3,000-cycle alternator are carried to the next car in the rear, where the radio apparatus is installed. From these instruments wires run to ground, via the car wheels, and to an antenna consisting of three parallel wires run along the roofs of four adjacent cars and flexibly connected. The apparatus is on the De Forest system. For transmission, the 3,000-cycle current is led serially through a line condenser and the primary of power transformer, the secondary of which is connected directly across three very short tungsten electrode spark-gaps in series. Across the spark-gaps are connected an air condenser and a variable spiral inductance, which determine the wave-length of transmission. Inductively coupled to the spiral inductance is the secondary spiral, also variable, which has one terminal connected to the antenna and the other to earth through two Berliner microphones in series. The receiving apparatus includes a two-circuit tuner and an audion detector in conjunction with a three-step audion amplifier.

The fixed station contains similar apparatus with a motor-driven alternator, but the amplifier is not found necessary. Telephonic communication has been carried on at fifty miles' distance, although there is some degree of irregularity in the working at present, which it is hoped that further experiments will remove. There is no difficulty, however, in maintaining communication by Morse signalling. The Company also use wireless telegraphy to a considerable extent to supplement line communication and to take its place in emergency.

ELECTRIC TRACTION NOTES

The Annual Conference of the Municipal Tramways Association was held in London on Thursday and Friday last week. Alderman H. Linsley, Chairman of the Salford Corporation Tramways Committee, in his Presidential Address, gave a general review of the work carried out by the Council during the year, and mentioned, among other things, that close consideration is still being given to the vexed question of the allocation of the burden of road main-

tenance as between the various classes of road users, and that in many matters of importance, conferences have been held between the representatives of other associations whose interests are allied to this Tramways Association. Matters so dealt with include defects in tramcar controllers, electric vehicles, and interest on tramway funds. After pointing out that 16,000 tramway employees, or 30 per cent. of the Municipal Tramway employees in the country have joined the colours, reference was made to the reductions of income which many tramway undertakings have had to sustain, and the aggregate figure to-day was put at £380,000 in municipal undertakings alone.

Among the papers read at the meeting was one by Mr. Alfred Baker, General Manager of the Birmingham Corporation Tramways, upon "Financial Problems as Affecting Tramway Undertakings during the War." The Birmingham Corporation, unlike the majority of other tramway undertakings, has taken the step of increasing its fares in order to meet the peculiar position created by the war. It is admitted that the revenue of the Birmingham tramways remained more or less steady, notwithstanding the war, but the various increases in cost of working, such as allowances to employees who have joined the Forces, and the increased price of materials, is held as a justification for higher fares which have brought in additional revenue to the extent of £70,000 or £80,000. The following figures of increases in cost of tramway material are interesting:—Iron and steel bars, 60 per cent.; trolley wire, 30 per cent.; steel tyres, 80 per cent.; and trolley wheels, 10 per cent. In the course of the discussion which followed, there was some difference of opinion as to the advisability of increasing fares, and the

opinions of many managers of the larger undertakings where revenue has remained constant or, probably, has increased during the war, were against this action.

Mr. Peter Fisher, General Manager of the Dundee Corporation Tramways, has been elected President of the Municipal Tramways Association for the coming year.

The Bristol Corporation is still negotiating with the Bristol Tramways & Carriage Co. as to the taking over of the Company's undertaking in accordance with the Act of last year. The Corporation has an option which expires on October 31st this year, and the negotiations at present are on the basis of the concessions which the Company will make to the Corporation in the event of the latter refraining from exercising its option of purchase for a period of 7, 14, or 21 years. In the meantime the Treasury has been approached with a view to ascertaining whether consent would be given to the raising of the necessary capital in the event of the immediate purchase of the Company's undertaking being decided upon. The Treasury, however, has replied that it was not considered to be in the public interest to do this at the moment. Having regard to this fact, it is proposed to apply to the Board of Trade for permission to extend for another twelve months the period within which the Corporation may exercise its option to purchase.

The "Cedes" Electric Traction, Ltd., has received instructions from the Hove Corporation to remove the overhead trolley omnibus equipment which was erected for experimental purposes. As we have already indicated, the Brighton and Hove Corporations have agreed to postpone any further action in this matter until after the war. The Company is to be paid £600 as agreed as out-of-pocket expenses.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 23rd, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

19,191/14. **Lampholders.** ST. HELEN'S CABLE & RUBBER CO. and J. C. WHITE. Corrosion-proof lampholders not requiring well glasses, in which the conductors pass through a sealing compound within the holder and the metal cap of the lamp is covered in. (Three figures.)

19,322/14. **Electric Reciprocating Tools.** J. W. MACKENZIE (International Electric Tool Co., U.S.A.). Electric hammers, &c., in which the reciprocating plunger is actuated by two solenoids. Both solenoids are supplied with a permanent continuous current, and also by means of separate terminals with an alternating current, which reinforces the field of one and neutralises the field of the other, so that the solenoids at each end are energised alternately. The continuous and alternating currents are obtained from a special generator provided with both commutator and slip-rings. (Five figures.)

2,490/15. **Motor-starters.** W. J. SHEPPARD and A. YARWOOD. Contactors for the control of resistances in automatic starters actuated by the rise of the back E.M.F. arranged to keep the control-circuit of the main contractor open at all times, except when the whole of the resistance is in circuit. (Five figures.)

8,189/15. **Accumulator-cases for Motor Vehicles.** P. A. H. MOSSAY. The cases are in the form of drawers on each side of the chassis, which can be let down on to rollers and slid out sideways. (Four figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Electrometallurgy and Electrochemistry: BRÜSTLEIN [Lining of electric furnaces] 19,809/14; MEIGS [Electrical apparatus for effecting the combination of gases] 982/14.

Switchgear, Fuses, and Fittings: HOPE [Fuses] 24,368/14; W. & T. AVERY, LTD., and GIBBS [Switch for use with weighing scales] 1,113/15; R. BOSCH [Pedal switch] 2,236/15; IGRANIC ELECTRIC CO. (Cutler-Hammer Manufacturing Co.) [Controllers] 3,283/15; SHORT [Switchfuse] 6,196/15.

Telephony and Telegraphy: HAMMOND [Wireless control] 16,328/14; THOMPSON (Soc. Anon. des Telegraphes E. Belin)

[Synchronising apparatus] 20,908/14; IMRAY (Siemens & Halske A.G.) [Selectors] 498 and 3,565/15.

Miscellaneous: WALKER [Magnetic clutches] 21,354/14; HEINSOHN [Electric welding] 2,248/14; WILKINSON [Electric drilling machines] 3,997/15; LILIENTHAL [X-rays] 4,097/14.

The following Specification is open to Inspection at the Patent Office before Acceptance, but is not yet published for sale.

Miscellaneous: F. KRUPP A.G. [Electric signalling or distant controlling plant] 12,614/15.

Opposition to Grant of Patents

Opposition has been entered to the grant of patents on the following specifications:

17,133/14. **Electrometallurgy.** T. R. HARRIS. Improvements in the electro-deposition of metal upon metal by means of high-current density, specially applicable for coating printing rollers, hydraulic rams, &c., with a revolving cathode and a sprayed electrolyte.

2,767/15. **Electrodes.** SIEMENS & HALSKE A.G. Electrodes for electrolytic purposes made from manganese peroxide.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

19,811/01. **Cable-testing.** E. A. CLAREMONT. A special design of closed tank for the testing of lead-covered cable in water under pressure.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS and TRANSFORMERS: SIEMENS BROTHERS & CO., LTD. (Siemens & Halske A.G.) [Motor control] 12,983/03; SIEMENS BROTHERS DYNAMO WORKS, LTD., and M. KLOSS [Alternator armature windings] 12,390/08; B.T.-H. (G.E. Co., U.S.A.) [Starting of A.C. motor] 13,285/06 and [Prevention of sparking in A.C. motors] 12,580/08.

Storage Batteries: H. C. HUBBELL [Battery plates] 11,862/05.

Switchgear, Fuses and Fittings: W. FAIRWEATHER (Benjamin Electric Co.) [Wireless cluster fittings] 12,998/06; B. T.-H. CO. (G.E. Co., U.S.A.) [Motor starters] 13,222/06.

Telephony and Telegraphy: W.AITKEN [Telephone indicators] 13,312/06.

Traction: B. T.-H. CO. (G.E. Co.) [Electric railway system with H.T. supply converted on the train] 13,287/06.

Miscellaneous: G. C. LARSSON [Mercury interruptor] 13,278/07; A. CLARKE [Projector lamp on Nernst principle] 13,391/09; H. J. HERBERTS [Electromagnetic advertising device] 13,740/09.

CATALOGUES, PAMPHLETS, &c., RECEIVED

ELECTRICAL PLANT AND CONTRACTING.—Dick Kerr & Co., Ltd. (Abchurch Yard, Cannon Street, E.C.) have issued a very fine illustrated book dealing in a general manner with their manufacturing plant, and giving interesting particulars of many important contracts in various branches of engineering which they have carried out. In view of the accusations of lack of enterprise sometimes made against British manufacturers it is very pleasant to see so comprehensive a record of work carried out by a purely British concern. The pages of the book, besides giving descriptions of the Preston and Kilmarnock works, illustrate many turbo-generators and other items of central station and sub-station plant, electric locomotives, motor coaches, haulage gears, &c. An extensive section deals with tramway construction, and many examples of large contracts in other branches of engineering are described and illustrated. Spanish and Portuguese editions of the work are in course of preparation.

ELECTRIC FIRES.—A very neatly produced catalogue from the Electric Supplies Co. (53 Victoria Street, S.W.), gives prices and particulars of a complete range of electric fires, most of which are fitted with "Qued" heating element already described in *ELECTRICAL ENGINEERING* (July 22nd, page 316). The designs embrace examples of both artistic merit and utilitarian economy, and the variety is such that patterns can be selected to suit all circumstances. Several patterns of the "Ensign" fire are also included, which employs a somewhat differently constructed heating element with solid fire-brick body built into a cast-iron box.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

ADJUSTABLE FITTINGS.—A card from Dugdill's Patents (Failsworth, Manchester) illustrates numerous patterns of their well-known adjustable and flexible fittings.

MOTOR-CONTROL PANELS.—A leaflet from the British Thomson-Houston Co. (Rugby), describes some new designs of motor-control panels for motors up to 7½ h.p. A sheet metal base is used on which is mounted an enclosed ironclad D.P. switch-fuse above the starting rheostat.

HOLOPHANE INDUSTRIAL GLASSWARE

THE excellent efficiency of illumination which can be obtained by the scientifically designed prismatic glassware, known by the name of Holophane, has long been recognised, and the range of reflectors made is such that one can always be selected to direct the light in the way required to give the best effect. There are, however, drawbacks to the employment of unprotected glassware for industrial purposes, such as liability to breakage, and to meet these, Holophane, Ltd. (12 Carteret Street, S.W.) have brought out a new series of industrial prismatic reflectors in which aluminium cases are spun over the outsides so as to seal up completely both ends. This metal cover rests on the apices of the prisms, and so far from interfering with the efficiency of reflection even improves it by reflecting back with its own polished surface such rays as escape reflection from the inner surface of the glass. We have thus a reflector of high efficiency which is strong, easy to clean, and not liable to tarnish. The Company has worked out accurate distribution curves for each of the many forms of reflector made and have prepared a series of useful tables by which the proper spacing of lamps of any size in any reflector can be ascertained for any desired degree of illumination.

SWITCHING COMPETITION

THE next of the series of examinations and competitions in electric light switching, conducted by A. P. Lundberg and Sons (477-489 Liverpool Road, N.) is announced for February, 1916. Full particulars and examinations will be published in the form of a pamphlet, which will be posted to all intending competitors, who are requested to send their names and addresses to the firm.

—OUR BOOK— DEPARTMENT.

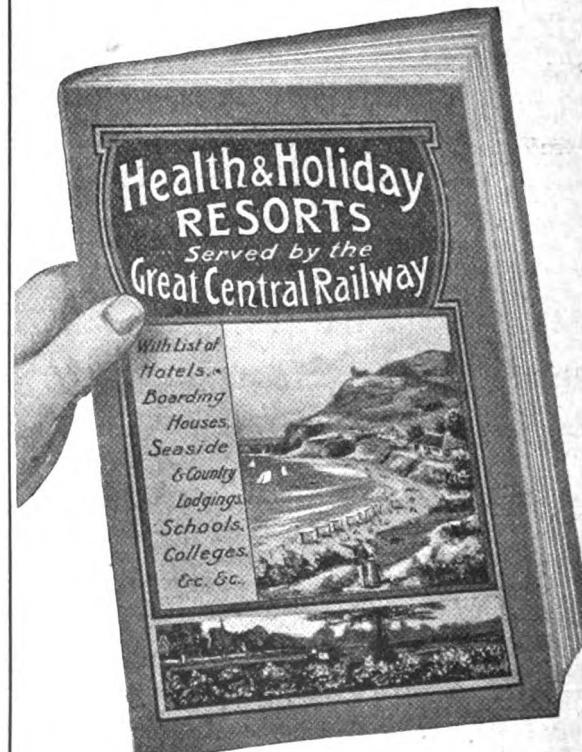

Technical Books by all Publishers sent carriage free to any address in the United Kingdom at net published prices.

Orders should be addressed to the **KILOWATT PUBLISHING CO., LTD.** (Publishers of *Electrical Engineering*), 203, Temple Chambers, London, E.C., and should be accompanied by a remittance.

List of recommended electrical books on application.

BINDING "ELECTRICAL ENGINEERING."—Vol. X. of "Electrical Engineering" (Jan.—Dec. 1914) closed with our issue of December 31st. Readers can have their volumes bound by their own bookbinder; or, they may send their numbers to THE KILOWATT PUBLISHING CO., LTD., TEMPLE CHAMBERS, LONDON, E.C., carriage paid (with the reader's name and address), and a remittance of 4s. 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad. Binding Cases (including index, but not including binding) 2s. each, or post free 2s. 4d. (Abroad 2s. 6d.) Index alone, 1d. (Post free 2d.).

For your HOLIDAYS

This Guide contains GOOD ADVICE & USEFUL INFORMATION

Sent post free on application to
G.C.R. PUBLICITY DEPT., 216, MARYLEBONE ROAD, LONDON, N.W.
SAM FAY, General Manager.

**TENDERS INVITED AND
PROSPECTIVE BUSINESS**

Generating Stations, Sub-Stations, Mains, &c.

Basingstoke.—Extensions to the mains at an estimated cost of £480 are to be carried out.

Bootle. In conjunction with the new boiler plant which is being installed by arrangement with the Ministry of Munitions, it is anticipated that a new turbine will be required shortly.

London: Hammersmith.—Seven 200-kw. transformers are required at an estimated cost of £1,050. These are necessitated by the activity of many factories engaged on war work. In order to supply Regal Films, Ltd., at Ravenscroft Park, mains extensions at an estimated cost of £160 are to be carried out.

New Zealand.—The Dunedin Council requires a 3,000 volt regulator. Further particulars at 73 Basinghall Street, E.C. Tenders by Nov. 3rd.

Pembroke (Ireland).—Tenders are invited for a cooling tower at the electricity works. Clerk, Oct. 3rd.

Plymouth.—Mains extensions are to be carried out at an estimated cost of about £200.

Salford.—The Electricity Department requires 20,000 pairs of non-metal cored flame arc lamp carbons, 15 in. by 8 mm. and 9 mm. respectively. Borough Electrical Engineer. Oct. 4th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Aberdeen.—Cinematograph theatre.

Dunfermline.—Hippodrome. H. Hare, Opera House, Dunfermline.

Falsworth.—New technical school.

London.—Cinematograph theatre, Rotherhithe. A. Bernstein, Harley Street, Bow, E.

**TENDERS RECEIVED AND ACCEPTED
AND ORDERS PLACED**

Bootle. Acting in conjunction with the Ministry of Munitions, the Electricity Committee has been successful in obtaining from Messrs. Babcock & Wilcox two boilers, which were in course of construction for another body. The contract price is £5,500.

APPOINTMENTS AND PERSONAL NOTES

The late Mr. J. C. Gill, Borough Electrical Engineer at Peterborough, left estate valued at £3,350 with net personalty of £1,895.

**MISCELLANEOUS BUSINESS NOTES AND
TRADE ANNOUNCEMENTS**

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £87 to £88 (last week £86 10s. to £87 10s.).

Change of Address.—Mr. S. G. Brown, of 4 Great Winchester Street, E.C., has removed his offices and works to Edward Road, Willesden Lane, North Acton, W.

**THE
MOST VALUABLE WORK
FOR ELECTRICIANS**

By RANKIN KENNEDY, C.E.

The coupon below entitles any reader of ELECTRICAL ENGINEERING to a complimentary copy of a booklet describing what is probably the most valuable work for electricians ever published. The necessity for electrical engineers being well acquainted with all designs for installations that have given good results will be readily acknowledged by those whom the matter concerns.

While there are numerous text-books dealing with one branch or another of electrical engineering, they are all prepared for the student, and their contents deal rather with theory than with practice.

The aim of the new Edition of "ELECTRICAL INSTALLATIONS" which has just been published is to assist the practical man who is concerned with electrical installations in any form, and this because it is recognised that there exists a very large class engaged in constructive and installation work, and a still larger class whose duty it is to take care of the machinery employed in working by electricity. Most of these men have picked up a working knowledge of their employment. What they need is to study the elements of the science of the subject. These elements are fully dealt with, and on the sound foundation thus laid, the author, who is a civil and electrical engineer by profession, and recognised as being in the front rank of electricians and engineers, proceeds to deal with every possible form of electrical installation, their principles and practical application.

ALL BRANCHES DEALT WITH.

The work includes in its comprehensive scope a review of electrical instruments, with references to indicators and recorders, and alternating wattmeters, electric pyrometers, and an electric spark recorder—all of supreme importance to electricians and electrical engineers. The heavy branch of electrical engineering, dynamos, motors, alternators, transformers, are, needless to say, given in great detail and with profuse illustrations. A section is devoted to the electric ignition and electric illumination on motor-cars. Herein will be found up-to-date information on magnetos for ignition and "constant current at variable speed," and dynamo electric generators.

Dual ignition systems are fully dealt with, so, too, are "electrical installation accessories," wiring switches, switchboards, regulators, electrical signals, telegraphs, telephones, and wireless telegraphy.

Electrical appliances in workshops, factories and steamships are now more numerous, and are daily becoming more commonly in use in every department of commercial industry; hence it is more and more necessary that mechanics, fitters, plumbers, engineers-in-charge, marine engineers and others should have an intelligent knowledge of the subjects given in this work—a knowledge which, added to his trade training, makes a man valuable far beyond the mere tradesman.

A FREE BOOKLET

To the CAXTON PUBLISHING Co., LTD.,

97, Surrey Street, London, W.C.

Please send me, free of charge, and without any obligation on my part, Illustrated Booklet on the Book of ELECTRICAL INSTALLATIONS and particulars of your plan whereby the volumes are delivered for a first payment of 1s. 6d., the balance being paid in small monthly instalments.

LOCAL NOTES

Ayr: *Electricity Profits.*—There was a net profit of £1,248 on the past year's working of the electricity undertaking compared with £1,450 in the previous twelve months. Of this sum, £1,196 is used to scrap certain out-of-date plant, and the balance is to be placed to reserve account, which now stands at £5,351. New generating plant should have been installed, but it has not yet been delivered, and is not expected now for some time owing to the war. When, however, it is installed, the higher efficiency, it is estimated, will go a long way towards counterbalancing the increase which is taking place in the price of coal and other materials.

Bootle: *Plant Extensions.*—The large demands upon the Electricity Department by firms engaged on capital contracts has had the effect of rendering it necessary to consider the installation of new machinery. A short time ago the electricity works were inspected on behalf of the Ministry of Munitions, and instructions were given that the factories were to be supplied even if it meant disconnecting the tramways and private consumers. The demands, however, have now reached such a point that it is absolutely necessary to instal new plant. For the moment the position can be met by the addition of two new boilers in the boilerhouse.

Grimsby: *Electricity Charges.*—A new scale of charges for all purposes is being introduced, which has the effect of increasing the previous charges by 6 per cent. all round. This is estimated to bring in £1,000 additional revenue, and the Committee is satisfied with this, notwithstanding suggestions that the increase should be 10 or 12½ per cent., in conformity with what is being done in many other districts.

Ipswich: *Electricity Accounts.*—The Engineer's report for the year to March 31st, 1915, shows that there has had to be a call on the reserve fund for £857. A number of special items easily explain the position. The period in question has had to bear £550 additional capital charges, all concerned with the expenditure upon the large extension scheme for supplying the eastern district without the benefit of additional revenue from that expenditure. This has been due to the difficulty of obtaining the necessary plant, and also to the fact that some of the mains which were being manufactured in France fell into the hands of the Germans at the beginning of the war. In addition, no less than £1,199 has been paid out of revenue on purely capital items, for which at present the Local Government Board will not grant loans, and a further £200 represents allowances paid to employees who have enlisted. The output for both lighting and power has been seriously affected by the war, and also by the order as to the obscuring of public lights and shop lamps.

London: *Battersea, Fulham, and Hammersmith.*—On page 325 of our issue for July 29th we mentioned that the Treasury would only consent to loans being taken up by Battersea and Fulham in connection with the proposed linking-up scheme between Battersea, Fulham, and Hammersmith. The Hammersmith Council has been in communication with the Treasury direct in order that permission may be granted to it taking part in the scheme, and it is understood that the London County Council has made arrangements for the Hammersmith application to be reconsidered at the first meeting after the recess. It is for these reasons that the Hammersmith Council has not yet sealed the agreement with the other two authorities, as recently pointed out in our columns.

Hackney: *Anticipated Deficit.*—The Electricity Committee reports that whereas at the beginning of the year a surplus of £30 was estimated upon the working of the Electricity Department for the current year, figures now placed before the Committee show that a considerable loss on the year's working will occur. After considering the best means to be adopted for meeting this deficiency, it has been decided that, having regard to the low cost of energy in the borough,

the most equitable arrangement to all classes of users will be to increase the existing scale of charges by 10 per cent. all round.

Loughborough: *Increased Charges.*—The Council has decided to increase the charges for supply by 12½ per cent., the reasons given being increases of 50 per cent. in the price of coal, and 23 per cent. in wages. There will, however, be a discount of 5 per cent. on all the accounts paid not later than the 21st day of the month following each quarter day. The increase also applies to slot meter users.

Newcastle-on-Tyne: *Reduced Prices and Apparatus on Hire.*—In contradistinction from many other electric supply authorities, the Newcastle-on-Tyne Electric Supply Co. has reduced its charges for electricity, for heating and cooking, and has also devised a scheme for hiring out apparatus upon reasonable terms. This is an attempt towards increasing the use of electricity for household uses, which might well be copied elsewhere.

Newquay: *Proposed Increase of Maximum Price.*—It has been the practice of the Board of Trade for some years to fix the maximum price in electric lighting orders at 6d. per unit instead of 8d. per unit, which was the figure originally. The Newport Electric Light & Power Co., which has a maximum of 6d. in its electric lighting provisional order, has petitioned the Board of Trade to increase it to 8d. Considerable opposition is being shown to the proposal, it being pointed out that if the Company, when it first came into the district with its scheme, had proposed that it should have a maximum price of 8d., few of the present consumers would have gone to the expense of wiring their premises for electric lighting. A petition has been sent to the Board of Trade in which it is asked that, should it be deemed advisable to grant the increase, it should be limited to the period of the war. A strong protest, however, is made against any increase.

Salford: *Satisfactory Electricity Accounts.*—For the year to March 31st, 1915, there was a net profit of £8,406, which has been transferred to depreciation and renewals account, which now stands at £21,631. The units sold for all purposes were 5 per cent. over the quantity in the previous twelve months. There was, however, a slight reduction in the case of traction, but the increase in lighting and power more than counterbalances this. The Borough Electrical Engineer's report points out that during the earlier part of the financial year a considerable amount of energy was purchased in bulk from the Lancashire Electric Power Co., but since the starting of the new turbo-generator (ELECTRICAL ENGINEERING, Vol. X., Dec. 10th, 1914, p. 629), it has been found more economical to utilise the Department's own plant to its fullest capacity. By running the new generating set continuously day and night a reduction has been effected in the fuel consumed equal to 33 per cent. per unit generated. The fuel cost is now down to 0·2d. per unit generated. Apart from the standing charge per kilowatt, the cost of purchased energy is 0·25d. per unit at the boundary substation, to which must be added transforming losses, and as the purchase of energy makes no appreciable reduction in the running costs other than fuel costs, the course pursued is undoubtedly the most economical under present conditions. The minimum standing charge of £3,000 per annum which has to be paid to the Power Company must therefore, says Mr. Robertson, be regarded meantime as a charge to furnish a standby supply equal to 1,000 kw. of plant capacity at the works.

COMPANIES' DIVIDENDS, REPORTS,
MEETINGS, &c.

County of London Electric Supply Co.—Subscriptions are being invited in connection with the Lower Thames Land Development & Power Co. Some time ago the County of London Company obtained an option of 300 acres of land at Barking for the erection of a new power station, no doubt in connection with anticipated developments in power supply for London, but will only require a certain portion for this purpose. The option on the whole area, however, is to be exercised, and subscriptions are being asked to an issue of £80,000 5½ per cent. 25-year first mortgage bearer debentures. The County of London Co. guarantees to provide a sinking fund to redeem the entire issue by October 1st, 1940.

Westinghouse Co.—A quarterly dividend of 1½ per cent. has been declared on the preferred shares, and 1½ per cent. on the common stock.

SUMMARY

WE publish an interesting communicated article on the effect of enlistment and munition working on the electricity works of a large industrial district. Our correspondent describes the way in which the various problems were solved with satisfactory results to all concerned. He also investigates what will be the best policy to pursue after the war in order that the extensions now made for temporary purposes may be put to good use (p. 404).

THE Guaranteed Wiring Scheme of the Electrical Contractors' Association has been objected to by the Board of Trade (p. 405).

WE discuss the new reduced lighting regulations which now apply to London (p. 405).

THERE were four electrical mining fatalities underground and four on the surface last year; 19 persons were injured underground, and 17 on the surface in non-fatal electrical accidents (p. 406).

PARTICULARS of the extent to which electricity is employed in mines, &c., are also contained in the reports of the divisional inspectors (p. 406).

AN official report refers to the growing use of electricity in the New South Wales mines (p. 407).

A SHORT article refers to the present position in the coal-mining industry (p. 407).

PATENT specifications on mining telephones, control of electric winding gear, lamp unlocking apparatus, and also some of electrometallurgical interest were published during the past month (p. 407).

OUR Questions & Answers page describes the design and lay-out of a telephone installation for mines (p. 408).

AMONG the specifications published by the Patent Office last Thursday were one for an improved magnetic clutch, and a new form of furnace for fixation of nitrogen depending on wipe sparks. Patents for glass-ware and alternator cooling are opposed (p. 409).

A PAPER was read before the Society of Engineers on Monday dealing with some points of contact between law and engineering (p. 409).

WIRELESS telephony over a distance of 2,000 miles has been accomplished by the U.S. Navy (p. 409).

SHORT articles describe an indirect lighting installation, a new switch, a case of lamp strength, and a Red Cross van (p. 410).

H.T. CABLES, transformers and switchgear are required at Littleborough; mains at Watford and Dublin; three-phase transformers with switchgear at Sydney (N.S.W.); mains and services at Darwen; and air-cooled static transformers at Hammersmith.—New plant will be shortly required at Aberdeen and Pretoria.—An inquiry comes from British Columbia for half-watt lamps, and the L.C.C. Asylums Committee requires a supply of electric lamps (p. 411).

THE Newcastle-on-Tyne Electric Supply Co. has devised two interesting new tariffs.—Employees of electrical firms engaged on munition work have been fined at Belfast and Dublin for absenting themselves.—The Glasgow electricity showrooms which have been fitted up by the Electricity Department, in conjunction with local wiring contractors, have been opened (p. 412).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDANT.

Drills, 6.30 to 7.30; 7.30 to 8.30.

(To-day) Thurs., Oct. 7th: Section III., technical. Section II., shooting.

Fri., Oct. 8th: Section IV., technical. Section II., squad, signalling class.

Sat., Oct. 9th: Company parade, 2.30 p.m. Route march.

Mon., Oct. 11th: Section I., technical. Section III., squad, signalling class.

Tues., Oct. 12th: Section II., technical. Section IV., shooting.

Thurs., Oct. 14th: Section III., technical. Section I., shooting.

Fri., Oct. 15th: Section IV., technical. Section II., squad, signalling class.

The Headquarters are at Marconi House, Strand, W.C. (Tel : City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

Mr. C. G. Spiers has been appointed Acting Company Sergeant-Major, vice H. N. Fullarton resigned.

In consequence of the great Recruiting March Out on Saturday, October 2nd, the Route March arranged for that day was postponed until Saturday, October 9th.

Members who have not yet been measured for their uniforms are requested to give notice to their Section Commanders when they will be able to attend for measurement, so that an appointment can be made with the tailors.

The work in connection with the new headquarters at Chester House, Eccleston Place, S.W., has been commenced, and it is proposed that drills shall start there on Oct. 18th.

THE EFFECT OF ENLISTMENT AND MUNITION WORKING ON THE ELECTRICITY WORKS OF A LARGE INDUSTRIAL DISTRICT

[BY AN ELECTRICITY WORKS ENGINEER.]

THE war has affected all large generating stations serving important industrial districts, and a brief account of the difficulties which have had to be solved by the writer may be of interest to other central station engineers. Undoubtedly the effect has been felt most seriously in connection with the staff and workmen.

At the start of the war we lost several of our best men through their being attached to various Territorial Forces; by the time we had been able to fill these vacancies the majority of the younger members of our staff had either actually enlisted or were making arrangements to do so. We then obtained the consent of the War Office to retain the services of any man we really required, and it has been fortunate that we did so; the men we have been able to obtain in order to fill the vacant posts being of a very inferior type in every respect. We have found that the interests of the station have been served most efficiently by granting to our remaining men a fair war bonus, and arranging that they shall have some amount of overtime at rather favourable rates of pay. In addition, we have again called into active work a few old men who had practically been pensioned off after having served the department for many years as drivers, firemen, or labourers.

The district being a heavy engineering centre, every workshop was soon running overtime and night shifts on munition work; the skilled tradesmen in these shops are paid at a special rate in many cases, or have special piecework rates. This fact, coupled with the considerable amount of overtime and week-end working which they are putting in, has resulted in their making about treble an ordinary week's wage. As may be imagined, it has not been without its effect on our own skilled workmen. In order to satisfy our own men we granted a fairly good war bonus, and, being below our proper complement, the men were able to put in a small amount of overtime. This arrangement gave satisfaction for some months, and then discontent and grumbling and demands for a higher rate per hour, or permission to transfer to a munition firm, became the order of the day.

In this matter the writer finds that we are not alone, several generating stations in similar circumstances having been annoyed in the same manner. We resolved, however, to take a firm stand on the matter, refused the proposed increase and also permission for the men to leave. In a few days the men fully realised their position, and also reluctantly admitted that, as several members of the official staff had had to refuse good offers of appointments elsewhere, they were merely taking their share in the common sacrifice.

When this stage was reached, we called the men together and informed them that, in order to give them a somewhat better chance of earning the enhanced wages enjoyed by the men in the ordinary workshops, we had decided to go forward with several minor jobs which had been put on one side owing to the war, and that on this account they would have opportunity for a good deal of week-end work. So far the arrangement has worked well. Had we not shown a firm attitude at first, however, there is no saying when and at what point the demands would have ended.

The chief engineer of a neighbouring electricity works solved the problem in the following rather neat fashion. He had his plant in excellent repair when the war broke out, a fair amount of stand-by plant, and another large set three-parts erected. This left his workshop rather slack; to retain his men he arranged to take in a certain amount of munition work. This has kept his repair staff together, and allowed them to earn a good wage without dragging them out of the department. The same plan has, I believe, been adopted in one or two other towns. The effect on the load has been to increase the power demand by about 28 per cent. This demand, however, has been fairly well distributed throughout the twenty-four hours, so that the only alteration in the shape of the load curve has been to fill up some of the hollows, both overnight and at the week-ends. This has brought the station load factor up from about 22 per cent. to well over 30 per cent., and the problem now is to obtain new plant in time to serve the still increasing load. Owing to the fact that much of the new load and the normal power load are of the same character, the diversity factor has not been affected to any extent.

On one point in the management of the department we are able to congratulate ourselves.

When it became evident, a year or two back, that all

future extensions would be on the three-phase system, we were at first undecided whether to take out some of our old sets to make room for the turbo-alternators or whether to extend the buildings for that purpose. The first policy would have meant that we should have had to supply the three-wire and traction loads through the three-phase plant and the rotary converters. Our D.C. sets were in good condition and really reliable plants; finally we decided that instead of spending our capital in paying off the unredeemed loans on the D.C. plant, we would keep the old sets for a time and lay out our money in buildings.

It has been most fortunate that we did so, as the turbo sets would, under the other policy, have been loaded up to the limit, and it would have been quite impossible to do what we do now, namely, give each turbo set a thorough examination from time to time, and meanwhile supply the three-phase demand through the old D.C. sets and the rotary converters, running inverted. The lighting and general domestic load has been allowed to mark time during the last twelve months; the work in making power connections absorbs the whole of the time of our available labour, and as much material as we can get delivered. In the matter of rising coal prices we are protected by our usual agreement on the matter.

In this district, as in most large industrial districts, there are many large firms who, for one reason or another, prefer to run their own private generating stations. In many of these firms, in normal times, we have only been able to get our supply in for the purpose of week-end and sectional working, and in many cases could not get in at all. To-day the cry is for connections as fast as we can make them; our outside staff and the installation contractors are working week-ends continuously in order to satisfy these demands. The managers of these works have now fully realised that motors can be manufactured and installed much quicker than new generating plant for their own stations can be arranged for; we are hoping that when peace is again restored that we shall keep much of this work solely on the grounds of convenience and handiness.

The traction load has dropped to some extent, as the full service of cars is not being run at the present time.

At the conclusion of the war the central station will probably benefit from the fact that many of the private works' generating stations will require extensive repair and renewals after the long spell of hard work through the war. Capital will not be any too plentiful for this purpose, so that it will probably suit many firms to stick to the outside supply of electricity rather than to lay out capital on their own stations.

Another aspect of the effect of the war on the generating station is given by the supply at a well-known seaside resort managed by an acquaintance of the writer. The load at this place is principally a summer load, and with the exception of a demand for various pleasure grounds on the front, is an evening lighting load. This summer the lighting on the promenade and the majority of that in the side streets has been dispensed with; there is still the load from the "Fun City," but in addition it has been possible to pick up quite a substantial lighting load by giving a supply to a neighbouring military camp. This supply will last right through the winter, and will, in fact, furnish the station with a better winter and all-the-year-round load than it has ever experienced since it started up.

In conclusion comes the consideration of the capital expended in war work extensions and the "after war" position of our own and our Allies' trade. The writer considers it necessary to take these two points together, owing to the fact that if we do not make provision now for the "after war" situation, then our Allies and ourselves will experience an exceedingly grave trade depression, which will hit the central station industry as hard as any other.

Previous to the war trade was booming, and would no doubt have remained good for many years; as an industry the central stations were sharing in the prosperity, and, had the war not happened, it is quite probable that the extensions of plant which we have now made in, say, ten months, would have had to have been made in the course of fifteen months at the outside. It is at this point, however, that the cases cease to run parallel. Personally, the plant of which the writer has charge has been increased by about 30 per cent., and further large increases are necessary, which in the matter of capital cost will be more expensive than plant installed two years ago. Had the war not occurred, the whole of the capital laid out in these extensions would have been kept working year after year on a steadily increasing load, and thus been able to earn a fair rate of interest on the outlay.

Now we are faced with the probability of this enormous addition to our capital expenditure being unable to earn its

standing charges, owing to the plant being idle through bad trade after the war. When peace is restored we shall first require to restock our arsenals with the safe minimum amount of war material. As we are increasing the factories at which such material can be made, it follows that this restocking cannot take long, and then will come a heavy slump in trade unless we act now.

When the restocking is complete there will be literally hundreds of motors and thousands of machine tools thrown on the market; at the same time North-eastern France, Belgium, Russia, and Serbia will need their homes rebuilding and their factories putting in a position to supply their needs once again. They will, however, lack the capital necessary to carry out this work.

Will it not pay us to arrange that this capital shall be found by the British Empire, and that our munition factories shall be swung over to industrial work quicker than they were swung from their previous work to that of munition-making? The use of British capital would keep British factories in full work, and along with this boom the generating stations would be kept busy and able to make a return on their recent heavy capital outlay.

The method of raising the capital should not be difficult; let us consent to be taxed on a war basis for a sufficiently long period until we find the money necessary to put our Allies on their feet again. Capital and industry soon react from country to country, and it would not be long ere our friends would be able to start finding their own capital again, thus relieving us of the burden.

The above may seem a drastic idea, but let us consider the alternative. Bad trade at home, discontent and perhaps serious rioting, and undoubtedly heavy local taxation in the matter of poor law rates. On top of this we should have the galling spectacle of trade, which we might have had, going to America.

Let us make no mistake; if we do not come forward and find the capital to rebuild the towns of our Allies, then America will do so, and will not only capture the immediate trade by doing so, but, by the very act of thus helping those countries, will have them in financial bondage to her for many years. The trade would thus go past us to them, and we should be quite powerless to prevent it doing so. So serious does the position appear to the writer that he would advocate the thorough discussion of some scheme to prevent the indicated trade disaster, which our usual methods will drop us into at the finish of the struggle. Public opinion and public men should be influenced on the matter; above all, the time to start is now.

THE E.C.A. GUARANTEED WIRING SCHEME

Board of Trade Objection

AFTER working for so long on its guaranteed wiring scheme, and at a time when there seemed every possibility of the scheme being put into operation, the Electrical Contractors' Association has received a somewhat unexpected set-back at the hands of the Board of Trade. The facts are set out in the October issue of *The Electrical Contractor*, the official journal of the Association, and from these we gather that the Board of Trade comes into the question through the necessity for amending the Articles of Association to deal with the wiring scheme. These amendments had been duly approved by the Association and had been sent up to the Board of Trade for sanction. It appears, however, that the Board of Trade opposed the new clauses in the Articles of Association on the ground that the guarantee scheme sought to confer a benefit on a section of the installation trade, i.e., upon the members of the Electrical Contractors' Association, and was not intended to confer a benefit on the installation trade as a whole, which, it was contended by the Board of Trade, is the *raison d'être* of the Association. Something of a climax has been brought about by the Board of Trade threatening to revoke the Charter of the Association if the amendments to the Articles of Association are persisted in. In the words of our contemporary, "this leaves the guarantee scheme, at least for the moment, high, dry, and inactive."

The position, of course, is open to a good deal of controversy, inasmuch as it is evident that the Association has, in the past, carried on a good deal of work which was clearly wholly for the benefit of its members, and to which the Board of Trade had not taken exception. We are inclined to agree with the view of the Association that the guaranteed wiring scheme is much more calculated to benefit the installation trade as a whole than many other spheres of action of the Association in the past, if only for the "tone" which the existence of such a scheme as that in contemplation must

introduce into the wiring contracting business, notwithstanding that at first glance it might appear to confer a benefit upon the members of the Association alone. The effect of any such scheme must be to raise the general level of installation work in this country, but for the moment the Association is faced with the position as it is put by the Board of Trade; and a special meeting was held in Leicester yesterday, after we had gone to press, when the whole position came up for discussion.

LONDON LIGHTING

THE new regulations with regard to lighting in London were published on Friday, and came into force immediately. They apply to the whole of the Metropolitan police area and to certain districts outside, representing in all nearly 700 sq. miles. Private houses, railway carriages, and shops are included, the first two mentioned being dealt with by specific regulations for the first time. The regulations aim at carrying out the scheme outlined by Sir John Simon in the House of Commons a fortnight ago, when he stated that the main object it was desired to secure was uniformity in lighting rather than absolute darkness. With this end in view it is provided that bright lights in premises of all descriptions must be shaded or the windows must be screened.

So far as domestic lighting is concerned, it is probable that the majority of consumers will meet the regulations by the proper use of blinds and curtains to their windows. In those cases where it is not convenient to put up blinds or to replace some of the transparent blinds with others of a darker material, a great deal can be done towards diminishing the amount of light thrown through a window by hanging lamps lower and by the use of deeper shades totally obscured on the outside, such as the deep 10" x 5" green and white opal shades. Where Holophane and similar shades are used, their utility will not be impaired by covering with cardboard cones, and these, of course, will prevent the light being transmitted outwards through the glass. We trust, however, that, on the whole, the use of blinds will be resorted to rather than a diminution of light, and that the homes of the people will be kept brightly lighted as hitherto. There has been no "frightfulness" on account of the recent Zeppelin raids, but a reversion from bright and cheerful interiors to dimness might just possibly produce in some homes a moral atmosphere of depression, which would be a slight step in the direction of the general discomfort which the Zeppelin attacks aim at producing.

In the case of shop-window lighting it will be safe to say that the same principles must be followed as those advocated ever since the first reduced lighting orders came into force. It is quite time to discard many of the temporary arrangements in the case of shop lighting, for, of course, it is to be expected that the present reduced lighting order will remain effective until the close of the war.

The enforcement of the new regulations is apparently largely in the hands of the special constables, most of whom have, needless to say, not made a study of illuminating engineering; their instructions and criticisms will therefore frequently have to be received with indulgence and patience, for it must not be forgotten that an error on the side of over-zealousness is a virtue rather than a fault.

ANSWER TO CORRESPONDENT

TRANSFORMER.—You tell us in your letter that a fault developed in a colliery so serious as to soften the insulation of and decentralise a cable capable of taking more than twice the normal load, but that the effect on the cable was not serious enough to break down the insulation resistance, but you do not tell us what you want to know. What is the problem that puzzles you?

A Mazda Lamp Phenomenon.—We are informed by the British Thomson-Houston Co., Ltd., that they received the following letter two or three days after the London Zeppelin raid:—"I learnt a rather interesting fact yesterday which I thought you might like to know, as you might possibly be able to turn it to account. In one of the buildings in — where the Zepp. bombs dropped, everything around was shattered except one Mazda lamp, which remained in solitary glory. I have not been to the building myself to see this great sight, but my informant was one of the directors of Messrs. —, and he was quite sure about it."

Killed in Action.—In the recent lists of casualties we regret to notice the name of Lieut. C. H. Scholey, of the Rifle Brigade, only son of Mr. H. Scholey, of Messrs. Scholey & Co. Lieut. Scholey was apparently killed in the great advance in France, for his death was dated Sept. 26th.

ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

ELECTRICAL ACCIDENTS IN MINES IN 1914

PART I. of the Annual Report of the Chief Inspector of Mines, for 1914, dealing with divisional statistics, is now published. It appears from the tables of accidents reported that during the year under review there were four separate fatal accidents underground due to electricity (one in Scotland, two in Yorkshire, &c., and one in South Wales), and a like number on the surface (one each in Scotland and the northern district and two in the Yorkshire district). Each of these accidents caused one death. One electrical fatality on the surface involving one death is reported in the case of metalliferous mines, but none underground. No electrical fatalities are reported from quarries. The non-fatal underground accidents in mines amounted to 18 (distributed among the following districts:—Scotland, 3; Northern, 1; York, 3; Lancashire, 3; South Wales, 6; and Midland, 2). These caused injuries to 19 persons, as in one of the South Wales cases two were injured in one accident. Seventeen non-fatal surface accidents, each involving the injury of one person are reported (Scotland, 2; Northern, 3; York, 5; South Wales, 4; Midland, 3). No persons are reported to have been injured in non-fatal accidents in metalliferous mines or in quarries.

It is mentioned in the report that Mr. Robert Nelson, H.M. Electrical Inspector of Mines, is now on active military service, and that Mr. W. E. T. Hartley (Junior Inspector of Mines) is acting as Electrical Inspector in Mr. Nelson's absence in the Scottish and Northern divisions, while Mr. W. J. Charlton (Junior Inspector) has been transferred temporarily from the Northern to the Lancashire, North Wales, and Ireland Divisions, and now acts as Electrical Inspector for the districts not covered by Mr. Hartley.

REPORTS OF THE DIVISIONAL INSPECTORS OF MINES

AGOOD many references to the use of electricity in mines are contained in the reports of the Inspectors of Mines for the different districts for 1914, all of which have now been published. The report for the Yorkshire district has already been dealt with in our columns (*ELECTRICAL ENGINEERING*, Sept. 2nd, p. 362).

Scotland.

The report of Mr. H. Walker (who acted in place of Col. C. L. Robinson, who was serving at the front, and has since been killed in action) for the Scottish district gives the total number of electric coal-cutters in the district as 747 (515 disc, 216 bar, 12 chain, 2 percussive, and 2 rotary heading machines); this is an increase of 37 since the previous year, and compares with 166 compressed air machines.

The accidents due to electrical causes were one fatal and two non-fatal on the surface, and one fatal and three non-fatal underground. The underground fatal case was to a man afterwards found to have had a weak heart, who probably received a shock of about 290 volts three-phase from a fuse-box. One of the non-fatal underground accidents is stated to have been the result of using cables of German manufacture and poor quality. One prosecution for contravention of the electrical regulations turned on the date at which a certain unarmoured cable was removed from one part of a mine to another for use on a haulage road. The cable was held not to be exempt as having been in use before June, 1911, as it was being used for a different purpose.

Three thousand three hundred and sixty-five electric safety lamps are in use in the district, against 1,160 in the previous year. The makes are as follows: Ceag, 1,411; Gray-Sussmann, 85; Oldham, 60; Wolf, 1,791; and Float, 18. The aggregate horse-power of motors used in the 340 electrically-equipped coal mines of the district is given as 106,972 underground, and 30,183 on the surface. The increase on the total over the previous year is 17,516. In the Scottish metalliferous mines motors aggregating 527 h.p. are used, and no electrical accidents are recorded.

Lancashire, North Wales, and Ireland.

The report of Mr. A. D. Nicholson for this district records a diminution in the use of electric coal-cutters from 36 to 34,

while there is a slight increase in the compressed-air machines of which over 300 are in use in the division. As regards accidents, there were none due to electrical causes in Ireland, and only three, none of which were fatal, in the remainder of the area; these only involved slight burns. Among the dangerous occurrences, however, a fire is referred to as having been due to an electric cable.

Two thousand three hundred and ninety-eight electric safety lamps are in use, made up as follows: Oldham, 915; Ceag, 716; Gray-Sussmann, 495; Wolf, 264; and Thomson-Rothwell, 8. The aggregate horse-power of the motors in the 137 electrically-equipped coal mines in the district is 13,117 on the surface, and 22,502 underground.

No electrical accidents are reported in the metalliferous mines where motors aggregating 2,316 h.p. are in use.

South Wales.

It is well known that electrical coal-cutters are still only used very little in South Wales. The figure given in Dr. W. N. Atkinson's report is 44, and of these 38 are for machines. There was one fatal accident attributed to electricity underground, and six non-fatal accidents, involving injury to seven persons. Four persons were also injured by electricity in non-fatal accidents on the surface. The fatality was to an assistant electrician who received a shock while attempting to replace the cover of a 500-volt switch-box without having previously cut off the current. The non-fatal accidents were all slight injuries, mostly caused by irregular or improper manipulation of electrical plant, and one by a faulty cable connection. There were no prosecutions for contravention of the electrical rules.

The electric safety lamps in use in the district are given as 23,066 in number, of the following makes: Bristol, 2; Ceag, 16,057; Float, 99; Gray-Sussmann, 80; Oldham, 5,753; Wolf, 1,033; and Varta, 42. The aggregate horse-power of motors in the 291 electrically-equipped coal mines in the district is 93,832 on the surface (including 16,372 for winding), and 100,443 underground. The totals for the metalliferous mines are 720 h.p. on the surface, and 135 h.p. underground.

Midland and Southern.

Mr. H. Johnstone's report for the Midland and Southern division records the use of 84 electrical coal-cutters (35 disc, 20 bar, and 29 chain), as compared with 139 compressed-air machines, although it is noticeable that the total tons of coal cut by the electrical cutters during the year is slightly in excess of the output of the compressed-air machines. No electrical fatalities are reported in collieries, but there were two non-fatal cases underground, and three on the surface. Of these three were apparently due to carelessness in replacing fuses, and one to an error made in connecting up.

One thousand eight hundred and fifty-six electric safety lamps are in use in the district, of the following makes: Bristol, 29; Ceag, 1,064; Gray-Sussmann, 93; Oldham, 362; Wolf, 306; and Float, 2. The aggregate horse-power of motors in the 131 electrically equipped mines in the division is 12,164 on the surface, and 41,105 underground.

One electrical fatality is reported in the metalliferous mines section. In this case a man was exceeding his instructions in making connections. The horse-power of the electric motors in these mines is 5,835.

Northern District.

Mr. J. R. R. Wilson records an increase from 134 to 156 in the number of electrical coal-cutters at work. They include the following patterns: Disc, 58; bar, 33; chain, 63; and percussive, 2. Compressed air are, however, more used, being 546 in number.

One electrical fatality is recorded on the surface, but none underground. One person, however, was injured in a non-fatal electrical accident underground, and four on the surface. The fatal accident was the unfortunate termination of a practical joke. The report also refers to a prosecution of officials of the Clifton Colliery, Workington, for using an earth cable of less than the size required by the rules, and using an unarmoured cable in certain circumstances. The Bench found that a technical offence had been committed, but did not inflict any further penalty than the payment of costs.

The electric safety lamps in use number 6,987, of the following makes: Bristol, 10; Ceag, 992; Float, 17; Gray-Sussmann, 4,276; Joel-Fors, 38; Oldham, 1,330; Thomson-Rothwell, 2; Wolf, 322. The aggregate horse-power of motors in the 279 electrically-equipped collieries of the district is 78,936 on the surface, and 90,875 underground. The metalliferous mines account for a further 466 on the surface, and 408 underground.

ELECTRICITY IN MINES IN NEW SOUTH WALES

THE annual report for 1914 of the Department of Mines, New South Wales, Australia, does not record in the section devoted to accidents any fatalities due to electrical causes, although two non-fatal electrical accidents are reported underground, and one on the surface, one person having been injured in each case. One was due to a damaged trailing-cable of a coal-cutter. One was a case of burns from a short-circuit caused by careless replacement of a fuse, and the other was due to signal wires being live owing to a mistake in the connections of a transformer.

There are few electric safety lamps in use. Some, however, are on order, but have not been delivered owing to the war. The following types are approved for general use: Bristol, B.A.C., Ceag, Turquand-Kingsway, Gray-Sussmann, Manley & Sandy, Joel-Fors, Oldham, Thomson-Rothwell, Varta and Wolf. Six types for officials and special use are also approved. A table gives details of the electrical equipment of 53 collieries. The installations are mostly of moderate size, only one being as large as 2,000 kw., and of the remainder only six over 500 kw. A.C. is not employed as much as D.C. Electric blasting, signalling, and telephones are in use in the majority of cases. Further references to electrical working are contained in the reports of the district inspectors.

A separate report also appears by Messrs. W. Corin and J. F. Dent, Electrical Inspectors of Mines. From these it appears that 5 out of 11 candidates were awarded certificates of competency as mine electricians, making a total of 86 now on the register, while 49 out of 75 passed the electric motor drivers' examination; at a similar examination relating to metalliferous mines, six candidates passed. Speaking of the electrical accidents already referred to, Mr. Corin remarks that "the case of shock from an electrical coal-cutter points to the advisability of the metal work of these machines being efficiently and continually earthed while they are connected to the mains." This matter, he continues, is being considered in connection with the revision of the rules. Mr. Dent reports considerable increase in electrical working in the New South Wales collieries. The general condition of the installations, he writes, is good, and several managers have provided for the earthing of coal-cutter motors, although the rules at present in force do not insist on this.

THE COAL SUPPLY OUTLOOK

SINCE we discussed in our Mining Section on August 5th (p. 328) the general coal-mining position as it was likely to affect the electrical industry, and particularly in the light of the National Conference between the coal industry and the Government, things have been comparatively quiet, to the extent that the possibility of any further open hostility between the men and the owners has for the moment been avoided. The question of increasing output, however, has been taken a step further, for as the outcome of the hints given at the National Conference that the industry generally will be willing to discuss modifications in the general working conditions, a conference between representatives of the industry and the Home Office took place early in September. This conference was convened by the Coal Organisation Committee. The proceedings at this conference were private, but a statement was issued by the Home Office indicating that considerable differences of opinion still existed between the men and the owners, particularly in regard to any interference with the Eight Hours Act. The point of view of the men would seem to be that this should only be resorted to in the last extremity, and that efforts meanwhile should be made—indeed, they are being made—to secure greater regularity in the attendance of miners at the pits and less absenteeism. The men apparently realised that in taking this attitude they might be jeopardising the nation's supply of coal, for the President of the Miners' Federation, the official notice pointed out, stated that if these efforts failed, the question of suspending the Eight Hours Act would be taken into consideration. That no further conference has been held of sufficient public interest to warrant the issue of an official *résumé* of the proceedings is, perhaps, an indication that an improvement has manifested itself in the desired direction.

Death in a Colliery Power Station.—An inquest was held recently into the death of an apprentice in the power station at Kinglassie Colliery, Fife. The deceased was found lying near some switchboard connecting cables, but the chief electrical engineer of the station failed to find any leakage which could account for a shock. The medical evidence found no other cause of death, and the jury reported that they found no evidence as to the cause of death.

Electric Safety Lamps.—It is reported in the *Standard* that in connection with the introduction of electric safety lamps in a portion of the South Wales coal field that coal-cutters who use them are offered 1d. per ton extra.

ELECTRICAL MINING AND METALLURGICAL PATENTS OF SEPTEMBER

Mining.

A SELF-CONTAINED portable telephone specially intended for use in mines is described in Specification No. 4,526 of 1914 by A. Dootson.

In Specification No. 17,548 of 1914, the German Siemens-Schuckert Co. describe a controlling arrangement for electric winding and haulage gears, having means for preventing the control lever at any point from being moved at a rate exceeding a predetermined maximum, and positive mechanical means in gear with the motor for automatically returning the lever to the "off" position at the end of the travel.

Improvements in mechanical details of an apparatus for magnetically unlocking miners' lamps form the subject of a specification by O. Oldham, numbered 18,442 of 1914.

A system of combined audible and visual signalling for mines has been patented by H. Green and W. de M. Landon, and is described in Specification No. 18,780 of 1914. Two pairs of relays are employed, whereby the audible and confirmatory visual signals may be given by the on-setter to the engine-man, and the signals are automatically reset by the movement of the engine or by a succeeding signal, while allowing of a fresh signal being given during the wind without such signal being annulled until the engine starts.

Electro-metallurgical.

In Specification No. 19,818/14, B. Schwerin describes a process of magnetic separation of ores from slimes in which there is added to the slimes before separation an electrolyte which loosens the close adhesion of the particles of the substance, so that one component tends to separate out by settlement.

G. Brustlein (Norway), in Specification No. 19,809 of 1914, describes a method of constructing the lining of electric furnaces, consisting of stamping the lining material around the rings of cast steel or other material which are to be used subsequently for heating the furnace, instead of stamping it round a special template.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

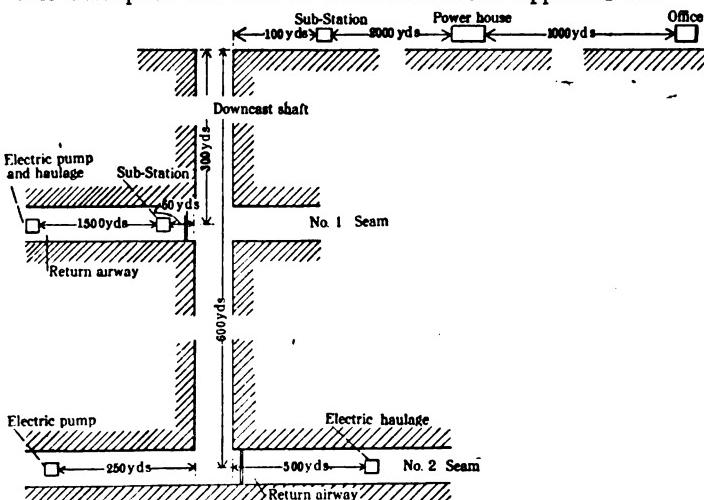

QUESTION No. 1,463.

How are the values of resistances for a controller for a 585 h.p., 485 r.p.m., 2,200-volt, 25-cycle, three-phase slipping induction motor obtained? Rotor star connected, 700 volts, standing 360 amperes full load. The controller to have 12 stops. Is it standard practice to cut resistance first out of B , then R , then Y phase, and repeat until finally short-circuited, or to cut resistance out of all three phases together? If the former method is used, would it have an unbalancing effect on the rotor on any step, and tend to make it hunt, as one phase would be loaded more than the others? How would the resistance be calculated to give any particular speed on any particular step?—RESLETT.

(Replies must be received not later than first post, Thursday, Oct. 14th.)

ANSWERS TO No. 1,461.

In fitting up a new mine with telephone instruments between underground sub-stations and power stations and other surface buildings, what are the factors entering into the problem which require special attention? What would be the most suitable description and sizes of cable and class of apparatus and

general arrangement of circuits to meet the conditions shown on the sketch? The system is to be arranged so that a person could speak to the station or surface office from any other point, or could speak between any two points underground, and must be arranged so that other points about mine can be added later.—"WORKER."

The first award is given to "J. A. M." who writes as follows:—

A central battery system would be most suitable with battery and switchboard at the power station. At sub-stations, office, &c., magneto mining pattern telephones should be installed, these instruments being enclosed in gas and watertight iron cases. Suitable standard instruments can be obtained from any makers of telephones. At each instrument should be fitted a standard instrument protector, consisting of a pair of fuses, heat coils, and carbon block arresters.

Between power-house and office or sub-station on the surface the wires could be 1/18 S.W.G. bare open wires carried overhead on insulators attached to oak cross arms on creosoted wood poles.

Poles on surface: P.O. medium or light size, as given below, planted 5 ft. deep; oak cross arms, $4' \times 2\frac{1}{2}' \times 2\frac{1}{2}'$, each

long enough to carry two pairs of wires with standard P.O. cordeaux insulators on $\frac{1}{2}$ " pins.

From surface sub-stations down shaft and into workings, use 3/22 S.W.G. dry solid paper-insulated and lead-covered cable jute served over lead, then armoured with a layer of galvanised steel wires and jute served and compounded overall. In shaft the cable could be supported by 2-ft. long elm or pitch pine cleats fixed to the buntons, and in the seams it could be carried by canvas or leather suspenders fixed, say, 3 ft. apart hung at the sides of the roads.

Shaft cleats spaced 100 yards apart, the first cleat being placed at the top of the shaft.

A plan giving the following particulars accompanies "J. A. M.'s" reply, and allows for future instruments by including spare pairs in the underground cables. Future wires on the surface where the run is overhead can easily be added at any time as required:—

From office to power-house.—One pair of open wires on 28 ft. P.O. light poles 270 ft. apart.

From power-house to sub-station.—Five pairs of open wires on 28 ft. P.O. medium poles 135 ft. apart.

From sub-station to No. 1 seam.—300 yards 9-pair cable (five spares).

To sub-station, No. 1 seam.—50 yards 4-pair cable.

From No. 1 seam sub-station to pump and haulage.—1,500 yards 2-pair cable (one spare).

From No. 1 to No. 2 seam.—300 yards 4-pair cable (two spares).

To pump in No. 2 seam.—250 yards 2-pair cable (one pair spare).

To haulage in No. 2 seam.—500 yards 2-pair cable (one pair spare).

The second award (5s.) is made to "OAKDENE," who has sent the reply below:—

The first considerations in regard to mining telephones are reliability, strength, and simplicity. First cost, although an important factor, should not be allowed to weigh unduly, because a breakdown in communications in a mine means loss of output, which easily resolves itself into £ s. d.

The simplest method of connecting a system of mine telephones is to arrange them all in parallel, so that there are no switching arrangements, and a call from any one point rings all the bells on the line. If it be thought a nuisance to have bells ringing in the office just because two men want to speak together below ground, then the system can be split up into two parts, and the office section joined up when required by means of a switch, which might with advantage be placed in the power-house. There is a corresponding advantage, however, in having all the 'phones on one line, because when the men below-ground know their conversation can be heard in the office, they are not likely to waste so much time over it.

Agreed that the parallel system is best, what instruments should be used? The parallel system makes too great a demand on the batteries to enable the battery-ringing system to be of use, and, in addition, there is a big expense attached to the maintenance of a large number of cells spread over large areas.

The magneto system is good, but where a large number of telephones are coupled in parallel the generators must be very powerful, and any weakening soon shows up in feeble and intermittent rings. Again, code ringing is practically a necessity when there are a large number of instruments, and code ringing by magneto is not very convenient. Moreover, the magneto handle forms a very convenient coat-hook, which often means the circuit is opened at the generator springs by the strain put on the handle.

The best system is that which employs a main battery of about 24 volts (accumulators are best) above ground, and no batteries at all below. The instruments can be in iron or wood, according to whether they are fixed in dry or wet places. Any number up to forty can be connected in parallel on one line, which consists of a metallic pair and an earth return. The calling is by code, and is done by depressing a push-button at the calling instrument the requisite number of times. This push closes the circuit of a vibrator, which converts the battery current into alternating and rings all the bells. This means no sparking at the bells. Speaking takes place over a metallic pair, the same battery providing the current. The vibrator is with the battery in the office, or other dry place, where it can be got at at once.

The wires should consist of twin 3/22s conductor insulated with pure and vulcanised rubber of 600 megohm grade. It may be armoured or protected against wet if the conditions of the mine demand it. A simple branching joint-box at each 'phone is all that is necessary. The writer knows of at least half a dozen pits in this country equipped in this way, and one of them saves over fifty pounds a year in battery upkeep only.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 30th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

21,354/14. Magnetic Clutches. M. WALKER. A magnetic clutch having two like members divided on a plane midway and normal to the axis of the magnet and of rotation, and an energising coil fixed into a recess in one member, and projecting into a corresponding recess in the other member, by which both members are simultaneously converted into an electromagnet constructed with a friction ring or face of a non-magnetic material between the exterior pole pieces of the members which prevents contact of the faces and obviates the difficulty of remanent magnetism. (Three figures.)

982/15. Fixation of Nitrogen. C. C. MEIGS. An electric furnace for promoting the chemical combination of gases, comprising an outer shell and a closed shell within the outer shell. Contacts carried on the two shells are arranged to slide upon each other to produce "wipe sparks" on rotation. (Three figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Arc Lamps: SAND [Solid metal vapour lamps] 24,766/14.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: HOLMES and BRIEREY [Watertight junction boxes] 20,687/14.

DYNAMOS, MOTORS AND TRANSFORMERS: SIMPSON [Brush holders] 5,672/15.

Ignition: THOMAS TRANSMISSION, LTD., and THOMAS [Ignition] 2,245/15.

Switchgear, Fusings, and Fittings: SCHASCHKE and SHARP [Lamp holders] 23,534/14; MARICANOLA and TESTA [Push and pull switches] 4,012/14.

Telephony and Telegraphy: BRINKMANN [Contact apparatus for telephone systems] 17,863/14; WESTERN ELECTRIC CO. and MACK [Telephone switching] 21,529/14.

Traction: VIDAL [Train lighting] 19,977/14; MIDGLEY and VANDERVELL [Electric engine starters] 24,293/14.

LAW AND ENGINEERING

BEFORE the Society of Engineers on Monday, Mr. Sydney G. Turner read a Paper in which he referred to a number of points of contact between law and engineering. The old controversy of appointing the engineer on a contract as arbitrator in case of dispute was mentioned, and a quotation was made of the words of Lord Justice Bowen in an action between Jackson v. Barry Railway Co., in 1893, to the effect that in appointing the engineer as arbitrator the parties "rely on his professional honour, his practice, and his intelligence; and the contractor certainly has a right to demand that, whatever views the engineer may have formed he will be ready to listen to argument and at the last moment to determine as fairly as he can, after all has been said and heard." In certain cases, however, the Courts have held that the contractor is entitled to be relieved from the arbitration clause. For example, if the engineer himself is a necessary witness at the inquiry, or if the question in dispute involves a consideration of the engineer's own conduct, it is manifestly unfair that he should act as arbitrator.

As an instance of the difficulties encountered in the electrical industry as regards the breaking up of streets and the laying of mains, the author referred to the recent case of the Charing Cross, West End and City Electricity Supply Co. v. The London Hydraulic Power Co., which was decided in 1913. This was an action brought by the Electricity Supply Co. to recover damages for injury to their cables in four different streets, caused in each case by the bursting of the Hydraulic Co.'s mains. The bursting of the mains was not due to any negligence on the part of the defendants, and the question for decision was whether they were under any liability for nuisance. Two of the mains were laid under a private Act which was silent as to liability for nuisance, but the other two had been laid under a later Act which contained a clause to the effect that nothing in the Act should exempt the Company from liability for nuisance. The later Act further provided that the two Acts should be "read and construed together as one Act."

Miscellaneous: DAWSON and BUCKHAM [Electric signalling apparatus] 14,125/14; A.E.G. [Electric driven charging pump for internal combustion engines] 19,492/14; STERLING TELEPHONE & TELEGRAPH Co. and BARCLAY [Mine signalling] 19,854/14; DAY [Electrical coupling devices] 23,212/14; MIDGLEY and VANDERVELL [Lamp signalling arrangements] 3,002/15.

The following Specification is open to Inspection at the Patent Office before Acceptance, but is not yet published for sale.

Ignition: HENNS, 12,248/15.

Opposition to Grant of Patents

Opposition has been entered to the grant of patents on the following specifications:

10,812/14. **Glassware.** GLASFABRIK & RAFFINERIE J. INWALD A.G. Ribbed and prismatic glass reflectors for incandescent lamps.

10,986/14. **Alternators.** SIR C. A. PARSONS. A method of water cooling the rotors of alternators.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: JOHNSON & PHILLIPS and S. PATERSON [Arc lamps] 12,650/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: C. J. BEAVER and C. A. CLAREMONT [Fireproof cable covering] 13,332/04; F. KUHLO [Cable armouring] 13,693/06.

DYNAMOS, MOTORS, and TRANSFORMERS: B.T.-H. CO. (G.E. CO., U.S.A.) [Field magnets] 13,864/04; M. STERN [Control of A.C. motors].

Heating and Cooking: B.T.-H. CO. (G.E. CO., U.S.A.) [Heating elements] 13,961/09.

Incandescent Lamps: B.T.-H. CO. (G.E. CO., U.S.A.) [Filament mountings] 13,590/06.

Switchgear, Fuses, and Fittings: F. T. REID [Time switches] 13,688/07; J. G. MEHNE [Time switches] 14,652/09.

Traction: J. P. TIERNEY [Tramway points] 12,923/08.

Miscellaneous: W. FAIRWEATHER (Brown Hoisting Machinery Co., U.S.A.) [Electric travelling cranes] 13,429/04; J. MCLEAN [Electric hair-brushes, &c.] 13,623/04; SIEMENS BROTHERS & CO., LTD., and F. TURNER [Electric steering gear] 13,567/06; C. A. H., and R. NEWTON [Magnetic separators] 13,845/06; M. SUNDEHEIMER [Burglar alarms] 13,955/09; SIEMENS BROTHERS & CO., LTD. (Siemens and Halske) [Electric signalling] 14,240/09.

It was held that the Hydraulic Co. was liable for nuisance in the case of the two mains laid under the later Act, and further that the effect of the two Acts being read together was to take away any privilege under the earlier Act, and that consequently they were also liable for nuisance in the case of all four mains.

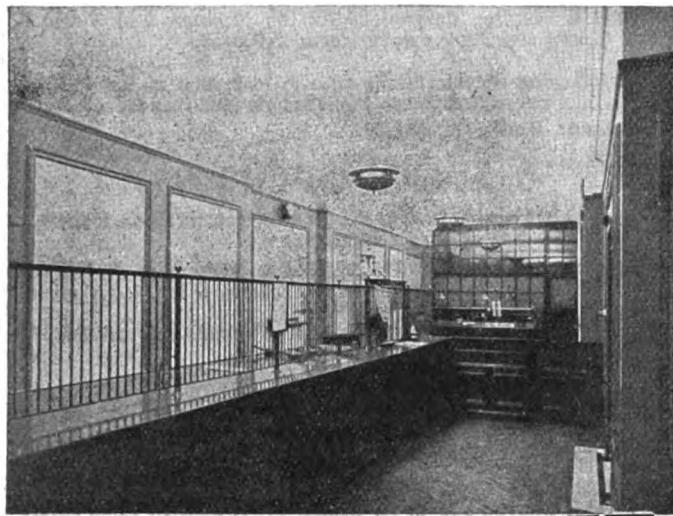

During the course of the discussion, in which several lawyers took part, it was the general feeling that engineers should include, as part of their training, an elementary legal course, in order to acquire the rudiments of the law as it affects their particular branch. There is a possibility of joint meetings between engineers and lawyers being arranged on the lines of the meetings of the Medico-Legal Society.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

According to a Reuter telegram on Thursday last week, the United States Navy Department has successfully experimented with a wireless telephone from Arlington, Virginia, to Mare Island, California, a distance of 2,500 miles. It is stated that the conversation was plainly heard. Successful experiments were also made in telephonic conversation over the regular wire from New York to Arlington, where the conversation was automatically transferred to the wireless apparatus and transmitted to Mare Island instantaneously. A second Reuter telegram adds that, according to officers of the American Telephone & Telegraph Co., wireless communication between the Atlantic seaboard and Honolulu, a distance of 4,600 miles, was accomplished on Wednesday last week. This is in addition to the conversations held under the control of the Naval Department between Arlington and Mare Island.

A LARGE "EYE-REST" LIGHTING INSTALLATION

THE British Thomson-Houston Co. (Rugby) has just completed a lighting installation in which some 120 Mazda "Eye-rest" fittings are employed, in West African House, Kingsway, London. This is a block of offices with a bank on the ground floor, and the illustration of the latter is typical of the other portions of the building. In the bank oxydised silver metal fittings are used, and in the secretary's and agent's offices a single "Eye-rest" fitting with X-ray reflectors has

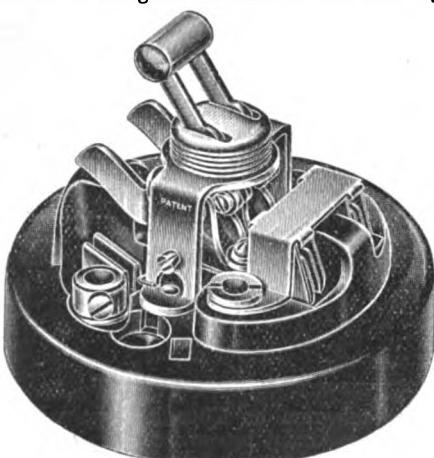

"EYE-REST" FITTING IN MARTIN'S BANK.

been installed. The wiring of West African House was already installed before the details of the illuminating scheme had been determined, and it had been unfortunately arranged that all the lights in each room were turned "on and off by a single switch. To overcome this inflexibility an interesting innovation has been made by providing a three-way pull chain switch in each lighting bowl where required. This pull chain switch constitutes a perfectly unobjectionable addition to the fitting, and permits flexible lighting from each bowl, or permits all the lamps therein to be extinguished, as may be desired.

QUADRUPLE BREAK SINGLE-WAY TUMBLER SWITCHES

MESSRS. A. P. LUNDBERG & SONS (477-489 Liverpool Road, Islington, London), have introduced a new type of single-way tumbler switch with quadruple break, which is designed to obviate the liability of tumbler-switch circuits to somewhat excessive spark-wear due to large voltage or current, or both, or to the inductance of heating apparatus, small motors, &c. At first sight the switch, of which we give an illustration, appears to be identical with the single tumbler double-pole switch made by the firm, but there are essential differences in construction.

SURFACE FORM OF "QUADBREAK" SWITCH. The switch, as its name implies, has four breaks in its circuit. Its normal limit of voltage is 250, and its effectiveness has been amply proved by tests to show that it will easily deal with more than 50 per cent. increase over its rated current capacity if the circuit be not very inductive. If the nominal current be reduced, the switch may be used on circuits at proportionately increased voltages up to 400. The "Quadbreak" switch is made in 10-ampere and 5-ampere sizes, and a flush pattern is made for 5 amperes only. The construction of the switch shows all that careful attention to detail that has characterised Messrs. Lundberg's accessories.

A RECENT EXAMPLE OF "OSRAM" STRENGTH

FROM time to time we have referred, among their other excellent qualities, to the great strength of Osram drawn wire lamps, as evidenced by the way in which they continually stand up to the many severe tests often experienced in practice. The accompanying illustration, reproduced from an untouched photograph, shows a recent example of "Osram" strength. The photograph was sent by a correspondent, who wrote in his covering letter:—

"Enclosed is a photo which I took in the waiting-room at

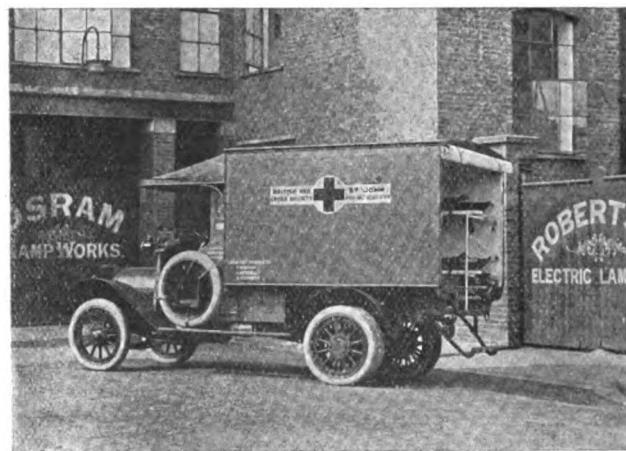

OSRAM LAMP UNBROKEN AFTER FALLING 4 FT.
INTO A HARDWOOD TABLE.

the Mond Nickel Institute, Clydach-on-Tawe. The wire [flex] of the lamp broke, and the lamp and shade fell a distance of 4 ft. on to the wooden table. The shade was smashed to pieces, but the lamp stuck upright in the table, and neither the globe nor the filament was broken; when the photograph was taken it was lighted on another connection."

This incident is but one of many, and serves to show that Osram quality is as good as ever.

OSRAM-ROBERTSON RED CROSS VAN

THE illustration herewith shows the ambulance van presented to the St. John Ambulance Association by the Osram-Robertson Lamp Works. This van is designed to carry eight patients, the driver, and an attendant, and, as will be

noticed, the design of every detail of the equipment conforms to the latest and best practice. The van was photographed outside the Osram-Robertson Lamp Works at Hammersmith, but it is now doing valuable service.

Russian Directory.—The British Engineers' Association has issued a Russian edition of its official directory. The object of the Association originally was to foster trade in China, but an extension of its activities to Russia is opportune, as the openings for trade with that country after the war should be very considerable. The directory contains a guarantee that none of the members of the Association have foreign interests which will be detrimental to Anglo-Russian interests.

CORRESPONDENCE

MAGNESITE.

To the Editor of ELECTRICAL ENGINEERING.

SIR.—We are large buyers of magnesite bricks and dead burnt magnesite, which are used for lining electric kilns for steel-making (basic process).

We cannot find sufficient quantity for our requirements; can you kindly, in your experience, suggest a substitute?

Thanking you in advance,

Yours truly,

VERZOCCHI & DE-ROMANO.

Milan, Sept. 29th, 1915.

[Perhaps some of our readers can give the desired information.—ED. E.E.]

CATALOGUES, PAMPHLETS, &c., RECEIVED

METAL FILAMENT LAMPS.—The latest catalogue of Mazda drawn-wire lamps from the British Thomson-Houston Co., Ltd. (77 Upper Thames Street, E.C.), has a cover with a most effective design in blue, yellow, and orange. The list is well arranged, and includes both ordinary and half-watt Mazda lamps. The distribution of light from a standard lamp is shown by a polar curve.

A.C. AND D.C. OVERLOAD RELAYS.—We have received an interesting and instructive pamphlet from the British Thomson-Houston Co., Ltd. (Rugby), which describes overload relays for alternating and continuous-current circuits. The Type S., Form H., for alternating-current operates on excess current, and may be employed for overload or leakage protection. Type S., Form E., is designed for low and medium pressure alternating or continuous-current circuits for connection in series with the line. Time limit devices can be fitted.

"REVO" ELECTRIC FIRES.—The Cable Accessories Co., Ltd. (Britannia Works, Tividale, Tipton, Staffs.), send us a copy of their new list of "Revo" electric fires, which contain a number of distinct and outstanding features. The principle involved in the heating element is that of an incandescent wire coil in free air, provided with a special heat and light reflector of refractory material. It is claimed that the heat emitted is purely radiant. A number of pleasing designs have been registered.

FERRANTI ELECTRIC FIRES.—A folder from Ferranti, Ltd. (Hollinwood, Lancs.), gives particulars and prices of the firm's bar and cone electric fires. The prices of "spares" are also listed.

The Institution.—The opening meeting of next session of the Institution of Electrical Engineers will be held on Thursday, October 28th, when the President-Elect, Mr. C. P. Sparks, will deliver his Inaugural Address. The usual programme for the session has been arranged, and the necessary Papers have been submitted.

It may interest members of the Institution to know that the electric supply from the generating plant at the Savoy Hotel adjoining, which has been taken since the new Institution building was inaugurated, has been abandoned in favour of a supply from the Metropolitan Electric Supply Co.

Electro Harmonic Society.—The first smoking concert of the season will be held at the Holborn Restaurant on Friday, Oct. 8th, at 8 p.m.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Aberdeen.—In his annual report Mr. J. A. Bell, the City Electrical Engineer, states there is no question but that additional plant will have to be installed by the autumn of 1916-17, and in view of considerable alterations in the engine-room, which can only be done at one period of the year, and the delays in delivery of the new plant, he will deal with the subject in a special report at an early date.

Australia.—The Sydney Council requires some 33,000-volt three-phase transformers and switchgear, together with spares. Preference will be given to British manufacturers, and a copy of the specification may be seen at 73 Basinghall Street, E.C.

Barking.—The L.G.B. has sanctioned a loan of £13,654 for extensions of plant, mains, &c.

Darwen.—An application is to be made for sanction to a loan of £3,000 for mains and services.

Dublin.—The Corporation has decided to make a number of connections for which applications were made prior to the receipt of the Treasury notice as to restricting capital expenditure. Any further applications are to be submitted to the Treasury for approval.

Littleborough.—H.T. cables, transformers, and switchgear. Consulting Electrical Engineer, W. C. C. Hawayne, 9 Queen Street Place, E.C. Tenders to Clerk. October 22nd.

London: Hammersmith.—The Electricity Department requires a supply of air-cooled static transformers. Borough Electrical Engineer. October 14th. (See advertisement on another page.)

South Africa.—The Pretoria Corporation has decided to raise a loan of £75,000 in connection with electric supply.

Watford.—A loan of £1,560 for mains is to be applied for.

Wiring

Watford.—Lighting and power installation at pumping station. Borough Engineer. October 18th.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Bingley.—Fire brigade station.

Darlington.—Institute in Skinner Street.

Newcastle-on-Tyne.—Rebuilding of N.E.R. No. 3 warehouse at Tyne Dock. Architect, Arthur Pollard, Irving House, Westgate Road.

Miscellaneous

Australia.—The Deputy Postmaster-General, Sydney, requires 100 miles of two-twisted and 75 miles of three-twisted copper wire. Further particulars at 72 Victoria Street, S.W. November 4th.

Birkenhead.—The Mersey Railway Co. requires electrical sundries. General Manager, Central Station. October 14th.

British Columbia.—The High Commissioner for Canada, 19 Victoria Street, S.W., has an inquiry from Victoria for half-watt lamps.

London: L.C.C.—Electric lamps are required for the Council's various asylums. Clerk, Asylums Committee, 6 Waterloo Place, Pall Mall, S.W. October 15th.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

The Mirless Watson Co., Ltd., of Glasgow, have received, among others, orders for condensing plants from the following:—The Scottish Central Electric Power Co., the St. Helens Corporation, Société Anonyme Westinghouse, North Lonsdale Iron Co., Rossington Main Colliery, and Greenwood & Batley. Orders for Edwards air pumps from Compagnie Française Thomson-Houston.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £87 10s. to £88 10s. (last week, £87 to £88).

Change of Address.—The Swedish General Electric, Ltd., has now moved into more commodious offices at Canada House, Kingsway, W.C., to which address all inquiries should be sent.

The Late Phoenix Electric Heating Co.—The Dowsing Radiant Heat Co., Ltd., having purchased the useful stock comprising electrical fittings for repair of electric heating and cooking apparatus from the late Phoenix Electric Heating Co., of 17 Morwell Street, W.C., beg to advise the trade that they would be pleased to execute any repairs or supply apparatus previously manufactured by this firm.

Australian Agency.—A Sydney firm wishes to take up agencies of United Kingdom manufacturers of electric lighting sets for motor-cars and electrical fittings, lamps, and sundries. Further particulars at 73 Basinghall Street, E.C.

County of Durham Electrical Power Distribution.—It has been decided not to declare an interim dividend on the preference shares.

Lancashire Dynamo & Motor Co.—An interim dividend at the rate of 6 per cent. per annum is declared on the ordinary shares for the past half year.

APPOINTMENTS AND PERSONAL NOTES

Mr. R. W. L. Phillips, Borough Electrical Engineer at Bedford, has been granted 50 guineas for work done in preparing specifications for and supervising the wiring of the isolation hospital, education committee buildings, &c.

An Overhead Linesman is wanted by the Swindon Electricity Department. (See an advertisement on another page.)

Two Switchboard Attendants are wanted by the Harrogate Electricity Department. (See an advertisement on another page.)

LOCAL NOTES

Bedford: *Relief of Rates.*—Out of the profits made on the electricity works last year, the sum of £2,000 has been transferred to the relief of rates. The gross profit was £13,225, and the balance is represented by interest and capital charges, and £1,610 transferred to reserve fund.

Belfast: *Munition Workers Summoned.*—The local Munitions Court last week fined an electrician 20s. for leaving work at a munitions factory for some hours without authority.

Brighton: *Electricity Deficit.*—In connection with the recent recommendation to increase the charges as mentioned in our last week's issue, Mr. J. Christie, the Borough Electrical Engineer, estimates that coal will cost the Department £8,000 more this year than the already heavy amount paid last year. A heavy loss will also arise through the reduced public lighting. It is calculated that the increased charges which came into operation at the beginning of April will reduce this loss to £5,450, whilst the further increase now recommended will reduce it by a further £4,000.

Cardiff: *Electricity Accounts.*—Satisfaction was expressed at the last meeting of the Corporation with the accounts of the electricity undertaking for the past completed year. The

total income was £3,640 more than in the previous year, whilst the expenditure increased by £1,627. The net result of the year's working was a profit of £5,924, which it is proposed to carry forward.

Colchester: *Electricity Accounts.*—There was a net profit of £813 for the year to March 31st, 1915, compared with £649 in the previous twelve months. Up to Christmas, 1914, it is pointed out that the average price of coal, excluding cartage, was approximately 14s. per ton, whereas at present it is about £1 per ton. Unless, therefore, some unforeseen decrease occurs, there is, it is pointed out, a likelihood of fuel costing about £1,500 more during the current year than last year.

Dublin: *Munition Workers Fined.*—A number of workmen employed by a firm of Dublin electrical engineers engaged on munitions have been fined £1 each for going on strike. The men are still out, and it was stated that warrants for the recovery of the penalty will not be issued for seven days. If within that time the parties come to an agreement, the Chairman of the Court intimated that he would recommend the authorities to remit the penalties.

Fleetwood: *Increased Charges.*—The charges for electric current are to be increased by 10 per cent. The increase, however, will not apply to current consumed through pre-payment meters.

Glasgow: *Inspection of New Electricity Works.*—The members of the Corporation inspected on Friday the preliminary work which has been carried out upon the new Dalmarnock electricity works. Owing to prevailing conditions it is probable that the main work of installing the plant will be considerably delayed, and for the moment all that was available for inspection was the foundations of the turbine-room and boiler-houses and the elaborate arrangement for the intake of water from the Clyde. In this connection six screens have been constructed, each capable of purifying 50,000 gallons of water per minute.

New Electricity Showroom.—The Electricity Department, in conjunction with local wiring contractors, has opened its showroom at 257 Sauchiehall Street. In our issue for March 25th, p. 128, we gave the terms of the arrangement which has been come to between the Department and wiring contractors with the object of avoiding the unfortunate controversy which has existed for so long, and still exists in some parts, between wiring contractors and municipalities who prefer to carry out wiring work independently.

India: *Simla Extensions.*—According to the *Times of India*, the Simla hydro-electric installation has proved so successful that considerable extensions have been decided upon. It is intended to instal a 500-kw. generator with turbine and two 250-kw. transformers with necessary switchgear. The necessary steel piping for dealing with the head of water has already been received, as also have the switchgear and transformers. The turbine is on its way, and the generator is expected by the middle of November.

Newcastle-on-Tyne: *New Tariffs.*—With reference to our Note last week, the Newcastle-on-Tyne Electric Supply Co. and its associated companies have introduced two new tariffs known as the "domestic" and "office" tariffs respectively. Under the first-named the consumer pays a fixed charge on the lighting installation on the basis of 6s. per lampholder per annum. The charge, however, is made on only 75 per cent. of the total lampholders installed, but the tariff is conditional upon the consumer installing electricity for lighting purposes throughout. The fixed charge is payable in full for the first year, and in subsequent years one-third for each winter quarter and one-sixth for each summer quarter only is paid. The charge per unit above this is 1d. without meter rents. The office tariff is an alternative to the flat rate of 1½d. per unit for heating purposes. The consumer pays a fixed charge of 10s. each winter quarter and 5s. each summer quarter, irrespective of the capacity of the lighting or heating installation. The charge per unit in addition is 1d. for heating, lighting being charged at the ordinary standard tariff. All classes of electrical apparatus is hired as it has been done in the past.

South Shields: *Electricity Profits.*—There was a net profit of £3,216 on the working of the electricity undertaking for the year to March 31st, 1915. From this £1,600 are to be contributed to relief of rates and the balance to reserve fund.

Sutton Coldfield: *Loan Refused.*—The L.G.B. has refused to sanction a loan of £2,500 for a new generating set.

Yarmouth: *Increased Charges.*—The Electricity Committee has decided to increase the charge for private lighting from 5d. to 5½d. per unit, and to withdraw the discounts at present allowed in respect of power supply.

SUMMARY

DETAILED instructions have been issued in Germany as to the electrical accessories and their parts, in which zinc or iron is to be substituted for copper or brass, and the permissible current densities stated. The list includes lampholders, lamp caps, and cable lugs (p. 414).

THE position with regard to the E.C.A. Guaranteed Wiring Scheme is stated (p. 414).

AN appeal is made for recruits for the London Electrical Engineers (Territorial Force) (p. 414).

THE subject of scientific and industrial organisation to meet German commercial competition after the war was dealt with by Professor J. A. Fleming, in a lecture at University College last week (p. 414).

THE large system of the Shropshire, Worcestershire and Staffordshire Electric Power Company has developed to such an extent that the plant capacity had to be increased by 10,625 kw. during the past 12 months. We describe the additions to the plant and the system generally. A feature is the excellent diversity factor, resulting in a load curve practically without a peak (p. 415).

A COMPACT and well-designed $\frac{1}{2}$ kw. petrol-electric set to run without a battery is described on p. 417.

A MULTIPLE lever starting switch is described on p. 418.

MR. A. H. Dykes, in his Presidential Address to the Association of Supervising Electricians outlined a scheme of apprenticeship in the electrical trade (p. 418).

OUR Questions and Answers page describes a convenient workshop method of obtaining a variable frequency for testing purposes (p. 419).

THE opening of the I.E.E. session has been postponed to Nov. 11th (p. 419).

AMONG the subjects of specifications published at the Patent Office last Thursday were electric driven charging pumps for internal combustion engines, train lighting, vapour lamps, and signal lamps. A metal filament patent is opposed (p. 420).

NOTWITHSTANDING street lighting restrictions and other detrimental causes due to the war, the Stepney electricity undertaking made a profit of £10,702 last year. Moreover it has not been found necessary to increase the pre-war tariff (p. 420).

THE difficulties encountered in wireless telegraphy from aeroplanes and airships were discussed by Prof. Fleming, at University College, last week (p. 421).

EXTENSIONS estimated to cost £6,000 are to be undertaken at Wigan; new plant is required at Rotherham, and a telephone switchboard and paper-insulated cable in Australia.—Attention is drawn to the market for electric lighting and power plant in China (p. 421).

IN spite of opposition, the Edinburgh Corporation has decided to proceed with the equipment of the new Portobello power station.—An apprenticeship scheme has been devised in the Marylebone Electricity Department.—There is discontent on the part of some members of the Oldham electricity staff (p. 422).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D.,
COMMANDANT.

Drills, 6.30 to 7.30; 7.30 to 8.30.

(To-day) Thurs., Oct. 14th: Section III., technical. Section I., shooting.

Fri., Oct. 15th: Section IV., technical. Section II., squad, signalling class.

Mon., Oct. 18th: Section I., technical. Section IV., squad.

Tues., Oct. 19th: Section II., technical. Section III., shooting.

Thurs., Oct. 21st: Section III., technical. Section II., shooting.

Fri., Oct. 22nd: Section IV., technical. Section I., squad.

Signalling class Mondays and Fridays, but members will attend technical classes Mondays and Fridays with their Sections.

Recruits attend on Mondays and Fridays.

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682), and the Drill Centre is at the H.Q. of the London Electrical Engineers, 46 Regency Street, S.W. (by kind permission of Lt.-Col. A. E. Le Rossignol).

Members will fall in for all drills at the new headquarters, Chester House, Eccleston Place, S.W., on and after Monday, October 18th.

General Sir O'Moore Creagh, V.C., G.C.B., G.C.S.I., has appointed Mr. R. W. T. Corbett and Mr. Hughes-Hallett Platoon Commanders.

Mr. Corbett will take charge of Nos. 3 and 4 Sections and will also superintend the musketry for the Company.

Mr. Hughes-Hallett will take charge of Nos. 1 and 2 Sections and also the signalling.

Mr. J. W. Roger promoted Section Commander No. 4; Mr. H. de P. Birkett promoted Section Commander No. 3; Mr. P. F. Allen promoted Section Commander No. 1; and rank in seniority in above order.

THE GERMAN COPPER FAMINE

THE *Elektrotechnische Zeitschrift* of September 23rd contains some new and very specific instructions, issued by the Verband Deutscher Elektrotechniker, as to the electrical apparatus and parts hitherto made of copper and brass for which iron or zinc are now to be substituted in Germany. In order to save copper, this notice says, it is *absolutely necessary* to use iron or zinc instead of copper in every instance in which it is possible, even at the expense of goodness and life of the article in question.

Makers are warned as to obvious precautions to be taken, for instance, to prevent iron contacts from rusting, by galvanising or lead-covering them, or by "expert greasing," or proper enclosure. Owing to the very diverse properties of the various qualities of zinc obtainable in the trade, it is necessary to be particularly careful in the selection of this metal, and it is also essential to bear in mind its low tensile strength and elasticity, its low melting-point, and also its sensibility to both high and low temperatures. The following articles, it is said, can be made out of iron and zinc:—

Bells. Bearing "brasses." Terminals. Bus Bars and Connections on Switch- and Distribution Boards; these may be of solid iron for D.C. for any current, but for A.C. suitable precautions must be taken. Switches of all classes; from 25 to 100 amperes all parts, with the exception of the spring contacts and the surface taking the actual break, can be of iron or zinc, but this latter exception does not apply in the case of switches with no spark at break, e.g., isolating switches, &c.; connecting bolts and terminals may be of iron.

Plugs and Sockets up to 25 amperes can have all parts made of iron or zinc which have hitherto been made of copper or its alloys, but the actual plugs should preferably be made of iron and not zinc. Over 60 amperes the plugs must be copper or brass, but the other parts can be made of iron or zinc.

Enclosed Fuses: All parts of the fuse-holders hitherto made of copper or brass can be made of iron or zinc with the exception of the screw sockets stamped out of sheet metal for over 60 amperes; all parts of the cartridges hitherto of copper and brass can be replaced by iron or zinc except the connection pieces for the fuse and threaded part which is stamped out of sheet metal for over 60 amperes.

Open Fuses up to 350 amperes need have no copper or brass parts except the spring clips of the fuse-carriers.

Lampholders and Lamp Caps: All parts can be made of iron or zinc instead of copper.

Starters and Regulating Resistances: Up to 100 amperes all copper and brass parts can be replaced with iron or zinc except the end contact which takes the arc; iron or a suitable iron alloy is to be used for the resistances.

Cable Lugs: Up to 35 sq. mm., iron can replace copper or its alloys without change of dimensions; for larger sections iron can also be used, but at lower current rating; special attention must be given to the soldering.

Fixing Screws must be iron, unless a non-magnetic material is necessary on account of eddy current or magnetic conditions.

Tables are also issued of the dimensions of iron and zinc wires, bolts, and bus bars for different currents. Zinc wires are rated at nearly double the section of copper for the same current, and iron wires about $2\frac{1}{2}$ times. Thus a 1.5 sq. mm. copper wire may carry 14 amperes, and a zinc wire of this size 9 amperes. At 2.5 sq. mm. the maximum current is 20 amperes for copper, 11 for zinc, and 8 for iron, and the permissible current densities gradually decrease up to 150 sq. mm., for which the permissible current in copper wires is 325 amperes and in zinc wires 170 amperes. Iron conductors are apparently only contemplated between 2.5 and 16 sq. mm., the latter size to carry 30 amperes. The current densities, therefore, range from about 6,000 to 1,400 amperes per sq. in. for copper, 3,870 to 730 amperes per sq. in. for zinc, and between 2,060 and 1,200 amperes per sq. in. for iron over the range of sizes mentioned.

The E.C.A. Guaranteed Wiring Scheme.—With reference to an article last week referring to the Board of Trade objections to the Electrical Contractors' Association guaranteed wiring scheme, we understand that at a special meeting held at Leicester on Wednesday last week a Committee was appointed to deal with the position.

A Heating, Lighting, and Cooking Exhibition.—The Institute of Hygiene held an exhibition of heating, lighting, and cooking at its building in Devonshire Street, W., from Oct. 4th to 9th. Although on a small scale, the installation was very complete, and showed the application of electricity and other forms of power to various purposes. During the run of the exhibition, a number of lectures were delivered, including one by Mr. L. Gaster on "The Use and Abuse of Lighting."

LONDON ELECTRICAL ENGINEERS (TERRITORIAL FORCE)

Appeal for Recruits

RECRUITS are wanted for the London Electrical Engineers (Territorial Force). This Corps was the first engineering unit formed in the British Army to make use of the services of electrical engineers. It was first started as the Electrical Engineers (Volunteers) in the year 1897 by the late Dr. John Hopkinson, and the name was changed to the present title on the formation of the Territorial Force. Numerous other units utilising the services of electrical engineers have since been formed, but the largest unit is still the London Electrical Engineers.

Owing to the expansion of the Corps, the opportunity now exists for men of suitable age and training to enlist in the unit. Men of the following professions and trades are specially required: Electricians, Mechanical and Electrical Engineers, Engine Drivers, Engine Erectors, Instrument Repairers, Metal Turners, Fitters, Telephonists and Telegraphists. There are a limited number of vacancies for Carpenters, Cabinet Makers, Pattern Makers, Draughtsmen, Joiners, and Wood Turners.

Forms of particulars can be obtained from the Officer Commanding at 46 Regency Street, Westminster, S.W.

The Electrical Engineers (Volunteers) Corps saw active service within three years of its formation, a draft of five officers and forty-seven men taking part in the South African War in 1900, under the command of Lieut.-Col. R. E. Crompton. That was, of course, before the days of high explosives, and many of the uses to which engineering in general, and electrical engineering in particular, are now being put on the various fighting fronts, and which are regarded as commonplace, were distinctly novel during the South African War. The present fighting has been characterised as a telephone war, and it is instructive to note that the plain uninsulated wire now used for telephone purposes for short distances was also used by the Electrical Engineers (Volunteers) South African Detachment, a part of the equipment consisting of bicycles fitted with wire-drums. Indeed, it may be said that the splendid work carried out by the Corps in South Africa furnished the starting-point for many applications of mechanical and electrical engineering to military operations.

SCIENCE ORGANISATION

PROFESSOR J. A. FLEMING, F.R.S., in his lecture at the University College, London, on Wednesday last week, to which reference is made in Telephony and Telegraphy (including Wireless), dealt incidentally with the need for the proper organisation of science and industry immediately, if we are not to be put once more, after the war, under the same domination of German influence commercially as we have been in the past. He complained, however, that although the Royal Society had appointed a number of committees to examine the engineering, mechanical, and chemical aspects, no information had been given to the public as to the constitution of these. He believed the object of this unusual secrecy was to prevent correspondence from eager inventors, but he hardly regarded this as a valid argument, because the names of other committees appointed by the Admiralty and the Ministry of Munitions were known, and no inconvenience had been experienced. The important qualifications of members of committees such as these should not be merely scientific or theoretical, but they should have a sufficient practical knowledge of the matters to be considered. The men who used the things were those who should be able to give the best information. It was impossible to judge an invention by a written description, and although this meant expense, efforts should be made to test on a practical scale schemes put forward, after due consideration of their possibilities. He contrasted the pooling of research work in Germany with the jealousies of British manufacturers, and urged that a disciplined army of scientific workers is badly wanted in this country. By comparison with a military army, our scientific army was a mob of civilians armed for war with shot-guns and sticks. Probably the best solution would be to place the whole scientific organisation of the country from every point of view in the hands of the British Association.

Another question which should be taken up was the use of coal as a means of producing the electrical energy necessary to manufacture atmospheric nitrogen and its compounds. In this connection Professor Bottomley, of King's College, had made a number of enormously important discoveries. For instance, he had discovered that peat treated in a particular way electrically could be made into a fertiliser containing fifty times more value than manure.

A POWER COMPANY WITHOUT A PEAK

THE Shropshire, Worcestershire & Staffordshire Electric Power Co., which is associated with the Birmingham & Midland Tramways Joint Committee, has been developing quietly during the past ten years, and is now one of the most important electric power companies in this country. After the completion of some extensions in the power-house this year, we asked for permission to inspect it, and through

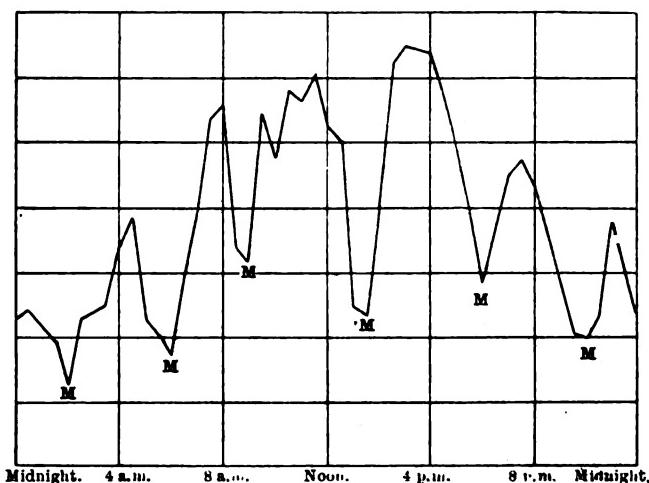

FIG. 1.—TYPICAL LOAD CURVE. M = Meal-times.

the kindness of the Chairman and Mr. J. H. Legge, the Chief Engineer, we are enabled to publish a description of the station and the system generally.

The mains cover an area of about 14×12 miles, and include the districts of Smethwick, Oldbury, and Halesowen (which adjoin Birmingham on the west and south-west), and Dudley; and in addition to the power supply to works, the Company

Fig. 1, which shows that it has no pronounced peak at all. The consumers include about a dozen rolling mills, which in themselves represent nearly half the total load on the station in spite of the large diversity factor which rolling mills always afford; the largest is a mill rolling strip for tubes, and has a 3,000-h.p. motor, taking supply at 5,500 volts, and with a power-factor of 0·78. This is probably the largest motor on any power company's mains in the United Kingdom. Another rolling mill on the Company's mains has a 1,800-h.p. motor. There are several electric welding plants connected to the mains, particularly for welding steel tyres; these range from the heaviest section (one plant for 80 pairs taking 120 kw.) down to cycle-rims. Many chemical works also take power from the Company, and large numbers of general engineering works, including those for the manufacture of lighter articles with automatic machinery, which is, of course, one of the staple industries of the districts near Birmingham. The total connections represent some 22,000 kw., of which about 2,000 kw. is for lighting and 1,500 kw. for tramways; the above lighting total includes Dudley, whose Provisional Order was taken over by the Company from the Dudley Corporation last year, as well as Oldbury, Smethwick, and Halesowen, for which towns the Company also owns Provisional Orders.

The total plant capacity at the Smethwick power-house is just over 17,000 kw., and the supply is at 5,500 volts three-phase 25 cycles per sec. In addition to this, the Dudley power-house taken over from the Corporation has a capacity of 1,600 kw. in D.C. plant, supplying both lighting and tramways, but this station is to be gradually reconstructed and existing reciprocating sets taken out; a 2,000-kw. turbo-alternator set is already being put in, which will run in parallel with the Smethwick plant. Meantime, a 1,100-kw. rotary converter sub-station has been completed at Dudley, in the centre of the town. At Smethwick the plant is made up of the following units:—A 6,250-kw. Brush-Dick-Kerr turbine set, a 4,375-kw. B.T.-H. turbine set, one 2,000-kw. and two 1,000-kw. Brush-Brush turbine set, and three 500-kw. Brush-B.T. H. reciprocating sets (now used only as stand-by). Besides these, there are three 300-kw. and one 100-kw. D.C.

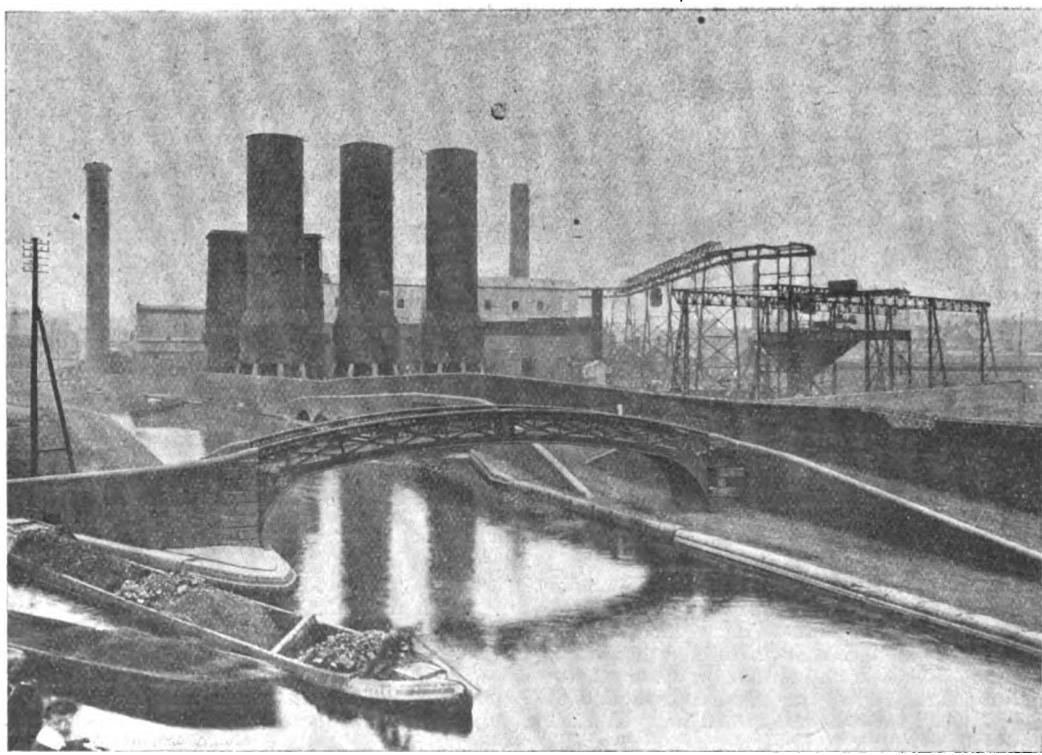

FIG. 2.—GENERAL VIEW OF SMETHWICK POWER HOUSE.

also supplies the tramways managed by the Birmingham & Midland Tramways Joint Committee, viz., the Birmingham District Power & Traction Co., the Dudley, Stourbridge & District Electric Traction Co., the South Staffordshire Tramways, and the Wolverhampton District Electric Tramways. The power supply has developed to such an extent, however, that, in spite of the trams covering a track mileage of 97 and a route mileage of $65\frac{1}{2}$, they represent a comparatively small portion of the load. An idea of the character of the load may be gained from the typical load curve shown in

sets supplying at 500 volts for the tram circuit fed direct from the station, and the station auxiliaries and lighting; two 310-kw. rotaries in the station are also available for this.

It is the 6,250-kw. and the 4,375-kw. sets that have been put in during the past twelve months. The Brush-Dick-Kerr set occupies a floor-space of only about 36 ft. \times 12 ft. with its exciter; its condenser, circulating and air pumps, and a blower for ventilating the generator are in the basement immediately beneath. The turbine is of the pure reaction type. A feature is that the bed is an independent casting:

the cylinder simply rests on bored seats and is held down by its own weight, with a stop to prevent it from rotating. This arrangement is to allow for expansion without undue stresses being set up in the casing. The bearing shell at the exhaust end is prevented from moving axially by means of a strong rib engaging in a groove in the bed-plate seating, while the bearing shell at the other end is free to slide axially. For the high-pressure part of the casing a steel casting is employed, and the remainder is of close-grained cast-iron. About one-quarter of the full output is developed in the high-pressure part, which has four groups of copper blades; the intermediate and low-pressure parts have brass blades and develop a quarter and half the total power respectively. The length of the blades varies from 1 to 10 inches, and lacing strips are silver-soldered to the tips to prevent vibration. To provide for overloads, the first two of the four groups of high-pressure blades are by-passed automatically as soon as full load is reached. The governor is of the centrifugal type, driven through helical gearing from the rotor spindle, and, in addition, there is an emergency governor which closes the stop and emergency valve as soon as the speed is 10 per cent. over normal.

ventilating ducts. The end bells and discs are of manganese-bronze, and the latter are a force fit on the shaft.

The 4,375-kw. B.T.-H. set is of the standard horizontal shaft Curtis pattern, both as regards turbine and alternator. The turbine is five-stage, and the alternator a two-pole machine with a direct-coupled exciter.

So far as the remainder of the engine-room equipment is concerned, the most interesting feature is the switchgear for the new plant, which is of the latest B.T.-H. pattern in stone cubicles with iron doors. The sections of the board are separated by reactances placed in a separate fireproof chamber, and B.T.-H. machine-protective gear is employed and aluminium lightning arresters.

The boilers are of the ordinary Babcock-Wilcox land type with natural draught; bunkers over them can take 2,000 tons of coal, and there is also a big fuel store in the yard. Induced draught plant is being put in for the new boilers. As the station is on the junction of three canals, most of the coal comes in the Company's own canal-boats, but a little is road-borne. A trolley coal and ash conveyor of Messrs. Robert Dempster & Sons' make is employed, capable of dealing with 40 tons an hour. Make-up feed water is obtained from an

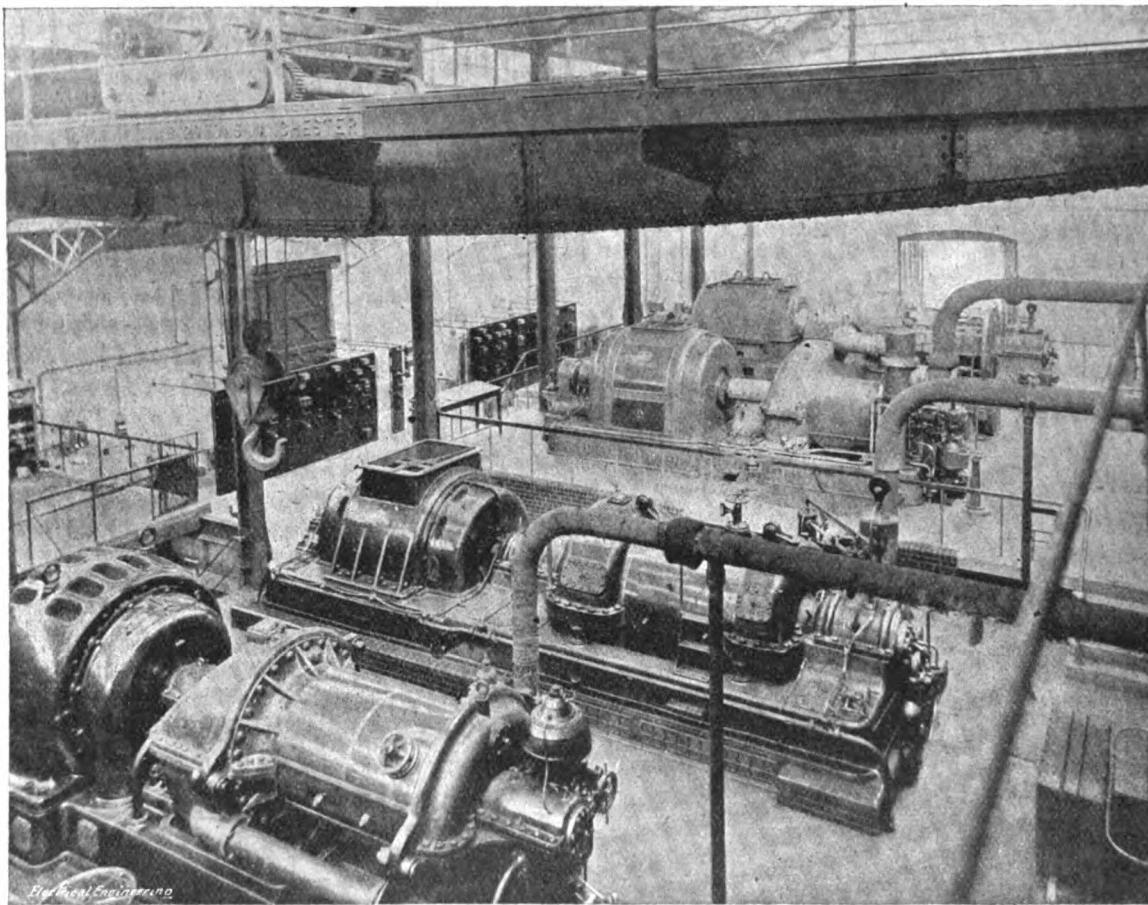

FIG. 3.—ENGINE ROOM OF SMETHWICK POWER HOUSE.

The condenser has 13,250 sq. ft. of heating surface; its tubes are $\frac{1}{4}$ in., and there is 11 ft. 10 in. between tube plates. It is bolted direct to the flange of the turbine exhaust pipe, and expansion is provided for by mounting the condenser on springs.

The speed of the set is 1,500 revs. per min., and the generator is therefore two-polar. It has the usual construction of Messrs. Dick, Kerr & Co.'s turbo-alternators of the cylindrical rotor type. The cast-iron stator frame consists of two shells with a space between them, the outer portion being provided with a chimney-type opening. The end shields are open at the bottom, and air is blown in there and passes through the hollow stator. Pure mica insulation is employed for the copper bar windings of the stator, which are wound in nearly closed slots; in addition, there is an outside protection of leatheroid. The end windings are former-wound, and supported by substantial bronze brackets bolted to the stator end rings. The rotor and shaft are formed of one steel forging. Open longitudinal slots are machined in the body to receive the field windings, which are held in place by manganese-bronze wedges, and there are longitudinal ventilating holes through which the air is blown and discharged through slots placed at intervals to correspond with the stator

artesian well, but part of the make-up circulating water is taken from the canal. For cooling the circulating water there are three Worthington natural draught steel cooling towers, with a collective capacity of 500,000 gallons of water per hour from 100° to 80° F., also a wooden Sylverlast cooling tower of 290,000 gallons per hour capacity. The Worthington towers are estimated together as sufficient to deal with 86,000 lb. of steam for a vacuum of 27½ in. Each has a shell 28 ft. 8 in. diameter, a chimney 22 ft. 8 in. diameter, and a height of 100 ft. The water is discharged by a stand-pipe through a distributor, which revolves by the impulse received and distributes the water over a filling of cylindrical galvanised steel sheets.

So far as the distribution of power over the area is concerned, the system differs from those of the majority of power companies by the load being fairly thickly and evenly distributed, so that it has been found expedient to distribute at 5,500 volts as well as to transmit at this pressure. Ring mains are chiefly used, but in some cases duplicate feeders, and a few of the spares are also in duplicate. For the most part the cables are paper-insulated lead-covered, and drawn into stoneware ducts, but a little is laid on the solid system and there

is a short length of overhead. The biggest E.H.T. cable is 0.25 sq. in. In some parts subsidences have had to be provided against, and the precaution employed has been simply to leave slack in the draw-in boxes. Among the consumers are several rotary converter sub-stations, many of which are running in parallel with existing private generating plants; in some instances the private plants have been gradually displaced in this way. The Company has its own rotary converter sub-stations at Smethwick (600 kw.), Dudley (1,100 kw.), Oldbury (600 kw.), and Tividale (300 kw.), all supplying partly lighting and power and partly traction. At Halesowen the lighting under the Company's Provisional Order is supplied by a static transformer sub-station, with secondary on the four-wire system—lighting 110 volts, and power 190 volts. Although, as has been said, there are many private rotary converter sub-stations, the majority of the works supplied use three-phase current, and have their own sub-stations, while practically all the rolling mills take three-phase supply at 5,500 volts right on to the motors. It would have been interesting to complete this article with descriptions of the plant and methods of electric power distribution at some of these works, but the activity which prevails in all of them at present precludes us from doing so.

THE "UNI-LECTRIC" LIGHTING PLANT

WE have been very favourably impressed with a compact and well-designed petrol-electric set for lighting small houses, &c., recently shown us by Messrs. Walter D. Fair & Co. (43 Leicester Square, W.C.). It is a high-speed set with shunt dynamo and automatic voltage regulation, and as the speed is about 1,950 r.p.m. and the engine a four-stroke machine, this corresponds to about sixteen explosions per sec., so that, as the machine has a heavy flywheel, there

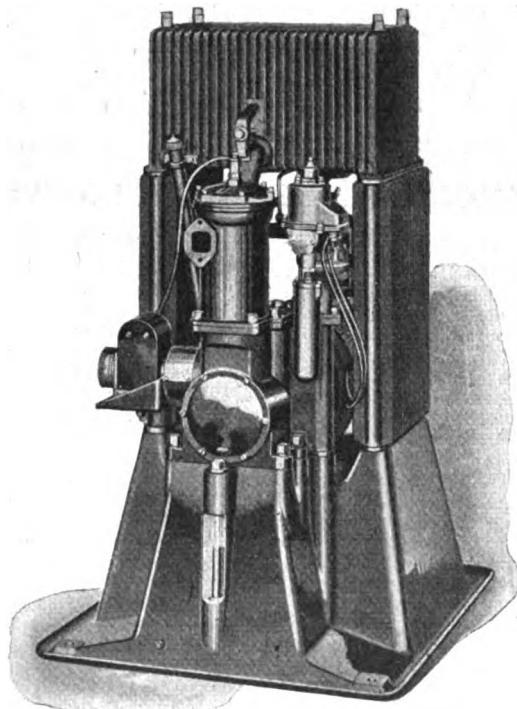

FIG. 1.—"UNI-LECTRIC" GENERATOR SET.

is no perceptible flicker of the lamps, and the set is intended for use without a battery. It is made in one standard size, viz., $\frac{1}{2}$ kw. at 110 volts. Its dimensions are 24 x 22 in. x 39 in. high, and its weight 365 lb.

Figs. 1 and 2 show the general design of the set, and Fig. 3 the generator. This latter, it is seen, is a two-pole machine, and a feature of it is that it is air-cooled by fan-blades on the flywheel; the cooling air is also directed on to the fins on the inner sides of the engine radiator columns. For voltage regulation a simple solenoid and plunger arrangement is provided, acting on the throttle of the engine. The plunger, which is vertical, has a rod attached to it, at the bottom of which is a wooden float in a mercury bath. The upward thrust of the mercury exactly balances the downward pull of the solenoid on the plunger at 110 volts; the solenoid is, of course, simply shunted to the terminals of the generator. At about the centre of the rod is a small rack, which meshes with a pinion and opens or closes the throttle valve according as the rod moves upwards or downwards. Thus it is seen that the voltage is simply regulated by altering the speed of the

engine, which varies from about 1,500 r.p.m. at no load to 1,950 at full load.

Both engine and generator are of American manufacture, the former by the Waterman Motor Co., of Detroit, and the latter by the Wagner Electric Manufacturing Co., of St. Louis.

The base of the engine is a single casting with three compartments. The compartment under the crank-case of the motor forms a reservoir for the lubricating oil, with a capacity sufficient for several weeks' running under ordinary service conditions. A compartment at the opposite end of the base forms with the radiator columns and the tank which

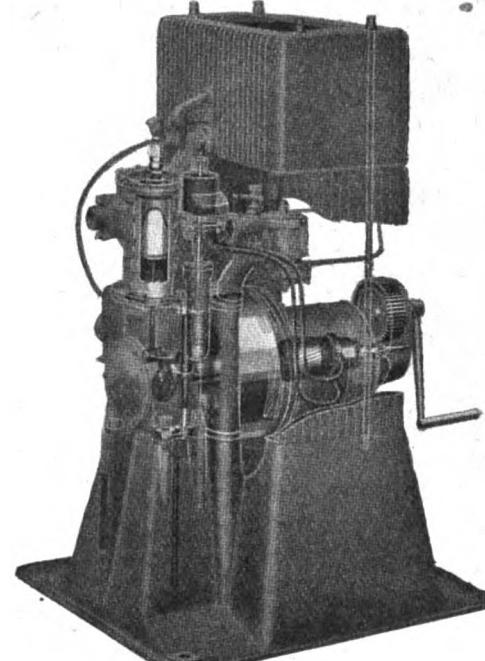

FIG. 2.—"PHANTOM" VIEW OF SET.

surmounts them, a water reservoir with a capacity sufficient for many days at a moderate atmospheric temperature. This water reservoir connects above and below with the water-jacket of the motor cylinder, giving a good thermo-syphon circulation of the cooling water, while the intermediate compartment forms a muffling chamber for the carburettor intake. The fuel tank is mounted below the generator, and connected through an automatic vacuum feeder to a specially designed carburettor. Ignition is by high-tension magneto with fixed spark. Lubrication is provided by an automatic pump in

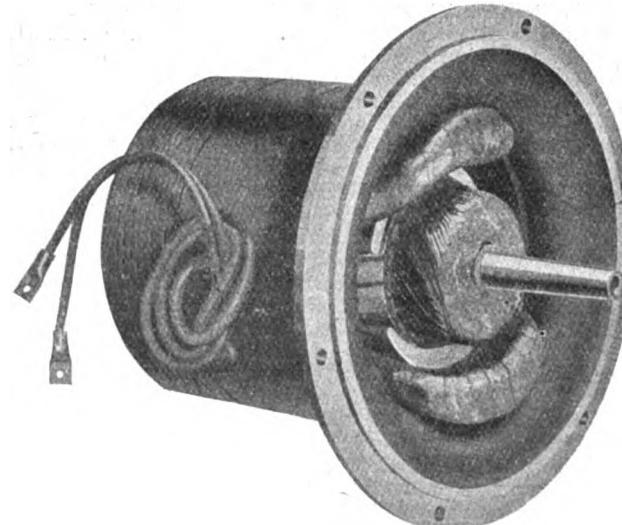

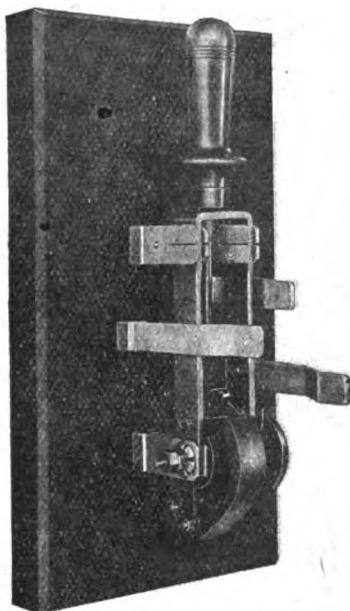

FIG. 3.—THE GENERATOR.

the oil reservoir, delivering the lubricating oil to all friction surfaces. The motor is of the silent sleeve valve type, and the exhaust has a specially large and efficient silencer. All moving parts are enclosed. The engine is started by a simple high-gearied crank, automatic in engagement.

Mr. A. B. Rigby, who showed us the set, informs us that he will be pleased to give further information to any electrical contractors who are interested in it, and has a set on view at the Company's offices at the address mentioned at the commencement of this article.

MULTIPLE CONTACT LEVER STARTING SWITCH

A NEW list issued by the British Thomson-Houston Co., Ltd. (Rugby), describes lever-starting switches of the knife pattern, specially designed for starting large continuous-current motors. They are of the multiple contact double-blade type, and are made in various sizes up to 1,000 amperes capacity.

400 AMP. 4-POINT SWITCH WITH SLOW MOTION DEVICE.
(Closed position.)

The switch can be fitted with a slow motion device, which ensures positive stopping on each contact. When this attachment is fitted, the handle is separated from the switch blade, the latter being actuated through a simple mechanism near the hinge, consisting of a pawl and pin wheel. A guard over the pin wheel lifts the pawl out of action when it passes over more than one pin. Thus each forward motion of the handle drives the pin wheel one step forward. The switch blade thus stops positively on each contact, and, as the motion of the handle has to be reversed in order to engage with the pin wheel for the next step, it is impossible to close the switch without stopping on each contact.

AN ELECTRICAL APPRENTICESHIP SCHEME

A Suggestion by Mr. A. H. Dykes

IN his Presidential Address to the Association of Supervising Electricians on Wednesday of last week, Mr. A. H. Dykes devoted himself to an analysis of our present system of trade education as it affects what may be termed the rank and file of the nation. The matter was discussed at considerable length at the recent meeting of the British Association in Manchester, when a complete session of the Educational Section was devoted to the matter. Then, however, no specific industries were dealt with.

Mr. Dykes, on the other hand, made some definite suggestions with regard to the electrical industry, but before doing so indicated what is being done elsewhere in similar directions. The object behind all this discussion, of course, is to deal with boys either before leaving school or immediately afterwards, and to give them such training as will make them painstaking and industrious craftsmen. It is notorious, of course, that in Germany this problem has been tackled in a far more systematic manner than here, and Mr. Dykes gave complete details of the trade school in Munich which every boy between fourteen and eighteen working in any particular trade must attend. Similarly in this country the Gas Light & Coke Company has instituted a very successful scheme for training their employees in conjunction with the London County Council, the scheme being one combining practical training and general educational class work. As something on the same lines is now suggested for the electrical industry, it may perhaps be remarked that boys are indentured for a term of four years, commencing between the ages of 14 and 16. During the first six months they are engaged in a special workshop, where they learn the use of tools and receive brief lectures from the Company's foremen dealing with the practical part of their work. The next six months they go out in the district with the fitters. This routine is followed in

the second year, during the whole of which time nine or ten hours per week are spent during working hours at the Westminster Technical Institute, where the London County Council have arranged special continuation classes in mechanical drawing, shop arithmetic, &c. After the end of the second year the educational classes are held in the evening, and by a system of weekly, monthly, and terminal reports the Company is kept in close touch with what is going on.

A scheme somewhat on these lines has been worked out by Mr. R. W. Paul for training electrical instrument makers, and, following this up, Mr. Dykes urges employers in the London district to make a commencement by agreeing on a uniform system of apprenticeship. There should be no premium, or, at any rate, only a nominal one. The term should be at least for four years, terminable by the master at any time in the event of laziness, disobedience, or improper behaviour on the part of the apprentice. This, although it might seem unfair, he thinks is necessary to prevent a lad making himself a nuisance in the belief that he could not be discharged. One of the conditions of the indenture should be that the master must allow the necessary time during working hours for the boy to attend the trade school, at least eight hours per week being suggested, during the whole term of the apprenticeship or for not less than the first two years. Mr. Dykes added that he had no reason to believe there would be any difficulty in arranging with the Council and Board of Education a scheme of combined practical and theoretical education, the masters undertaking the practical work, including instruction by foremen and practical men, and the L.C.C. providing special continuation classes at, say, two convenient centres. Both employers and employees would be represented on the Board of Management.

A discussion followed the reading of Mr. Dykes's address, and it is probable that an attempt will be made to give practical effect to this suggestion. The idea seems to be to arrange for the Association of Supervising Electricians and the Electrical Contractors' Association to discuss the matter.

CATALOGUES, PAMPHLETS, &c., RECEIVED

HOLOPHANE INSTALLATIONS.—The illustrated handbook just issued by Holophane, Ltd. (12 Carteret Street, Queen Anne's Gate, Westminster, S.W.), is one of the best got-up booklets of its kind that we have seen for a long time. The object is to show that the Holophane system of illumination is capable of being adapted to any class of building or style of architecture, and there is no better method of doing this than by photographs of actual installations, especially when the photographs show such a degree of technical and artistic merit as in this case. There are separate sections relating to churches, public buildings, railways, private houses, banks and offices, industrial lighting, etc., and in addition to being highly instructive, it will certainly be found very useful for reference purposes by electrical contractors and architects.

ELECTRIC FIRES.—One of the most, and possibly the most, complete lists of electric fires, has reached us from Drake & Gorham, Ltd. (1 Felix Street, Westminster Bridge Road, S.E.). The pamphlet gives prices for, and describes, fires of the Bastian, Belling, Quead, Ferranti, Falco, and Jackson types, and together with the illustrations gives the contractor ample information.

METAL FILAMENT LAMPS.—Pamphlet No. 236 from Drake & Gorham, Ltd. (1 Felix Street, Westminster Bridge Road, S.E.) gives illustrations and prices of all types of metal filament lamps, including half-watt lamps and fittings. A useful feature is the photometric curves, showing light distribution with various forms of Holophane reflectors.

Enemy Shareholders.—At the Bow Street Police Court last week the Phoenix Telephone & Electric Works, Ltd., were ordered to pay fines and costs amounting to £185 10s. for failing to send to the Public Trustee particulars of shares or stocks in the Company held by or for the benefit of enemies. It was stated during the course of the proceedings that the Company had a capital of 8,284 £1 preference shares and 2,757 ordinary £s. shares, and of these, 1,284 preference and 426 ordinary shares were held by four persons residing in Germany. It was not suggested that there had been any deliberate desire to conceal the facts, inasmuch as the return of shareholders made by the Company to Somerset House showed the holding of all the shareholders, but this return, it was held, did not constitute compliance with the Trading with the Enemy Amendment Act.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

QUESTION No. 1,464.

A three-phase supply of about 50 kw., chiefly for power purposes (induction motors), is taken through a static transformer, the primary pressure being 2,000 volts, and the secondary 200 volts. Discuss how many ammeters and voltmeters are absolutely necessary and how many desirable.

(Replies must be received not later than first post, Thursday, October 21st.)

ANSWERS TO No. 1,462.

Please describe an inexpensive workshop method of varying the frequency of 60 periods 50 per cent. either up or down; expensive and elaborate arrangements out of question, as the changes are only required for testing purposes.—"W. E. L."

The first award (10s.) is given to "E. H." for the following reply:—

Undoubtedly the most satisfactory method would be to have an alternator driven by a commutator motor, but the expense would probably be prohibitive. The alternator could be driven by a slip-ring motor designed for the maximum speed, but the value of the resistances to give the necessary speed variation would be very large, especially if the minimum speed is required with a small load.

If "W. E. L." possesses two induction motors, of which one at least must be of slip-ring type, the following method may prove the most convenient.

Connect the 60-cycle supply to the stator windings of the slip-ring motor *A*, and the rotor terminals to the apparatus or machinery to be tested. If the rotor be held stationary, the frequency thus obtained is the same as that supplied to the stator, the motor then acting as a transformer. Next, couple the second motor *B* through a belt and pulley of suitable size to the first machine *A* so that the rotor of the latter is being rotated at a desired speed. Then if R_1 =synchronous speed of *A* in r.p.m., R_2 =speed at which its rotor is being driven by *B*, p =pairs of poles on *A*, and f =supply frequency, we have $f = \frac{R_1 p}{60}$.

Now if the rotor of *A* is being revolved in the opposite direction to that of the field, the relative speed between the rotor and the rotating field is $(R_1 + R_2)$ r.p.m., so that the frequency induced in the rotor is given by

$$f_1 = \frac{(R_1 + R_2)p}{60} = f + \frac{R_2 p}{60}.$$

On the other hand, if the direction of rotation of *A* is the same as that of the magnetic field, the speed at which the rotor cuts the latter is $R_1 - R_2$, and the corresponding frequency is

$$f_1 = \frac{(R_1 - R_2)p}{60} = f - \frac{R_2 p}{60}.$$

By varying the size of either or of both pulleys, any desired value of R_2 , and consequently of the frequency, can be obtained. If the value of the rotor voltage is unsuitable, a transformer can easily be inserted either in the stator or in the rotor circuits.

The second award (5s.) is made to "L. R." for the following reply, which we print in slightly abridged form:—

The simplest method of obtaining the frequency change mentioned is by means of a small induction motor with wound

rotor and means for driving the rotor when necessary. If the frequency in the stator is f_1 cycles per second, that in the rotor will be the same when the motor is standing still, but will be reduced when running in the proportion of the slip, so that

$$f_2 = f_1 \times \frac{n_1 - n_2}{n_1} = f_1 \times s.$$

If we regard the induction motor as a transformer, we shall see that it consists of a set of primary circuits, which are supplied from the mains, and of a set of secondary circuits. Electromotive forces will be set up in both windings; a back E.M.F. in the primary or stator winding; and in the secondary, or rotor winding, another E.M.F., namely, that which drives the rotor current. Let Z_1 be the number of stator conductors in series in any one phase of the stator, and Z_2 be the number of conductors in series in any one phase of the rotor, and let the flux (per pole) that is common to stator and rotor be denoted as N . Then we shall have for the two electromotive forces induced in the primary and secondary the following expressions:—

$$\left. \begin{aligned} E_1 &= kf_1 Z_1 N / 10^8 \\ E_2 &= kf_2 Z_2 N / 10^8 \end{aligned} \right\}$$

Here k is the Kapp coefficient of value about 2·14. Assuming that k is practically the same for both windings, we have

$$\frac{E_2}{E_1} = \frac{f_2 Z_2}{f_1 Z_1};$$

or, inserting the value of f_2 ,

$$\frac{E_2}{E_1} = \frac{n_1 - n_2}{n_1} \cdot \frac{Z_2}{Z_1} = s \frac{Z_2}{Z_1}.$$

As the slip is the ratio of secondary frequency to primary frequency, if the natural slip be altered in any way, for instance, by mechanically driving the rotor, the desired frequency is obtained at the rotor terminals, and the electro-motive force is substantially given by the above equation. (In practice other considerations arise to vary this, and for a full analysis of the matter reference should be made to "Alternating-current Phenomena," by Steinmetz, pp. 262 to 279.)

This kind of frequency-changer is commonly used for changing from about 25 periods up to about 60, the rotor being mechanically driven backwards against the torque. Mostly a synchronous motor is employed connected to the primary mains, which by over-excitation compensates also for the lagging current of the frequency converter.

Another machine has been provided by Brown, Boveri & Co., and comprises an alternating-current commutator generator self-excited, each field magnet pole having two windings excited by voltages displaced by 90° in phase. By regulating the current flowing through one of the field windings the voltage only is altered, and by regulating in the circuit of the second winding only the frequency is changed. This also is a simple machine with great control. It is fully described in Patent No. 7,061 of 1911.

The Electric Vehicle Committee.—A meeting of this Committee was held in London under the chairmanship of Mr. R. A. Chattock on October 1st. Mr. V. Mason took his seat on the Committee as the representative of the Tramways & Light Railways Association. The Committee had submitted for their inspection, by the Krieger Electric Carriage Syndicate, Ltd., the first of the new "Ward" light delivery vans to arrive in this country from America. As to further publicity work, it was decided that no more could be done at the present time than to concentrate upon keeping going successfully the official organ, *The Electric Vehicle*. The further standardisation of details in connection with lead plate batteries was discussed, and the Committee will now await the decision of the Accumulator Makers' Section of the B.E.A.M.A. upon their proposals.

The Institution.—The following are the arrangements for the first half of the forthcoming session:—November 11th, Presidential Address by C. P. Sparks; November 25th, "Difficulties of Design of High-speed Generators," by Prof. A. B. Field; December 9th, "The Design of High-pressure Distribution Systems," by J. R. Beard; January 13th, "The Predetermination of the Performance of Dynamo Electric Machines," by Prof. Miles Walker; January 27th, "The Possibilities in the Design of D.C. Traction Motors, &c.," by N. W. Storer.

The Council have elected Mr. J. E. Kingsbury to be Honorary Treasurer of the Institution in place of the late Mr. Robert Hammond.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 7th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

19,492/14. Electric Driving of Charging Pump of Internal-combustion Engine. A.E.G. The charging pump is driven by an electric motor started from a special source of power, such as an accumulator, but normally run from a dynamo driven by the engine. (Five figures.)

19,977/14. Train Lighting. C. H. VIDAL. A system in which the dynamo is excited by a current caused by the difference of pressure between the battery and the generator. The two halves of the battery are connected in series as regards the load circuit, and the generator is provided with two armatures and commutators in a common field. The armatures are connected across the respective halves of the battery, one being wound to give approximately the normal pressure of half the battery and somewhat higher pressure for charging one of the halves of the battery at a time. (One figure.)

24,766/14. Vapour Lamp. H. J. S. SAND. An improved "solid metal" vapour arc lamp using the vapour of a metal such as cadmium, in which the adherence of the metal to the glass on cooling is minimised by the presence in the lamp of a loose fine powder, such as zirconia. (Two figures.)

3,002/15. Signal Lamp. A. H. MIDGLEY and C. A. VANDERVELL. A light hand-signalling lamp for use on aircraft, with a handle like that of a revolver with the trigger arranged to work the shutter. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Heating and Cooking: COLLINS and COLLINS [Heating elements] 20,728/14; SMITH [Electric heating of steering wheels] 24,049/14.

Instruments and Meters: FAWSSETT [Induction instruments] 7,270/15.

Storage Batteries: JOEL [Accumulator charging] 23,189/14.

Switchgear, Fuses and Fittings: LUNDBERG, LUNDBERG, LUNDBERG and PEGG [Switches] 367/15; R. BOSCH [Band resistance for use with pedal switches] 11,480/15.

STEPNEY ELECTRICITY ACCOUNTS

THE annual report dealing with the Electrical Department of the Stepney Borough Council for the year to March 31st, 1915, is interesting first of all because of the large net profit, namely £10,702, and secondly because although many London and provincial electrical and gas undertakings have found it necessary to advance their charges for power and lighting, it has not been found necessary at Stepney to depart from the pre-war tariff. The satisfactory financial result is in a large measure due to the peculiarly industrial character of the borough attracting a considerable number of Government contracts, for which a large amount of electric power is required. The number of units generated and sold were respectively considerably more than double the corresponding figures of four years ago, the number of units sold being 18,757,007, an increase of 2½ millions over the previous twelve months. The power units, 7½ millions, were slightly over 1½ millions up. In addition to this, private bulk supplies account for slightly over four million units, an increase of nearly half a million units.

It was in the East End of London that linking up between the electrical undertakings was first taken seriously in hand, and it is satisfactory to note that the arrangements under the agreement with the Poplar Borough Council for reciprocal supplies still continues to be a great convenience. At the end of December bulk supply to the Shoreditch Borough

Telephony and Telegraphy: SHEPARD & McKECHNIE [Submarine signalling] 21,680/14.

Traction: Soc. ANON. DES ETAB. L. BLERIOT [Car lighting] 16,935 & 16,936/14.

Miscellaneous: MARSHALL [Relighting miners' lamps] 13,443/14; BLACK [Signalling in mines] 17,000/14; LOCHHEAD [Signalling in Mines] 19,388/14; BRUCK [Magnetic separators] 20,551/14; THORDARSOX [Coil winding machine] 21,881/14; TAYLOR [Transformation of energy by condensers] 22,674/14; Macdonald [Electric bells or gongs] 23,211/14; GARDNER [Vibratory contact makers] 24,475/14; HATTON [Electric clocks] 24,637/14; O'DONNELL (Hodges and Smith) [Electric alarm for mines] 1,119/15; MELLERSH-JACKSON (Posen) [Pocket flash lamps] 2,934/15; Wood [Conductors] 9,336/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Ignition: Soc. ANON DES ETAB. L. BLERIOT [Dynamo-magnetic ignition] 11,566/15.

Incandescent Lamps: MACKAY [Lamps] 12,994/15; ORANGE [Lamps] 12,995/15.

Opposition to Grant of Patents

Opposition has been entered to the grant of patents on the following specification:—

29,980/13. Metal Filaments: WOLFRAM LAMPEN A.-G. Alloys of tungsten and another metal with a small proportion of a third metal which acts as a catalyst to facilitate sintering.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS AND TRANSFORMERS: LANCASTER DYNAMO & MOTOR CO. and R. S. MCLEOD [Reversible boosters] 14,373/02; SIEMENS SCHUCKERTWERKE [Variable frequency alternator] 9,048/09.

Electrochemistry and Electrometallurgy: O. IMBAY (Soc. Anon. d'Etudes Electrochimique, Geneva) [Arc furnace for promoting gaseous reactions] 13,952/04; L. PATTHOFF [Electro-deposition of metals on steel] 14,058/04 and [Electro-galvanising] 14,059/04; LANGHEIN-PFANHAUSER WERKE A.G. [Electro-deposition] 14,091/09.

Heating and Cooking: A. F. BERRY [Heating by induced currents] 13,107/09.

Telephony and Telegraphy: W. P. THOMPSON (Ges für drahtlose Telegraphie) [Wireless circuit tester] 14,451/07.

Traction: H. LEITNER [Train-lighting dynamos] 12,645/05.

Council was inaugurated, and will be continued until September, 1916. During the past year the full supply contemplated when the agreement was entered into early in 1914 could not be given or taken in view of the unavoidable delay in the installation of machinery for both undertakings.

The total cost per unit sold was 1'024d. against 1'022d. per unit in the previous twelve months, and, in reviewing this, cognisance must be taken of the increased cost of coal and the abnormal conditions prevailing generally. At the same time the full effect of the high price of coal is not apparent in the accounts under review, and must more seriously affect the results for the current year. The undertaking has also suffered through the inability to obtain plant which was on order, which would have resulted in considerable economies in the cost of production.

Owing to the restrictions placed upon capital expenditure by the Treasury, the further hiring out of motors has been discontinued, and they are now being supplied under short-period hire-purchase terms. This policy has been adopted elsewhere irrespective of the ban on capital expenditure, and it has been found that electric motors can now be relied upon to such an extent that users prefer to purchase them in this way.

In dealing with the balance available, it has been decided to allocate £6,165 towards expenditure of a capital nature, to add £2,000 to reserve, and, after meeting various other smaller sums, to carry forward a balance of £1,134.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

In a lecture at the University College, London, on Wednesday last week on science during the war and after the war, Professor J. A. Fleming gave some interesting particulars with regard to the use of wireless telegraphy on aeroplanes and airships. The difficulties with aeroplanes, he explained, are considerable in consequence of the weight of the apparatus. A military aeroplane when loaded to its fullest extent has in addition to the pilot an observer, a certain quantity of bomb ammunition, and a gun equipment. Hence the necessity for the wireless apparatus to be as compact and light as possible. It is laid down as essential that the weight of the apparatus must be kept below 100lb., and equipments have been designed weighing only 30lb. The French use a 70lb. set. Another difficulty is the disposal of the aerial wire. Sometimes it is made of aluminium, and is stretched across the planes on insulators, but there are objections to that arrangement. Another way is to let the wire trail out behind the machine when in use, winding it up when not wanted. Many airmen, however, object to this method, owing to the risk of the wire catching in the propeller or trees. Messages can be sent from aeroplanes a distance of about 30 miles, and, for the most part, the receiving stations are the well-known Marconi portable pack sets. The noise of the engine and the rush of air, said Professor Fleming, renders the reception of messages very difficult, especially as they are sent in secret code, and every letter must be heard distinctly. Efforts, however, have been made to devise methods of reception which appeal to the eye instead of to the air, but the exceedingly small currents set up in the aerial wire by the received current has rendered the problem so difficult that it has not yet been completely solved. Another difficulty to be got over in wireless from aeroplanes is the efforts made by the enemy at jamming. With airships, Professor Fleming continued, there are other difficulties. Airships of the Zeppelin type are usually constructed with a framework of aluminium containing eighteen or twenty balloons inflated with hydrogen. The earth being at negative potential compared with points above it, the balloon takes the potential of the air where it happens to be, and there is great difficulty in avoiding sparks between the metal boxes in which the wireless apparatus is contained and the framework of the balloon. Sparks 1 in. long have been seen to pass in this way, and it is well known, said Prof. Fleming, that there is a strong possibility that Zeppelin Z4 was destroyed in this way through a spark given off when the ship was near the earth, the spark igniting the hydrogen. The Germans were perfectly well aware of these things, and, concluded the lecturer, there is room for much more experimental work in this connection. It could by no means be said that the practical problems of wireless telegraphy from airships and aeroplanes had been entirely solved.

ELECTRIC TRACTION NOTES

The only private Bill legislation left over for the autumn session of Parliament was the L.C.C. Tramways Bill. When this came before a Committee of the House of Lords last week, Mr. Vesey Knox, K.C., who led for the L.C.C., explained that there only now remained for consideration tramway proposals in Hackney and Bermondsey. The Home Office opposed the first scheme absolutely unless certain street widenings were carried out, which would cost £150,000—an obviously impossible suggestion at the present time, at any rate. The Bermondsey line is at present a horse tramway which it is proposed to convert to electric traction, and here again the Home Office suggested that the scheme should be suspended until arrangements had been made to secure a double track with a space of 9 ft. 6 in. between the edge of the pavement and the outside tramway rail. Evidence was given on behalf of the police authorities, who seem to gain in strength in their objection to tramways as years go by. Stress was laid upon the difficulty of regulating traffic at busy junctions owing to the tramways, but the Committee finally decided that the Bill should proceed.

We understand that considerable progress is being made

with the trolley omnibus scheme between North Ormesby, South Bank, and Normanby. The work is being carried out by a company which obtained Parliamentary powers a year or two ago, and would have been completed ere this but for the war.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Barking.—The Local Government Board has sanctioned loans amounting to £13,654 for the purpose of the electricity undertaking.

China.—In his report on the trade of Shanghai for 1914, Consul-General Sir Everard Fraser comments upon the importance of the market for electric lighting and power machinery in China, and points out that the business has been largely in the hands of German firms mainly because they were willing to undertake entire contracts and to finance them. Nevertheless, British installations have been completed in a number of important cities, and clearly it is a market which British engineers would do well to foster. The British Engineers' Association has already done good work in this connection.

Darlington.—One 3,000-kw. turbo-alternator, with surface condensing plant. Borough Electrical Engineer. Oct. 22nd.

Derby.—Application is to be made for a loan of £3,000 for mains and meters required for firms working on war contracts.

Rotherham.—The Engineer has reported upon the urgent need for further plant in the power station at an estimated cost of £20,000. As this is required to meet demands from firms engaged on war contracts, the Ministry of Munitions has been asked what assistance can be given in the event of the Corporation deciding to put down this extra plant.

Wigan.—A Local Government Board inquiry was held last week concerning a loan of £6,700 for electrical extensions. It was explained that to a large extent this expenditure is necessary by demands due to the war, and, owing to the small margin of plant now available, the supply to the trams had to be curtailed on one occasion when a mechanical stoker broke down. The urgency of the necessity for new plant was impressed upon the Inspector.

Wiring

Dublin.—Lighting of public baths and washhouses, Tara Street. Chairman, Public Health Committee. October 25th.

Dundee.—Lighting of Shipyard Y at the New Wharf, Gourlay's Old Shipbuilding Yard. J. H. Thompson, Engineer, Harbour Trust. Oct. 21st.

Gomersal.—Electric lighting of weaving shed for Gomersal Mills. Architect, C. D. Swale, 5 Cabinet Chambers, Leeds.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Altrincham.—School.

Darwen.—Extensions to Mossbridge Hospital.

Miscellaneous

Australia.—The Deputy Postmaster-General at Sydney requires 59 miles of paper-insulated lead-covered cable. Tenders by November 4th. This information, of course, is only of value to firms who can instruct agents by cable.

The Sydney Harbour Trust Commissioners require three electrically-operated railway freight-car transmitters. Tenders to the Commissioners, Circular Quay, Sydney, by January 31st. A copy of the specification can be inspected at 73 Basinghall Street, E.C.

The Deputy Postmaster-General, Melbourne, requires eleven sections of a lamp-signalling trunk-line switchboard for the Melbourne Trunk Exchange.

Cuba.—The Havana Electric Railway, Light & Power Co. has been authorised to construct a new double-track tramway.

London Lighting.—We commented in our last issue upon the new regulations regarding the lighting of private premises, shops, and railway trains in London. These, apparently, have been so effectively complied with that it has now been found that the reduced street lighting, which has been in force for some time, is insufficient to secure reasonable safety for the public in the streets. Consequently the Commissioner of Police, on the advice of the Anti-aircraft Department of the Admiralty, is considering to what extent public lighting shall be increased.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Edinburgh.—The Corporation has adopted a recommendation by the Electricity Committee to accept tenders for turbines and alternators for the new Portobello power station. Messrs. Fraser & Chalmers are the successful tenderers at £23,251, with Messrs. Vickers as sub-contractors for the alternators. The contract for condensing plant also goes to Messrs. Fraser & Chalmers at £7,611, with Messrs. Richardsons, Westgarth & Co. as sub-contractors. Delivery under above contracts is to be made in the summer of 1917. There was some opposition to the expenditure of so much money at the present time, but the recommendation was approved by 35 votes to 11, it being explained that the demand for current is extending at such a rate that the department would be in a very serious position if it did not look well ahead.

APPOINTMENTS AND PERSONAL NOTES

Mr. R. P. Wilson, A.B., Anti-Aircraft Corps, has been granted a temporary Sub-Lieutenancy in the Royal Naval Volunteer Reserve.

A Charge Engineer is wanted in the Bermondsey Electricity Department. (See an advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £87 10s. to £88 10s. (last week the same).

Competition with Germany and Austria-Hungary.—In connection with the campaign undertaken by the Board of Trade to assist British manufacturers and merchants to secure the trade formerly in the hands of German or Austro-Hungarian firms, the Board continues to receive a very large number of inquiries for the names of sellers or buyers of articles of which the sources of supply or markets have been interfered with by the war. Special arrangements have been made in the Commercial Intelligence Branch of the Board of Trade for dealing with these inquiries, and British firms interested as suppliers in any of the goods mentioned in the weekly list of articles (No. 41), which may be obtained on application, are asked to communicate with the Director of the Branch, 73 Basinghall Street, E.C.

Trade with China.—Mr. T. M. Ainscough, the Special Commissioner appointed by the Board of Trade to inquire into the conditions and prospects of British trade in China, has now returned to this country, and is prepared to interview (by appointment) representatives of British firms, who may be able to see him at the offices of the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

Agency.—The Board of Trade Journal states that an agent in Rome is prepared to buy or sell on commission electrical machinery of British manufacture.

Greenock Electrical Society.—This Society holds its first meeting of the new session to-morrow, Friday, when the Honorary President, Mr. Frank H. Whysall, Chief Electrical Engineer, Greenock, will give a lecture on "The Construction of Storage Batteries." Mr. W. B. Smith, Chief Assistant Electrical Engineer, Greenock, is the President.

LOCAL NOTES

Cheltenham: Electricity Department Progress.—There is general satisfaction with regard to the result of the working of the Electricity Department for the past year. There was an actual increase of £646 in revenue, and the very large increase in the output for power, namely, 55,000 units, is an indication that the 1d. per unit charge is a wise policy. The general figures for the past year are held as an indication that Cheltenham has resumed its normal condition in spite of the war.

Derby: Accident to Steam Turbine.—The Corporation have decided to take £800 from the reserve fund for repairs to a steam turbine at the Electricity Works. It was explained at the last meeting that the engineer-in-charge had been guilty of an error of judgment which had resulted in the destruction of a large part of the plant. The Committee were of the opinion that the engineer-in-charge was to blame, and they had requested him to resign.

Dover: Electricity Department Estimates.—The Electricity Committee, reporting upon the prospects for the current twelve months, anticipates a loss of £555, as against a net profit of £2,525 on the past completed year. This loss is accounted for in the greater cost of fuel and loss of the street lighting.

Keighley: Electricity Profits.—In his annual report the Borough Electrical Engineer points out that the year to March 31st, 1915, by reason of the engineers' strike and the war, had been one of the most trying possible for the Electricity Department. Generally speaking, the position remains the same as it was at the end of the previous twelve months, but there are signs of the development of a reasonably large night load. There was a net profit of £1,024 for the year compared with an estimated profit of £3,409.

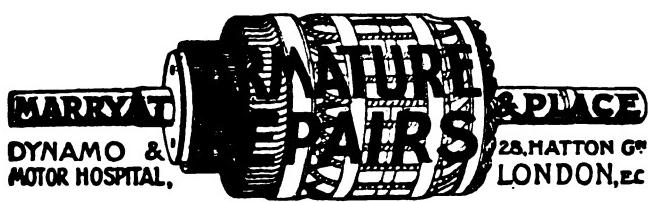

London: Marylebone: Increased Charges.—The Electricity Committee, in asking for a further increase of 10 per cent. to be made on consumers' accounts, points out that the increased price of coal, expenses incurred in guarding the Electricity Works, and allowances to employees on active service, alone amount to £9,787.

Apprenticeship Scheme.—The Electricity Committee has prepared a scheme by which a limited number of apprentices will be admitted to the department, and after a period of probation will be indentured. It is hoped by this scheme to minimise such troubles as were recently experienced in connection with the "running staff." Only youths over fifteen who have shown special qualifications or talent for engineering work, and who have received a good technical education, will be considered, and during apprenticeship every possible facility will be afforded. The remuneration will begin at 5s. per week for the first year, and gradually rise to 20s. per week, whilst all who show special diligence and ability will be given opportunities for filling vacancies on the permanent staff. This scheme is interesting in view of the presidential address by Mr. A. H. Dykes to the Association of Supervising Engineers, reported on page 418 of this issue.

London County Council: Greenwich Switchgear.—In October, 1913, the L.C.C. accepted the tender of the British Westinghouse Co., amounting to £17,915, for high-tension switchgear for Greenwich. Most of the work has been completed, but the Council is unable to accept delivery of the remainder until the second of the new turbo-generators has been erected. Under the terms of the contract the certificate for the work already done cannot be issued until the whole of the work has been completed, but the Highways Committee, in view of the circumstances, recommend that a further payment on account amounting to £4,885 should be made to the Company. This sum, together with the payments already made, represents 90 per cent. of the value of the completed work and 50 per cent. of the value of materials delivered.

Oldham: Electricity Staff Discontent.—A certain number of employees of the Oldham Electricity Department, who are members of the Municipal Employees' Association, recently made a claim for a war bonus of 2s. per week for their members earning over 30s. weekly. The demand was resisted, and notices to leave work have been sent in. At the moment these have not been acted upon, probably because the Town Clerk has informed the men that in his opinion they come under the operation of the Munitions Act. The men, on the other hand, deny this, and it is possible that the whole matter will go to Board of Trade arbitration.

Diesel Engine Users' Association.—The next meeting will be held on Wednesday, October 20th, at the Institution of Electrical Engineers, when the subject of lubrication of Diesel engines is to be further discussed.

SUMMARY

AN outline is given of the new British standardisation rules for electrical machinery shortly to be issued by the Engineering Standards Committee (p. 424).

A BRABANT paper has published a short description of the barricade of live electric wires erected by the Germans on the Belgian-Dutch frontier (p. 424).

WE give a description of new plant installed at the Limehouse generating station of the Stepney Borough Council, comprising two 5,000 kw. turbo-generators, with boilers, switchboards, and other auxiliary machinery. The new installation was officially inaugurated by the Mayor of the Borough last week (p. 425).

WE discuss one or two matters relating to increased electricity charges (p. 426).

OUR Questions and Answers columns deal with the calculation of starting and controlling resistances for a large induction motor (p. 427).

AMONG the subjects of specifications published at the Patent Office on Thursday last were compensation of motors for temperature, heating elements, and accumulator charging. A lapsed patent for metal filament mounting has been restored (p. 429).

THE difficulty in obtaining steel tyres is being considered by a Special Committee.—The liability of electric railways to damage by hostile aircraft has been discussed in Switzerland (p. 429).

A NEW catalogue of artistic electric light fittings is reviewed, and a description given of a new electric vehicle (p. 430).

A SHORT review of the October B.E.A.M.A. Journal appears on p. 431.

A 4,000-k.v.a. turbo-alternator, &c., is required at

Cape Town; generating plant at Chesterfield; two Diesel engines at Bo'ness; Diesel engine at Pembroke; and extensions are contemplated at Wolverhampton (£5,000) (p. 431).

THE Manchester Ratepayers' Association still continues its opposition to the Barton power station scheme.—Objection has been taken to the paying of the full salary to the Barnsley Borough Electrical Engineer, who has enlisted.—Rapid progress was made last year in the Barrow Electricity Department, the number of units increasing by no less than 72 per cent. (p. 432).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDANT.

Drills, 6.15 to 7.15; 7.15 to 8.15.

(To-day) Thurs., Oct. 21st: Section III., technical. Section II., shooting.

Fri., Oct. 22nd: Section IV., technical. Section I., squad.

Mon., Oct. 25th: Section I., technical. Section III., squad or working party.

Tues., Oct. 26th: Section II., technical. Section IV., shooting.

Thurs., Oct. 28th: Section III., technical. Section I., shooting.

Fri., Oct. 29th: Section IV., technical. Section II., squad or working party.

The Headquarters are at Marconi House, Strand, W.C. (Tel: City 682).

Sections for technical drill will fall in at the Headquarters of London Electrical Engineers (T.F.) at 46 Regency Street, S.W. Sections for squad, signalling, and working parties will fall in at the new Headquarters, Chester House, Eccleston Place, S.W.

All members who have not yet been measured for uniforms will attend at Headquarters on Friday, the 29th inst., for this purpose.

Fatal Electric Shock.—An inquest was held on Wednesday last week into the death of T. E. Green, who received a fatal electric shock in the South London Electric Supply Corporation's electricity works at Loughborough Junction. It appeared from the evidence that the deceased received a 3,000-volt shock whilst testing the insulators in one of the cells in the switchboard. No one was present at the time, but the unfortunate man was found leaning across the live conductors with his clothes on fire, his feet being on the top of a pair of steps. The evidence went to show that during a few moments' consciousness at the hospital the deceased stated that he had slipped. It was also stated that the regulation that all cells must be made "dead" before being interfered with was not complied with.

Institution of Electrical Engineers: Western Section.—The first meeting of the session will be held in the Bristol University on Monday next, October 25th, at 5.30 p.m., when Mr. D. E. Roberts, the chairman, will deliver his address.

Institution, Birmingham Section.—The 1915-16 session of the Birmingham Local Section of the Institution of Electrical Engineers opens on Wednesday next, October 27th, at the University, at 7 p.m., when Col. J. F. Lister, the Chairman, will deliver his address.

NEW BRITISH STANDARDISATION RULES FOR ELECTRICAL MACHINERY

In a Paper on the "International Standardisation of Electrical Machinery," read before the Institution of Electrical Engineers in December, 1913, Mr. A. R. Everest discussed the necessity for establishing standards for the design of electrical machinery, and indicated the work which had been done in this direction by the International Electrotechnical Commission. This body had studied the subject through its various National Committees; it had collected information and discussed the subject at its various meetings; and, finally, it had established the necessary data in such a form that it was available for practical purposes, with the result that various countries had taken up the task of remodelling their national standardisation rules in accordance with the standards developed by the I.E.C.

In this country the Engineering Standards Committee has been engaged upon this task, and is now arranging for the publication of new "British Standardisation Rules for Electrical Machines and Transformers." An outline of these rules is indicated by Mr. Everest in an article in the current issue of the *B.E.A.M.A. Journal*.

The most important feature of novelty appears to be the adoption of the "continuous maximum" basis for rating. The practice in this country has hitherto been to rate a machine at a certain load and to specify a daily permissible overload for a limited time. It is now proposed to abolish these overload allowances and to fix the rated load at that load which the machine will stand continuously without time limit and without exceeding the specified temperatures. In other words, the nominal full load of a particular machine will be 15 to 20 per cent. higher than it would be according to the old rules. Thus a machine which was called, say, a 100-h.p. motor capable of 25 per cent. overload for a certain time will in future be called a 115-h.p. or a 120-h.p. motor, according to the load it is capable of taking for an unlimited time, and no overload will be specified. This is at least a more rational procedure, and it will have the advantage of making a British machine directly comparable as regards rating with a foreign machine. Of course, a machine may be capable of overload; it may develop sufficient torque, or have sufficiently good commutation, and be mechanically strong enough, to take a large overload, and the necessity for this will be recognised; but the point is that overload can only be applied when the machine is below its ordinary "full load" temperature. When the machine reaches this temperature no overload is permissible, except, of course, momentarily.

A change in the nominal full load of a machine will naturally make changes in its nominal performance in other respects. For instance, consider an induction motor rated at 100 h.p. capable of developing a torque corresponding to 200 h.p. If its nominal full load is in future to be 120 h.p., its maximum torque will be 66 per cent. in excess of full load instead of 100 per cent. as before, though actually, of course, it has not changed. Similarly the new "full load efficiency" will not in general be the same as before, but will be the efficiency, in this particular case, at 120 h.p. instead of at 100 h.p. The point of maximum efficiency also may be changed; if it was formerly 90 per cent. of full load, it will in future be 75 per cent. in our chosen example.

For the special cases of continuous variable load with recurring high peaks there is provided a special "duty cycle rating," a machine for such duty being rated for test and comparison purposes at a value of continuous steady load which would produce the same temperature rise as the special load with known recurring peaks.

For intermittent service the "short-time" rating already familiar in the case of crane and hoist motors is retained. Traction motors are not covered under the forthcoming issue of the new Rules, being reserved for special treatment.

With regard to temperature rise, it has been the practice to allow a rise of 15° C. in association with the overload of about 25 per cent. The nominal full load is now increased to cover this 15°, but as there is to be no time limit, the increase in rating will be something less than 25 per cent.

The limits of temperature rise are specified for different insulating materials, and are dependent on two factors: the highest temperature which may be reached by the insulating materials, and that which may be reached by the cooling air.

The tables of permissible temperatures and temperature rises given in the new Rules are expressed in terms of "observable" temperatures, i.e., temperatures as measured by thermometer or by the method of resistance. An indica-

tion is given of the particular method which should be employed for measuring the temperature of each part of a machine.

The maximum temperature to which the cooling air may rise is fixed at about 40° C. as an average figure, which, however, may vary slightly under abnormal conditions of location, weather, &c. For high-voltage machines, lower temperatures rises are permitted on account of the greater internal temperature differences due to thicker insulation. Special provision has been made for the case of large turbo-alternators where methods of temperature exploration may be employed which would not be commercially feasible in smaller machines.

The high-pressure tests differ little from existing good practice.

After allowing for the differences introduced by the adoption of the old "overload" condition as approximately the new British "rated load," it will be seen that the values assigned as limits for temperature rise, high-pressure tests, and other features by the B.E.A.M.A. Committee differ very little from the values now assigned by the Engineering Standards Committee. It is rightly pointed out by Mr. Everest that this is the best possible testimonial to the thoroughness of the Association's preliminary work, and of the painstaking efforts of every member of the Committee to which that work was entrusted.

THE ELECTRICAL BARRICADE BETWEEN BELGIUM AND HOLLAND

THE Dagblad van Noord-Brabant publishes an interesting description of the high-tension "electrical barricade" which the Germans have erected between Belgium and Holland to prevent unauthorised crossing of the frontier by the unhappy people of the former country.

Seen at a distance, this resembles a hedge formed of wires and posts. One can see from far off notice-boards upon which the Germans have inscribed in three languages: "High-tension current: Risk of death." The barrier is formed of seven wires fixed on white insulators. The five middle wires, covering a height of about two metres, are attached to oak stakes driven into the ground, and on either side of these are thicker wires on oak poles—probably the feeders. The pressure employed is 2,000 volts. At each side of the conductors and about half a metre from them are a series of four protecting wires to protect people from coming against the charged wires by chance, so that contact with the live wires is only made if anyone tries to climb over.

Death from Electric Shock.—At the works of the Lancashire Ordnance Company, Heaton Norris, last week, a workman received a fatal electric shock in rather peculiar circumstances. A number of men were lifting an electric motor with chain blocks, when one of the chains came into contact with a cable running on an insulator close by. The cable was insulated, but at the point of contact with the insulator the insulation had come away, with the result that the man received an electric shock through the chain. The voltage was said, at the inquest, to be about 286 volts.

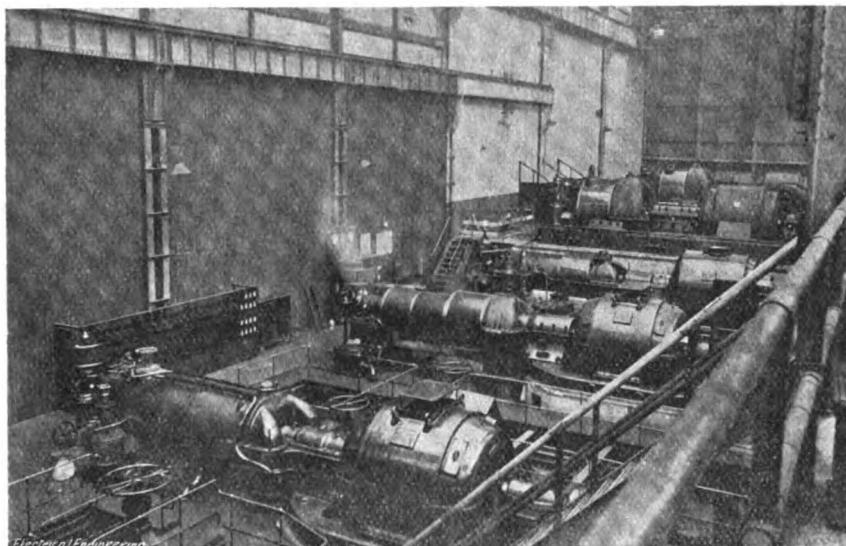

More Osram Strength.—The marvellous strength of Oram drawn-wire lamps has been demonstrated in the most practical manner many times, but there are few more striking examples of Osram strength than the one here recorded. During the Zeppelin raid in London on June 4th a house was so badly wrecked as to render its being pulled down and completely reconstructed. Two years ago the place was fitted with electric light, and a dozen 32-c.p. Osrams installed. All these lamps were found intact after the attack, although the opal shades were smashed to fragments.

Explosives.—In his Presidential Address to the Association of Engineers-in-Charge last week, Mr. Frank Bailey, joint managing director of the City of London Electric Lighting Co., chose explosives as his theme. He gave an interesting survey of the history of fulminates, propellents, and fillers, and referred to the unfortunate early history of guncotton, which at first a most unstable mixture, was subsequently made one of the safest of explosives.

Birmingham and District Electric Club.—Following the decision at the Annual Meeting last year, it has been decided to hold a dinner in honour of the new President, Mr. W. G. L. Riddle, on Saturday, Oct. 23rd, at the Swan Hotel, New Street.

EXTENSIONS AT STEPNEY ELECTRICITY WORKS

THE first section of the Limehouse generating station of the Stepney Borough Council was put into operation in the autumn of 1909, and since that date the demand for electricity has grown at such a rapid rate that considerable extensions have become necessary. As early as June, 1912, the Borough Electrical Engineer and Manager, Mr. W. C. P.

VIEW OF ENGINE ROOM.

Tapper, M.I.E.E., was instructed to report on the question. He presented a report advising the doubling of the station buildings and the immediate installation of two 5,000-kw. turbo-generators, together with the necessary boilers and auxiliary plant, at an estimated cost of £197,750. The report was adopted, and the work has been carried out and recently completed. The new plant was officially inaugurated on Thursday last, when the Mayor of Stepney, Mr. H. T. A. Chidgey, J.P., started up one of the new turbo-generators.

The very rapid growth of the power demand is shown by the following figures :—

| | |
|---|--------|
| H.p. of motors connected Sept. 30th, 1911 | 9,987 |
| " " " " " 1912 | 13,220 |
| " " " " " 1913 | 15,797 |
| " " " " " 1914 | 17,821 |
| " " " " " 1915 | 21,623 |

The extension to the buildings has been carried out upon the same lines as the original buildings, viz., in ferro-concrete. The contractors for the execution of the work were Messrs. Drew-Bear, Perks & Co., of Battersea, S.W.

The new boiler-house installation comprises four water-tube steam boilers by the Howden Boiler Co., Ltd. The specification calls for a normal evaporation of 33,000 lb. of water at 150° F. to steam at 200 lb. pressure per hour per boiler, with a heating surface of 6,700 sq. ft. and 190 sq. ft. grate area. Each boiler is in six elements, with upper and lower drums connected together with about 6,700 vertical tubes all 2 in. in diameter, and the necessary balancing water and steam pipes between the drums. Each element is provided with a safety valve, and there are two feeds to each boiler. Each boiler is fitted with internal superheaters, and is complete with all the necessary external platforms and ladders. The whole of the steam fittings are of Messrs. Hopkinson's make.

The stokers (two to each boiler) are of the Underfeed Stoker Co.'s moving-grate type, and are worked in conjunction with their hot-air economisers, forced draught, and Messrs. Prat's patent induced draught chimneys, with the object of obtaining as nearly as possible a balance draught at the stoker-grate level. These economisers, two to each boiler, are placed in the flue immediately

above the boiler and under the chimney. To each boiler there is an induced draught fan and motor and forced draught fan and motor, these being mounted above the level of the top of the boiler upon platforms close to the bases of the "Prat" chimney. At a convenient height above the boiler-house floor level each boiler is provided with a gauge board, upon which are mounted the following instruments :—The steam gauge, two superheat gauges, the forced draught motor ammeter, shunt regulator and draught gauge, the induced draught motor ammeter, shunt regulator and draught gauge, and the balanced draught gauge. This arrangement enables the stoker to have the working conditions of the boiler always under observation. The stoker drive is suspended on the under-side of the boiler-house floor and operates patent spring clutch gear to give motion to the grates.

The coal-handling plant extension consists of a double mono-rail telpher track running over the tops of the coal bunkers, and one track extends for twenty feet into the yard at the north end of the building.

A new telpher, of Messrs. Strachan & Henshaw make, has been added in order to cope with the increasing coal supplies, and to ensure continuous working in the event of a breakdown to either telpher machines.

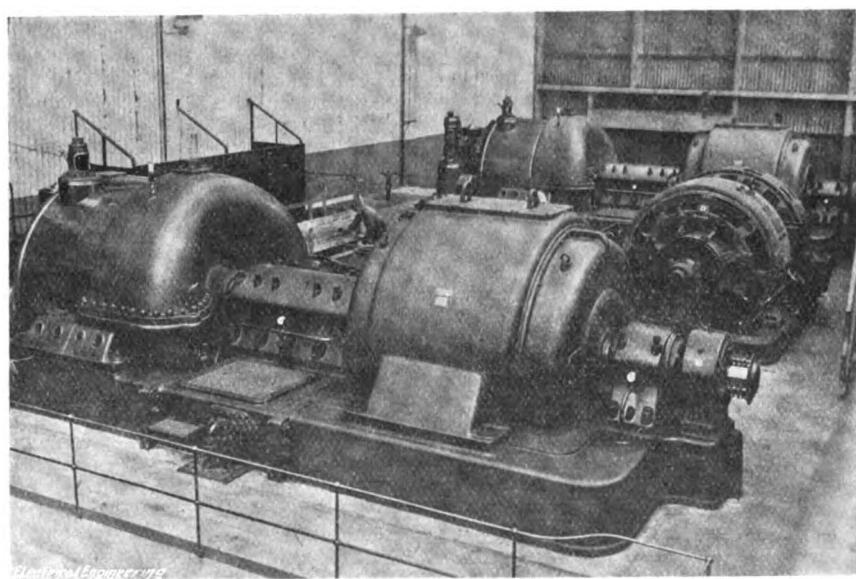

For handling the coal stock at the north end of the boiler-house a three-ton electrically-driven jib crane, manufactured by the Chatteris Engineering Works Co., of

Chatteris, Cambridge, has been erected, with a maximum working radius of 45 ft. A coal receiving and discharge hopper is provided in the yard at the end of the telpher track.

In the existing boiler feed-pump room has been installed a Weir steam turbine-driven feed pump, having a capacity of 10,000 gallons of water per hour against a pressure of 250 lb. per sq. in.

The exhaust steam from the turbine is turned direct into the hot well overhead through a kinetic heater.

The engine-room extension, of which a general view is given in our first illustration, consists of two 5,000-kw. Escher-Wyss turbines of the Zoelly impulse type, coupled to two Brown-Boveri three-phase alternators, 6,600 volts between phases at 50 periods. These sets are capable of generating 25 per cent. overload for two hours and 50 per cent. overload

NEW ESCHER-WYSS-BROWN-BOVERI TURBO-GENERATORS.

for half an hour, running at a speed of 1,500 revolutions per minute. The working steam pressure is 180 lb. at the stop valve at a temperature of 500° F. The contract figure for the full load steam consumption at unity power factor is

13.31 lb. per kw.-hour, subject to a tolerance margin of $\frac{1}{2}$ per cent.

An interesting feature of the installation is the attachment to the alternators of Heenan & Froude air filters, each capable of cooling and cleansing 25,000 cubic ft. of air per minute. These filters are of the rotary type, the lower half of the sheet cylinder being in water. The air comes in contact with water in the form of a thin film, and is delivered at the filter outlet in a natural condition after the dust and impurities of the air have been eliminated. The filters are placed in the basement, and the necessary water supply for them is led from the condensing plant.

Two surface condensers of Messrs. Escher, Wyss & Co.'s make are erected immediately below the turbines, each having 10,760 sq. ft. of cooling surface, with wrought-iron cylindrical shell, drawn brass tubes, tinned and rolled brass tube plates.

The pumping plant for each set, which is placed in the basement between the main turbine foundations, consists of one steam turbine-driven circulating water centrifugal pump, rotary air pump, condenser extraction pump, and hot well force pump, all mounted upon one bedplate and coupled in line to one shaft, running at a speed of 2,000 revolutions per minute.

It is so arranged that the steam from these auxiliary turbines can be either turned into a stage of the main turbine or into the hot well by means of a Holden & Brooke kinetic heater, thus in the latter case regaining the latent heat units of the steam.

The condensing arrangements are such that either condensing plant can be used with either turbine, or in case of emergency both turbines could be run on reduced loads upon one or other of the condensing plants. Furthermore, the exhausts from the main turbine have been so arranged that the turbine can exhaust to atmosphere in the event of a sudden failure of the condensing plant.

A 50-ton overhead electrically-driven crane has been erected by Messrs. Stothert & Pitt, of Bath. This crane is provided with a slow hoisting motion, capable of dealing with loads from 5 tons to 50 tons at a lifting speed of from 2 to 6 ft. per minute, and a quick motion for dealing with light loads up to 5 tons at the rate of 20 to 40 ft. lift per minute. There are three motors, each running at 700 revolutions per minute, one for lifting, one for travelling, and the third for hoisting.

Upon the new engine-room floor level, and between the two 5,000-kw. alternators, has been erected a Bruce Peebles 1,000-kw. motor-converter. This machine is similar to other machines of this firm's make, several of which have already been installed and in operation for some years in the generating station and sub-stations.

In order to secure greater safety in running of the motor-driven auxiliary plant, alternator field excitation, and pilot lighting of the station, a battery of 260 cells has been installed. The capacity of the battery is 500 ampere-hours for one hour, and it has been installed by the D.P. Battery Co., of Bakeswell. For charging this battery, a combined battery booster and feeder booster of Messrs. Siemens' make, together with the necessary switchgear, have been added to the plant. Under normal conditions the battery will be floating across the main D.C. bus-bars. Should the main bus-bar supply from any cause fail, or the pressure drop abnormally, the rush of current from the battery brings out a pair of three-way overload breakers, one in the positive side and one in the negative side of the system, instantaneously cutting the battery off the bus-bars and leaving it on the auxiliary power circuit. In addition, should the motor of the booster set be cut off from the supply, and allow the boosters to race upon a weak field, change-over switches are operated by a pair of relays coupled across the brushes of the motor, thereby cutting out the boosters.

Upon the new switchboard gallery, which immediately overlooks the turbo-alternator sets, have been placed six panels of Messrs. Reyrolle's new type extra-high-tension ironclad gear, and also the rheostat regulating gear for the alternator fields. The above gear includes two machine switches, two bulk-supply panels, and two coupling switches. Following upon the original lines there are duplicate three-phase bus-bars, the section of each bar being 1 sq. in. The switches are contained in boiler-plate tanks with cast-steel tops.

The whole of the circuits to and from the switchgear are protected with Merz-Price protection. In addition, the generator panels are provided with rotary type field switches with an electrical interlock between them and the main switch. This interlock prevents the field switch from being opened before the main switch, and provides for the automatic tripping of the field switch when the main switch operates, and ensures that the field switch is closed before the main switch. The fields of the exciter are separately excited at 240 volts from

the L.T. D.C. supply. These panels are also provided with all the necessary synchronising sockets, signal lamps for "switch on" and "switch off," power factor indicators, and open-dial type ammeters and wattmeters for each phase.

In addition to this switchgear, a Brown-Boveri automatic field regulator has been furnished for each alternator, and an electrical controlled governor switch for each turbine to regulate the speed direct from the gallery.

In order to cope with the increase of load and the bulk supply demands from Shoreditch and Bethnal Green, the following additional feeders, converter, and switchgear have been provided:—Two 1,500-kw. E.H.T. feeders laid from the Limehouse generating station to the Whitechapel sub-station; two 1,500-kw. E.H.T. feeders laid from the Whitechapel sub-station to Shoreditch; two 1,500-kw. E.H.T. feeders laid from the Whitechapel sub-station to Bethnal Green. All these feeders have been provided with pilot cables for Merz-Price protection gear. E.H.T. Reyrolle switchgear has been added to the respective sub-station switchboards to control these feeders.

ELECTRICITY CHARGES

THE general tendency on the part of electricity supply authorities to increase their charges owing to higher working costs raises a question of some interest concerning municipal electricity undertakings. As a general business proposition an increase in working costs must necessarily be reflected in the selling price of the article, and electricity supply is no exception to this. Certain factors, however, come into play when dealing with municipal trading which have the effect of putting these undertakings on a somewhat special footing.

Municipal supply station engineers as a body desire nothing more than that their undertakings should be run on orthodox business lines, but, of course, their environment to a large extent prevents this. In the larger undertakings the effect of this environment is less felt than in the smaller ones, as the profits made are sufficient to enable reasonable reserve funds to be built up, to pay away amounts to the relief of rates and frequently to retain a certain amount as working capital. It is noteworthy also that only a few of the larger and more important undertakings have increased their charges up to the present. Their financial stability is such that they can continue to sell at the old tariffs. With the smaller undertakings, however, the position is somewhat different, as it is usually impossible to provide for a reserve fund and at the same time to relieve the rates out of the profits. The rule has been rather to sacrifice the reserve fund in favour of rate relief, and the full effect of this offence against economic laws is now manifesting itself. In all parts of the country there are undertakings whose margins of reserve are so small—in some cases nil—due to the policy of allocating sums to relief of rates instead of keeping the money in the undertaking, that they are unable to meet even a portion of the present temporary extra cost of coal and labour. Surely that is the object of a reserve fund, and where undertakings have contributed to the relief of rates the consumer has just cause for complaint if the whole of the present increased cost of working is put upon him.

Another matter is that of public lighting supplied from municipal electricity works. The cost of this, of course, is a burden which is shared by the ratepayers as a whole. There are cases where compulsory reduction of the public lighting and its inevitable effect upon the electricity department revenue is one of the reasons put forward for increasing the charge to the ordinary consumer. Seeing, however, that the general body of ratepayers presumably benefit from the reduced cost of public lighting, should the loss in the revenue to the supply department be made up wholly by increasing the charge to the consumer of electricity for other purposes? One section of the ratepayers are thus being made to benefit another section in a matter in which both should share equally. The advantage the consumer gets by way of reduced rates—if any—due to less street lighting, he has to pay back to the electricity department in his higher bill. The question of rate relief is also mixed up in this, for it may well be argued that where this policy is adopted, electrical energy has not been sold at as low a charge as might be; in any case, the undertaking, and consequently the consumer, must suffer somewhere.

In view of the necessity of keeping the charges for electricity supply as low as possible in the times in which we now live, we think the points mentioned above are worthy of consideration by those municipalities who are affected by them.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,465.

A 20 h.p. D.C. motor has its armature lap wound with six conductors per coil, arranged in the slot in this order: 1, 2; 3, 4; 5, 6; i.e., two side-by-side and three deep per coil. In replacing a faulty coil the conductors may have been connected to the commutator so as to change their order numerically in the same slot thus: 2, 1; 6, 5; 4, 3. Would this change be detrimental to the running of the machine, enough to cause sparking?—"BOOSTER."

(Replies must be received not later than first post, Thursday, October 28th.)

ANSWERS TO No. 1,463.

How are the values of resistances for a controller for a 585 h.p., 485 r.p.m., 2,200-volt, 25-cycle, three-phase slip ring induction motor obtained? Rotor star connected, 700 volts, standing 360 amperes full load. The controller to have 12 stops. Is it standard practice to cut resistance first out of *B*, then *R*, then *Y* phase, and repeat until finally short-circuited, or to cut resistance out of all three phases together? If the former method is used, would it have an unbalancing effect on the rotor on any step, and tend to make it hunt, as one phase would be loaded more than the others? How would the resistance be calculated to give any particular speed on any particular step?—RESLETT.

The first award (10s.) is given to "Y. Z." for the following reply:

This question is really three in one, and the second should be answered first, as it explains the basis on which the information asked for in the first part is based. It is standard practice with some switchgear makers to cut resistance out of only one phase at a time as described in the question, as this method reduces the total number of contacts required in the starter, and only one set of contacts is required instead of three, so that the controller is simplified. The method is perfectly justifiable in many cases, although it undoubtedly does introduce unbalancing and possible bad starting under adverse conditions, since the total resistances in the three legs of the rotor will usually be unequal, resulting in an equilateral voltage being impressed on a triangle of resistance which is not equilateral. It is justifiable in the case of small motors particularly, as the starting period is in their case usually a short one, and irregularities during its course are not so important as in the case of a large motor, such as the question deals with. This is more essentially a case for maintaining an equal resistance always in each of the three legs of the rotor, as the third part of the question suggests that speed regulation may have to be done by means of the rotor starter, and in such a case it is obviously unwise to run any chance of unbalancing if the motor has actually to run at a reduced speed in actual working.

It is assumed, therefore, in what follows, that there will be three resistances all alike, one for each rotor leg, and that there will be 12 stops on each resistance, making 12 actual stopping positions between the "all in" and "all out" positions.

Come now to the first part of the question. The rotor

generates 700 volts between rings at standstill, which is 405 volts per phase. The total resistance per phase, including external and internal resistance, is given by dividing 405 by the rotor current per phase, which is permissible on the first step of the starter. If full load current were permissible then, the required total resistance per phase would be $405/360 = 1.125$ ohms.

As, however, it is unlikely that the supply would stand so large a demand all at once, it would probably be good practice to limit the demand on the first step to, say, one quarter of full load. Assuming that rotor current and load are proportional, which is true enough for the present purpose, this means a current per phase in the rotor of 90 amperes. Thus the required total resistance per phase is $405/90 = 4.5$ ohms. The resistance per phase of the rotor winding is not given, but it can be deduced. The speed is given as 485 at full load, which implies a slip of 3 per cent. The rotor generates 405 volts per phase at 100 per cent. slip, and hence at 3 per cent. slip it generates 12.15 volts. The current at full load is 360 amperes, and hence the resistance per phase is $12.15/360 = 0.03375$ ohms. The 3 per cent. given for slip is probably rather high, and the rotor resistance may, for the purpose of simplicity in calculation, be taken as .030 ohms per phase. Thus when the external resistance is "all out," the rotor circuit has .030 ohms per phase, and when the external resistance is "all in" the total is 4.500 ohms per phase.

Now it is as obvious as it is well known that a grading by means of a geometric series between the two extreme values of resistance gives the most even possible increments of current throughout starting. In this case, therefore, we have to start at .030 ohms, and in 12 steps arrive at 4.500 ohms by using a constant multiplier to pass from one step to another. Now $4.500/.030 = 150$, and the twelfth root of 150 is therefore the multiplier required. This root is 1.52, which means that the rise of current in passing from one step to another will be 52 per cent. always. The series is then as follows:—

| Step No. | Total Resistance in Circuit at this Step. | Resistance between Steps. | Amperes if Starting on full Torque. |
|----------|---|---------------------------|-------------------------------------|
| 0 | 0.30 | — | 550/360 |
| 1 | .046 | .016 | 550/360 |
| 2 | .069 | .023 | 550/360 |
| 3 | .105 | .036 | 550/360 |
| 4 | .160 | .055 | 550/360 |
| 5 | .243 | .083 | 550/360 |
| 6 | .367 | .124 | 550/360 |
| 7 | .559 | .192 | 550/360 |
| 8 | .850 | .291 | 475/360 |
| 9 | 1.290 | .440 | 313 |
| 10 | 1.960 | .670 | 206 |
| 11 | 2.970 | 1.010 | 136 |
| 12 | 4.500 | 1.530 | 90 |

4.470 = total resistance per phase in starter only.

On the assumption that the motor does not start until full current is reached, the current up till that point is simply 405 divided by the total resistance per leg as shown. After starting, the current settles to 360 each time if due time be allowed for accelerating, and rises momentarily to $1.52 \times 360 = 550$ on cutting out the next step. If the start be against less than full torque the motor begins to run earlier, and the current will rise always to 1.52 times the running value on cutting out a step, after motion has begun to take place. The above grading appears to be fairly suitable, allowing the motor to start on the fifth step, and allowing about two-thirds of the steps for the acceleration up to full speed. This is the worst possible case, too, unless the starting torque is in excess of full-load torque, in which case 12 steps is scarcely a sufficient number. It will be noted that the voltage between contacts never exceeds about 140 ($= 90 \times 1.52 = 136 \times 1.010$, &c.), and this should not be excessive for an oil-immersed switch, as this would presumably be.

If for any reason a considerably less voltage than 140 is desired, the number of steps must be increased suitably, but if only slightly less be considered desirable, then some resistance can be taken out of the steps near the starting end, and distributed amongst the steps near the running end; but this will of course increase the current increments at the latter end. On the whole, the true geometrical grading would seem to meet this case well.

The third column of the table gives the resistance to put in each step, and the fourth states the current that will have to be carried by that step on the assumption of full-load torque at starting. This furnishes complete particulars for designing the resistance. The form it takes will depend on whether it is

to be oil-immersed or not, whether wire or grids or some other material is to be used, and this can be left to be decided on the merits of each individual case. It should be noted that the resistance can be harder run near step 12 than near step 1, as the latter is in right up to the end; and the amount by which the wire can be overrun, if the controller is for starting only, will depend on the length of time starting is to occupy, whether the resistance be oil-immersed or not, and other conditions so impossible to assume without further knowledge that no very safe general rule can be given.

Turn now finally to the third part of the question, which indicates that the resistance may have to be used for speed regulation. In such a case, of course, it would have to be designed to carry its current continuously on as many steps as are to be used for that purpose, and the remarks above about the rating of the resistance for starting purposes would apply only to such portions as are used for starting only. For the calculation of the resistance for a particular speed less than the running speed it is necessary to know the torque which has to be exerted, as this determines the rotor current at which the necessary voltage is to be absorbed in the resistance. At any particular speed the rotor is generating a definite voltage, and the resistance must be such that this voltage will just allow enough rotor current to flow to balance the external torque. Thus suppose the rotor is to run at 80 per cent. of full speed, say 388 r.p.m. This is a slip of $500 - 388 = 112$ r.p.m. Now a slip of 500 r.p.m. generates 405 volts per phase, so a slip of 112 r.p.m. will generate $112/500$ of 405 = 90 volts per phase. At full-load current this means a total resistance per phase of $90/360 = .25$ ohms, or an external resistance of .22 ohms. For half of full-load torque, a total resistance of .50 ohms, and an external resistance of .47 ohms is necessary, and so on for any other case.

It must be noted that if any particular range of speed is required, the geometric grading on that part of the controller will very likely have to be departed from, and some compromise effected in regard to the value of successive steps. This may upset other points, such as current increment, or volts between steps, and it may become necessary under certain conditions to increase the number of steps should the controller have to fulfil the double function of starting and regulating under full-load torque conditions.

It is to be noted that, in the above treatment of the points raised in the question, some assumptions have been made which may not be strictly theoretically correct, such as that the rotor impedance can be added, arithmetically, as a resistance to the external resistance throughout. How far this disturbs the result can be seen for each case separately, but the approximations which have been introduced have the merit of leading to an extremely simple treatment, and have no bad effect on the starter or controller calculated as indicated. The method described does, in fact, give good results in practice, and that, after all, is the only condition which need to be fulfilled when the case is a purely practical one, as this is.

The second award (5s.) is made to "ALPHA" for the following reply:—

The total value of starting resistance will depend upon the amount of current rush permitted at the moment of switching on. Since this point is not mentioned in the inquiry, it will be assumed that there are no restrictions imposed by the supply company in this case, and that the usual practice of allowing full-load current to flow on the first step may be followed. Since full-load current in the line corresponds to full-load current in the rotor, and the rotor voltage per phase = $\frac{700}{\sqrt{3}}$ = 405 volts, the total resistance per phase will be $\frac{405}{360} = 1.125$ ohms.

The full-load speed of the motor is given as 485 r.p.m., corresponding to 3 per cent. slip, so that the resistance per phase of the rotor itself is $1.125 \times 0.03 = .034$ ohms. The external resistance will therefore be $1.125 - .034 = 1.091$ ohms per phase, or 3.273 ohms total. The resistance will be star connected, and on a motor of this size it is probable that the first stop of the controller will be arranged to connect the stator windings to the line with only two of the resistance legs joined, the second stop joining up the third leg in Y, and the fourth and succeeding steps short-circuiting portions of the starting resistance, in accordance with the usual practice. With a controller having 12 stops this means that the resistance will be divided into ten parts. The divisions must be so made that the ratio of the total resistance (including the rotor windings) on any one stop to that on the next stop is constant. The required ratio is found from:—

$$n \log A = \log (R+r) - \log r,$$

where n = number of portions into which the external resistance is divided,

R = total external resistance,

r = total resistance of rotor windings.

In the present case this gives $A = 1.42$.

The total resistance (external + rotor) in circuit on each stop

is found by dividing that on the preceding stop by this ratio, and the value of each division by subtracting successive steps as shown on the following tabulation:—

| Controller Stop. | Total Ohms. | Ohms Per Division. |
|------------------|----------------------------|--------------------|
| 1 | One leg open. | |
| 2 | 3.375 | Resistances in Y |
| 3 | 2.38 | .995 |
| 4 | 1.68 | .7 |
| 5 | 1.18 | .5 |
| 6 | .83 | .35 |
| 7 | .58 | .25 |
| 8 | .41 | .17 |
| 9 | .29 | .12 |
| 10 | .21 | .08 |
| 11 | .15 | .06 |
| 12 | .102 (rotor windings only) | .048 |

It is standard practice to cut out resistance from each phase in turn. This causes some slight unbalancing, but not sufficient to affect the operation of the motor in any way, except to slightly increase the heating.

The speed of an induction motor depends on the torque exerted as well as the resistance in the rotor circuit. In practice the slip (i.e., the difference between the synchronous speed and the running speed), may be taken as proportional to the total resistance in the rotor circuit, and to the torque exerted, bearing in mind that there is a certain "pull-out" torque (say about three times full-load torque) above which the motor will not carry the load, but will be "stalled," and that as this torque is approached the slip increases more rapidly than the load. The full-load speed of this motor is given as 485 r.p.m., and the synchronous speed will be 500 r.p.m. The slip with full load torque and a resistance (rotor windings only) of .102 ohms (.034 ohms per phase) is therefore 15 r.p.m. = 3 per cent. If the motor is required to run at, say, two-thirds speed with full-load torque, the slip will be 167 r.p.m. = 33 per cent., and the total resistance in the rotor circuit must be $102 \times \frac{33}{3} = 1.122$ ohms. The nearest stop to this would be No. 5 on the above tabulation, 1.18 ohms, which would give a speed of 326 r.p.m., the slip being $1.18 \times \frac{174}{500} = 174$ r.p.m. This would presumably be near enough to the required speed, especially as the speed would change with every variation in the load—thus at half full-load torque the slip would only be approximately $\frac{174}{2} = 87$ r.p.m., giving a speed of $500 - 87 = 413$ r.p.m. It is evident from this that it is impossible to keep an induction motor running at a steady reduced speed by resistance in the rotor circuit, unless the load can be held dead constant.

If the resistances are for continuous speed regulation they must of course be designed to carry the full-load rotor current continuously. If for infrequent starting service only, a common rule is to allow full-load current for half a minute on the first stop, and one minute on the last, the intermediate resistances being graded between these limits. This is, of course, governed by the length of time which the motor takes to run up to speed, and the frequency with which it must be started.

The insulation between the grids and the frame of the resistance should be designed for the full rotor voltage (700 volts).

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 14th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

20,728/14. Heating Elements. G. H. AND H. F. COLLINS. A heating element comprising a former of straight formation and of curved cross section, having transverse ribs upon its outer surface following the curve, and forming parallel recesses and a coiled resistance wire laid backwards and forwards in the recesses so that a large portion of the curve is in contact with the material of the former which is caused to glow. (Four figures.)

23,189/14. Accumulator Charging. H. F. JOEL. An accumulator charging contact apparatus which when the cell is placed in position for charging automatically cuts out of circuit a resistance equivalent to the cell, and when the cell is withdrawn restores the resistance to the circuit. (Thirteen figures.)

7,270/15. Meter Compensation. E. FAWSETT. A temperature compensating device for induction type meters, consisting of correcting bands or shading coils round the poles having a negative temperature coefficient of resistance. (One figure.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: SMITH and OWEN [Conduit joints] 20,254/14; WILLIAMS, WARWICK and ANCHOR CABLE Co. [Junction boxes, &c.]

Ignition: DAIMLER-MOTOREN-GES. [Sparkling-plug] 9,783/15.

Instruments and Meters: LANDIS & GYR S.A. [Prepayment meters] 20,458/14; WESSEL [Hot-wire current limiters] 4,987/15.

Switchgear, Fuses, and Fittings: SCHMIDT [Switches for simultaneously operating electric light and camera shutters] 20,295/14; TRIER [Automatic regulators] 23,368/14.

ELECTRIC TRACTION NOTES

An interesting point was raised last month during the debate on a vote for extending the electrification of the Gothard Railway to the Erstfeld-Bellinzona section. Although at the moment there is no war between Germany and Switzerland, it was suggested that the question of liability to aerial attack might be considered. It was argued that aircraft could easily destroy the large power-houses such as those at Göschenen, Wassen, or Amsteg, and so paralyse a large portion of the Swiss railways, and that perhaps, in the circumstances, the policy of extending the electrification to further lines might be reviewed with this possible contingency in view. It is doubtful, however, whether the argument is a sound one. From recent events in this country it is clear that aircraft, flying at great heights to render it less liable to destruction, has necessarily a very poor aim. With the mountain protection of Switzerland even greater heights might be necessary if the aircraft enjoyed immunity from destruction, and it is therefore more than probable that the power-houses would not be so good a target as the lines themselves.

A meeting of the Metropolitan Association of Electric Tramway Managers was held on Friday, the 15th inst., at the Municipal and County Club, Whitehall Court, S.W., when the following were present:—Messrs. Ullmann (East Ham), Chairman; Schofield (Leyton), Vice-Chairman; Moffet (West Ham), Mackinnon (London United), Hammond (Metropolitan Electric), Mason (South Metropolitan), and Goodyer (Croydon), Hon. Secretary. Messrs. Ullmann and Schofield were re-elected Chairman and Vice-Chairman respectively, and Goodyer re-elected Hon. Secretary.

In view of the difficulty experienced in obtaining supplies

Telephony and Telegraphy: OLSSON and PLEIJEL [Telephone reflectors] 22,937/14.

Traction: SOC. ANON DES ETAB. L. BLERIOT [Car lighting] 16,080/14.

Miscellaneous: KNIFE and READ [Electric welding] 20,176/14; SCHIESSLER [Relays] 20,238/14; CLARK [Roentgen-ray bullet localiser] 20,595/14; ROBERTSON, BOWMAN, and RINGROSE [Colliery signalling] 21,637/14; JONES [Arc soldering] 21,822/14; CURTIS and IGRANIC ELECTRIC Co. [Electromagnetic valves] 21,824/14.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Miscellaneous: BRITISH WESTINGHOUSE Co. [Control systems] 12,340/15; QUARTZLAMPEN GES. [Treatment of liquids by radiation from quartz lamps] 13,624/14.

Restoration of Lapsed Patent

17,817/07. Filament Mounting. A. C. HYDE. An order has been made for the restoration of this Patent, which had been allowed to lapse. The specification describes a method of attaching metal filaments to leading-in wires by applying a metallic paste, and subsequently heating locally by an electric arc in hydrogen.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS, and TRANSFORMERS: B.T.-H. CO. (G.E. CO., U.S.A.) [Motor control] 13,380/05; M. LATOUR [A.C. motors] 14,697/06; A. G. BROWN, BOVERI ET CIE. [D.C. rotary transformers] 13,092/08; J. C. B. INGLEBY [A.C. armatures] 13,719/08.

Instruments and Meters: SCHOTT & GEN [Electrolytic meters] 14,288/09.

Switchgear, Fuses, and Fittings: W. FAIRWEATHER (Benjamin Elect. Mfg. Co., U.S.A.) [Cluster lamp-holders] 13,425/05; J. G. STATTER [Switches] 14,577/06; B.T.-H. CO. (G.E. CO., U.S.A.) [Motor-starters] 15,262/07; R. C. LYNESS [Switches] 15,151/09.

Telephony and Telegraphy: KØBENHAVNS TELEFON-AKTIESELSKAB [Automatic telephones] 14,851/06; F. RITCHIE [Telautograph current regulator] 13,957/08.

Traction: H. LEVNER [Train lighting] 15,325/09.

of steel tyres and other materials at the present time, to which reference was made at the annual meeting of the Tramways & Light Railways Association (ELECTRICAL ENGINEERING, September 30th, p. 398), the Council has appointed a Special Committee to deal with the matter, consisting of Mr. Harry England (Vice-Chairman), Mr. Fred Bland, and Mr. J. B. Tippetts. Members are invited to communicate with the Secretary and give particulars of the difficulties they are encountering.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The Western Electric Co., Ltd., have sent us a copy of the Western Electric News "Extra" in connection with the recent successful experiments in wireless telephony in America. The Western Electric News is a magazine published by their American firm. The long-distance wireless telephony experiment has already been briefly referred to in this column. Mr. Vail, President of the American Telephone & Telegraph Co., spoke by wireless from Arlington, Virginia, to Mare Island, Navy Yard, San Francisco, to Mr. J. J. Carty, the Company's Chief Engineer, over a distance of 2,500 miles on September 29th, and speech was clear. Certain sentences were spoken, and Mr. Carty repeated them back accurately over the trans-continental wire lines which were formally opened last January. The test was the combination of many months of experiments and tests. The officials of the Army and Navy communicated by wireless in the same manner with success, representatives of the Army Signal Corps and the Technical and Operating Departments of the Navy Department being present.

"ELECTRICAL ENGINEERING" TRADE SECTION

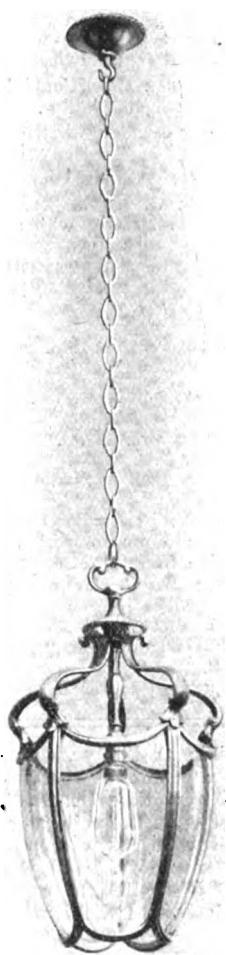

"EDISWAN" ELECTRIC LIGHT FITTINGS

A NEW catalogue of artistic electric light fittings has been issued by the Edison & Swan United Electric Light Co., Ltd. The Company announces that in consequence of a largely increased turnover for fancy fittings, they have decided to keep a larger assortment of stock designs. The new list is accordingly considerably enlarged, comprising nearly 200 pages with 500 handsome illustrations on art paper. At the back of the book is enclosed a quantity of introduction slips

of travelling 35 to 45 miles on a single charge, the average speed being about 10 miles an hour.

The battery, which is compactly mounted under the driver's seat, consists of 42 cells of the Philadelphia Storage Battery Co.'s traction type, with a total capacity of about 105 ampere-hours. It is fitted with an Anderson charging plug for charging in position, but it is so mounted as to be easily removable in three sections if it is desired to do the charging separately.

The motor is a 3-h.p. Westinghouse motor, four-pole, and runs normally at 80 volts, 600 r.p.m. It is placed in the

EDISWAN ELECTROLIER.

CEILING FITTING.

ARTISTIC BRACKET.

(with counterfoils) for contractors' use—a very good idea. A wide range of fittings is described, including pendants suitable for bedrooms and billiard-rooms, various styles of brackets, ceiling fittings, electroliers in "Sheraton," "Flemish," and "Georgian" styles, hall lanterns, &c. The shades for indirect and semi-indirect lighting are interesting in view of the development of high candle-power incandescent lamps.

The catalogue is a very artistic production, and will no doubt be much appreciated by users of fancy fittings. Any of the fittings illustrated can be seen at either of the Company's showrooms at 123 Queen Victoria Street and 71 Victoria Street.

"WARD SPECIAL" ELECTRIC VEHICLE

WE have had the opportunity of inspecting a well-constructed and compact form of electric delivery van by the Ward Motor Vehicle Co., of New York, who are introducing it into this country through the Krieger Electric Carriage Syndicate, Ltd., (48A Gillingham Street, S.W.). The car is built to carry a normal load of 750 lb., and is capable

centre of the chassis, and drives through a propeller shaft to the rear axle. It is series wound and controlled so as to start with the four field coils in series, and to run normally with the coils in two parallel groups. Starting resistances of the grid type are provided, and there are four speeds ahead and two reverse. The resistances and controller are placed under the footboard.

Although light in appearance, the car appears to be of robust design and construction, and will probably prove a successful competitor in its particular field.

THE B.E.A.M.A. JOURNAL

THE October number of the quarterly journal of the British Electrical and Allied Manufacturers' Association contains little in the way of official announcements or direct references to the activities of the Association itself. It includes, however, several articles of intrinsic interest. The most important of these, dealing with the new British standardisation rules for electrical machinery, is quoted at some length on page 424 of this issue. Other signed articles are "The

Organisation of Electrical Publicity," by A. G. Whyte; two polemical articles on the I.M.E.A. Bill, from opposite points of view, by H. Faraday Proctor and "A Member of the E.C.A.;" "Home Buying after the War," by Thomas Roles, written in response to an invitation which might very well have been refused; and a technical article on the control of A.C. motors by Frank Walker. There are several good editorial articles, fewer trade notices than formerly, and the usual number of manufacturers' advertisements. Except for the latter, in fact, the contents of the Journal appeal this time rather to members of the Association themselves than to their prospective customers abroad, to whom the first issues of the Journal were primarily dedicated.

ADVERTISING WINDOW SIGNS

THE illustration is of a window sign designed and made by Simplex Conduits, Limited, for the new showroom of the Glasgow Corporation Electricity Department, the opening of which was a public function in Glasgow last week. During the present trying times for shopkeepers, when the lighting restric-

tions in large towns are strictly enforced, it is useful to remember that windows lighted in this way are well illuminated, without flooding the street with light, or half blinding the observer.

It is curious that it should have taken a European war to impress correct window lighting—as many other things—upon us, but now it has been done there should be good business in such signs.

CATALOGUES, PAMPHLETS, &c., RECEIVED

EDISWAN RADIATOR LAMPS.—A leaflet from the Edison & Swan United Electric Light Co., Ltd. (Ponder's End, Middlesex), deals briefly with radiator lamps. Attention is drawn opportunely to the special flange cap which assures rigidity.

EDISWAN LAMPHOLDERS.—The Edison & Swan United Electric Light Co., Ltd. (Ponder's End, Middlesex), has sent us a card giving information regarding Ediswan lampholders.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Bo'ness.—The National Electric Construction Co. is to instal temporarily two 100-k.w. Diesel oil engines. These, together with the other necessary extensions of switchgear, buildings, &c., are estimated to cost between £6,000 and £7,000.

Cape Town.—One 4,000-k.v.a. steam turbo-alternator with condensing plant (or a unit of smaller or larger capacity provided that better delivery date is offered), and a 1,000-k.w. condensing plant. Consulting Engineer, H. D. Wilkinson, 4 Queen Street Place, E.C.

Chesterfield.—The L.G.B. has sanctioned a loan of £5,000 for new generating plant.

Pembroke.—A new Diesel engine and generator is to be installed at an estimated cost of £2,000.

Rathmines.—The Electricity Department requires a motor-generator. Borough Electrical Engineer. October 28th.

Wolverhampton.—A loan of £5,000 is to be applied for in connection with mains to supply firms engaged on Government work.

Wiring

Lanark.—Electric lighting of Hairmyres Colony. Consulting Engineer, W. Arnot, 163 Hope Street, Glasgow. November 1st.

London: L.C.C.—Thornfield Elementary School, Hammersmith, 240 lighting points. November 3rd. (See an advertisement on another page.)

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Blackburn.—Cinematograph theatre, Darwen Street.

Bradford.—Smallpox hospital (£16,000). The sanction of the L.G.B. has been obtained.

Miscellaneous

Glasgow.—The Parish Council and District Board of Control requires a twelve months' supply of electric lamps and fittings for their hospitals, asylums, &c. Clerk, 266 George Street. October 25th.

Ireland.—Twelve months' supply of electrical fittings, lamps, cable, wire, and arc lamp carbons for Great Northern Railway Co. Secretary, Amiens Street, Dublin. November 4th.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Berehaven.—The report and tender of Mr. P. H. Nugent, Electrical Engineer to the Rural District Council, upon the proposed electric lighting scheme, estimates that the capital cost will be about £1,500, and the annual cost about £75, not including maintenance of staff and plant. Mr. Nugent has undertaken to erect all the plant, &c., required, and the Council has accepted the offer.

Gillingham.—The Corporation has received a letter from the Anglo-American Oil Co., stating that the price of fuel oil for their Diesel engines was £5 2s. 6d. ex-Purfleet, or £5 13s. 9d. delivered at the electricity works. The Company intimated its willingness to fix up a contract for six or twelve months at these prices. The Board of Trade is to be asked for advice on the matter.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. Geo. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £87 10s. to £88 10s. (last week the same).

Liquidations.—A meeting of the British Drawn Wire Lamp Co. will be held at 59 Chancery Lane, W.C., on November 13th, at 11 a.m., to hear the Liquidator's account of the winding-up.

A meeting of creditors of Venner's Electrical Cooking and Heating Appliances, Ltd., will be held at Blomfield House, London Wall, E.C., on Tuesday, October 26th, at 12.30, to ascertain the wishes of the creditors as to the appointment of a joint liquidator.

Agencies.—A French dealer in accessories of all kinds for electric lighting, says the *Board of Trade Journal*, has considerable difficulty in meeting orders owing to shortage of local supplies, and desires to communicate with United Kingdom manufacturers.—An agent in Lyons wishes to represent United Kingdom manufacturers of electrical apparatus. Further particulars at 73 Basinghall Street, E.C.

APPOINTMENTS AND PERSONAL NOTES

The many friends of Mr. A. V. Gifkins, the well-known electrical engineer, of 68 Victoria Street, Westminster, and Bankipore, India, and late of Elstow Works, Bedford, will, we are sure, regret to hear that he was very severely injured

in the recent air raid. He is now in hospital in London, and is making slow but satisfactory progress. Needless to say, he will welcome any letters from old friends. They can be addressed to him at the office.

The late Second-Lieut. H. G. Byng, of the General Electric Co., who, it will be remembered, was killed whilst fighting in France on May 18th, has left estate valued £73,716.

Pte. F. H. Gooch, one of the leading members of Messrs. Drake & Gorham's wholesale staff, has, we regret to learn, just been killed in the trenches at Vermeilles, France. He joined the Cameron Highlanders on the outbreak of war, and was home on five days' leave in July.

An Assistant Manager is required for a telephone exchange in the East. (See an advertisement on another page.)

The Holmfirth Electricity Committee requires a Working Electrical Engineer at a salary of 45s. per week.

LOCAL NOTES

Ayr: *Electricity Profits.*—There was a net surplus of £1,248 for the year to March 31st, 1915, which has been placed to reserve fund, which now amounts to £5,351. The number of units sold was 82,822 less than in the previous twelve months, and the coal bill shows a decrease of £513 due to the use of very low grade fuel made possible by improved stoking apparatus installed last year.

Barnsley: *The Borough Electrical Engineer.*—At the last meeting of the Council a question was raised as to the salary (£450 per annum) of Lieut. A. E. Barker, the Borough Electrical Engineer. Alderman Wray observed that Mr. Barker could not serve two masters, and should not receive two salaries. An inquiry into the matter was promised.

Barrow-in-Furness: *Rapid Progress.*—Mr. H. R. Burnett, the Borough Electrical Engineer, in his report for the year to March 31st, 1915, stated that although large extensions of the plant and mains were only completed in 1914, the conclusion of an agreement in October last year with Messrs. Vickers for a supply to their naval construction works made it necessary to proceed at once with further large extensions to both plant and mains. These latter extensions comprise a 2,000-kw. B.T.-H. turbo-alternator with condensing plant, switchgear, &c., and a water-tube boiler capable of evaporating 30,000 lb. of water per hour supplied by the Stirling Boiler Co., together with economiser, &c. These extensions have cost £13,000 for plant and £8,000 for mains. With regard to the Hiring-Out Department, this has done useful work, but the effect would be greater if there was a showroom in a suitable position in the centre of the town. The total number of units sold for the year were 8,597,410, compared with 2,081,317 in the previous twelve months, an increase of 72 per cent. The net profit after meeting capital charges was £3,163, against £513 in 1913-14. The phenomenally large increase in output during the past year is again assured for the present twelve months, and this has precluded the necessity for an increase in charges.

Greenock: *Lecture on Accumulators.*—Mr. F. H. Whysall, the Borough Electrical Engineer, opened the session of the Greenock Electrical Society with a lecture on storage batteries. The lecturer emphasised the conclusions arrived at in his recent Paper to the Institution of Electrical Engineers, viz., that the use of storage batteries is a matter of increasing importance, and detailed their construction, at the same time calling attention to the latest improvements.

Heywood: *Bulk Supply.*—The work in connection with the provision of a bulk supply to the Corporation by the Bury Corporation is almost completed.

Hounslow: *Increased Charges.*—The Chairman of the Electricity Committee is in favour of increasing the charges for electricity by 10 per cent., but the Committee as a whole will not agree to this policy. He anticipated in consequence that there will in all probability be a deficit of £700 on the current year's working.

Kettering: *New Plant.*—A new generating set, supplied by the Brush Co., with Messrs. Siemens Bros. as contractors for the alternator, was started up last week. The cost of these extensions has been about £8,600.

Leigh (Lancs.): Proposed Showroom.—Dissatisfaction was expressed at the last meeting of the Corporation with a recommendation from the Electricity Committee that it is not desirable for the present to open any electrical showroom owing to the advanced prices of fittings. Councillor Dobb, Chairman of the Electricity Committee, however, explained that with the cost of fittings at its highest, it was scarcely

the time to embark on business of that sort. Nevertheless, the Council referred the matter back, several speakers expressing the opinion that it would be advantageous.

Manchester: *The Barton Scheme Still Opposed.*—The Manchester Ratepayers' Association has not yet abandoned its attempt to secure the postponement of the construction of the Barton power station. A letter has now been addressed to the President of the L.G.B., in which it is stated that the Corporation's affairs are managed under what is called a "system of government by committees nominated for the political parties." It is asserted that the Council itself has given practically no time to a consideration of the merits of the scheme.

Ross: *Increase of Maximum Charge.*—We referred on September 30th to the application of the Newquay Electric Light & Power Co. to the Board of Trade for an increase in the maximum charge in the Company's Provisional Order from 6d. to 8d. per unit. The Ross Electric Light & Power Co. has been successful in obtaining a similar increase, the Board of Trade having recently given its decision in favour of the Company.

West Bromwich: *New Plant.*—In order to enable the Electricity Department to meet the increasing demands from firms engaged on Government work, it has been decided to purchase a second-hand turbo-alternator set from Messrs. R. H. Longbotham & Co., of Wakefield. The cost is to be taken from the depreciation and reserve fund.

SUMMARY

SOME interesting observations with regard to electrical trade with China were made, in an interview with our representative, by Mr. T. M. Ainscough, the Special Commissioner appointed by the Board of Trade to inquire into the conditions and prospects of British trade in that country (p. 434).

THE report of the Bradford City Electrical Engineer for the past year shows a very satisfactory state of affairs, the net profit being a record. The effect of the Treasury ban upon capital expenditure is shown, but a considerable number of extensions which were in hand early last year are being completed (p. 434).

SUCCESSFUL experiments with the use of 5,000 volts direct current for traction purposes are described (p. 435).

WE give particulars with regard to the arrangements for next session of some of the Institution Local Sections (p. 435).

STANDARDS for "flex" with galvanised iron instead of copper wires, and insulation of reclaimed rubber, have been issued officially in Germany (p. 435).

THE under-feed stokers put in for the extension at the Stepney electricity works, which was the subject of an article in our last issue, are more fully described (p. 436).

OUR Questions and Answers page this week deals with the ammeter and voltmeter equipment for a small factory installation for lighting and power (p. 437).

WE give an account of some recent successful experiments in long-distance wireless telephony (p. 437).

Two patent specifications relating to telephone relays were published last week. Subjects of others include

electric welding and ceiling roses. A patent for a cab-signalling system is opposed (p. 438).

AN interesting discussion on the lubrication of Diesel engines is reported (p. 438).

EXTENSIONS estimated to cost £30,000 are contemplated at Coventry; new plant is required at Rawtenstall; and mains at Plymouth, Poplar, and Salford.—Stores are required by the Dublin United Tramways Co. (p. 439).

THE Maidstone Corporation has been fortunate in being able to sell to the Government, for wireless telegraph purposes, three small generating sets which have been replaced by a Ljungstrom turbine.—There was a net profit of £10,397 at Greenock last year after providing £2,442 for depreciation.—Figures are given of the progress of the Liverpool electrical undertaking (p. 440).

AN interim dividend at the rate of 10 per cent. per annum is declared by Callender's Cable & Construction Co.—Dick, Kerr & Co. also had a good year in 1914-15, but no dividend is recommended.—Messrs. Ferranti similarly do not declare an ordinary dividend (p. 440).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDANT.

Drills, 6.15 to 7.15; 7.15 to 8.15.

(To-day) Thurs., Oct. 28th: Section III., technical. Section I., shooting.

Fri., Oct. 29th: Section IV., technical. Section II., squad or working party.

Mon., Nov. 1st: Section I., technical. Section IV., squad or working party.

Tues., Nov. 2nd: Section II., technical. Section III., shooting, or working party.

Thurs., Nov. 4th: Section III., technical. Section II., shooting, or working party.

Fri., Nov. 5th: Section IV., technical. Section I., squad or working party.

Sat., Nov. 6th: Company Parade, 2.30 p.m.

Sections for technical drill will fall in at the Headquarters of London Electrical Engineers (T.F.), 46 Regency Street, S.W.

Sections for squad, signalling, shooting, and working parties will fall in at the new Headquarters, Chester House, Eccleston Place, S.W.

All members who have not yet been measured for uniforms will attend at Headquarters on Friday, Nov. 5th, for this purpose.

All men who draw haversacks and water-bottles for week-ends working parties are requested to return them to Headquarters on the following Monday.

Members desiring to have their own haversacks and water-bottles can purchase them at Gamage's, price 2s. 6d. haversack, and 5s. 9d. water-bottle.

The following Corporals have been appointed: C. McArthur Butler, Section II.; H. J. Golding, Section III.; B. C. Garman, Section IV.; R. T. Morris, Section IV.; T. Spiers, Section III.; H. Jantzen, Section II.; E. A. Ullmann, Section I.; J. M. Smith (Temporary Corporal).

For "Arrangements for the Week" see p. 439.

ELECTRICAL TRADE WITH CHINA

Interview with the Special Commissioner

MR. T. M. AINSCOUGH, the Special Commissioner appointed by the Board of Trade to inquire into the conditions and prospects of British trade in China, has recently returned to London, and has been good enough to grant our representative an interview. There is, he told us, an enormous market all over that country for electric light and power plants and apparatus, telephones, &c. Up to the present this trade has principally been in the hands of the big German and American firms, but the prospects of increasing trade are so good that it should be well worth the while of British electrical firms either individually or in groups to give greater attention to the Celestial Empire. At present British electrical firms have got very little further than the treaty ports, and there should be plenty of work to be done and orders to be obtained from the interior.

The present course of events is somewhat as follows:—A small town, say, decides to have electric lighting, and about a dozen native tradesmen and officials form a company. They will then apply to the nearest foreign firm for assistance in carrying out the scheme. The German firms have branches in most of the treaty ports, and, what is of equal if not greater importance, correspondents in all parts of the country. Immediately they hear of such a proposal they will send a Chinese-speaking and trained engineer from the nearest treaty port, and he will be prepared, if necessary, to spend a year or more seeing the right people and entertaining them. If he finds that there is competition, as will probably be the case if the distance from the treaty port is not great, his firm will, on his advice, be content to take the profit chiefly out of the subsequent sale of accessories, &c., making an agreement that the business in these shall go to the firm putting in the plant. In such cases long credit is not necessary, and an arrangement would probably be made, say, for one-third of the payment to be made with order, and another third on the arrival of the plant.

Mr. Ainscough is strongly of opinion that the future lies with active penetration into the country. If the firms desiring the trade cannot themselves establish their own branches, a great deal may still be done through merchants already established in China, but it is useless to attempt this in a haphazard manner. A thoroughly organised system must be introduced, and their own engineers must be on the spot to assist and work with the merchants in question. Although a knowledge of Chinese is not essential in the treaty ports themselves, it is indispensable for penetration into the interior, as well as a knowledge of Chinese character and business methods and customs. Mr. Ainscough suggests that engineers before going out should learn Chinese here; this is possible either in London or Manchester, and, of course, at Oxford and Cambridge. After, say, twelve months—or even six months—of lessons here and an equal time of concentrated application to learning in China, an intelligent man should be able to manage fairly well in the language.

As regards general sale of accessories, &c., apart from large light and power schemes, &c., price is the governing factor, as the buyers there know little of quality; this is practically the same everywhere where German competition has to be met abroad.

To conclude, however, the main thing is proper organisation. It takes time to establish, and the commercial men of engineering firms who are less busy than their colleagues who are more closely concerned with manufacture might well start at once.

THE BRADFORD ELECTRICITY DEPARTMENT

A VERY interesting report has been issued by Mr. T. Roles, the Bradford City Electrical Engineer, upon the working of the Electricity Department for the past year. Considering the abnormal conditions, the results achieved cannot be regarded as other than satisfactory. Although the output has not grown to anything like the same extent as in a number of previous years, an increase of nearly three-quarters of a million units is recorded, the total number sold being 28,743,718. Only the tramways supply has shown a slight falling off. When considering these results it is worthy to note that up to the end of November, 1914, the number of units sold for all purposes was lower than in the corresponding period of 1913.

Special attention is drawn to the success attending the supply to domestic consumers who have adopted the rateable value

system of charging, the units taken by such consumers representing an increase of practically 30 per cent. on the figure for the preceding twelve months. Mr. Roles' paper on this subject in conjunction with Mr. A. S. Blackman, Borough Electrical Engineer at Sunderland, at the I.M.E.A. meeting this year, will still be fresh in our readers' memories. Of the total of 1,333 domestic consumers 807 are charged on the rateable value system, as compared with 633 in the previous year, and the average units used per consumer by this class is 988, against 970 in the previous year.

The net profit for the year is £18,956, and a factor which has contributed to this is the decision of the Finance and General Purposes Committee to adopt the principle of accumulating sinking funds in connection with various corporation undertakings. The effect of this decision has been to reduce the percentage which the sinking fund contribution for the year bears to the capital of the Department to a figure more comparable with those obtaining with the majority of the municipal electricity supply undertakings in the country. A sum of £5,000 has been allocated to relief of rates, £6,910 has been expended on capital works, £114 applied to the depreciation of meters purchased from stock, and the balance of £9,437 has been transferred to the depreciation and renewals account.

Discussing the extension of the plant, Mr. Roles relates how during the early months of the war municipalities were urged to put in hand at once all extension schemes possible with a view to providing employment, whilst early this year, it having been found there was, if anything, a lack of labour rather than employment, and also for other well-known reasons, the Treasury decided to limit as much as possible the borrowings of local municipalities. For this reason the provisional sanction which had been given early in 1914 for a loan of £91,250 to extend the Valley Road works was reduced to £79,683, and an application in October last for £52,000 for mains, transformer chambers, &c., was finally reduced to £14,000. In July this year, the L.G.B. was asked to sanction a loan of £20,000 in connection with war work, but even here sanction was only given to the cost of the mains, &c., regarding which definite information could be given. Since then special application is made in respect of every case as it arises.

Considerable delays have naturally been experienced in completing the extensions at the Valley Road works, and it was extremely fortunate that the contracts were placed and well in hand before the Government found it necessary to exercise a complete control over the outputs of engineering establishments in the country, otherwise it is doubtful whether much of the plant would have been ready in time to assist in coping with this winter's load. The induced draught plant was completed and put into operation in October, the second cooling tower was put into commission in May, and the storage battery, regulating boosters, and switchgear were placed in regular service on July 5th. By the aid of this apparatus the boilers and generating sets can now be operated more economically by being kept loaded up to much nearer their full rated capacities for longer periods during the day than formerly, and a much more uniform steam pressure can be maintained, thus allowing sudden demands to be made with safety and certainty. The work in connection with the installation of the 5,000-kw. turbo-alternator is so far completed that preliminary trials have been made, and it is hoped that the various small details remaining to be finished will be dealt with in time to allow of the set being officially started up during the next few days. Similar remarks apply to the two 1,500-kw. rotary converters.

As a result of experiments made during the year, it has been found possible to run the sub-stations in parallel with the Valley Road power house on the D.C. as well as the A.C. side, and the plant is now regularly operated in this manner. Greater economy in running is thus obtained, due to improvement in the load factors of the generating sets, immediate additions to the converting plant in the sub-stations have been rendered unnecessary, and the supply to the various tramway routes dealt with from these sub-stations has been considerably improved.

After a reference to the successful work of the Publicity Department, whose activities at the moment, however, have been considerably curtailed owing to the holding up of further loans, Mr. Roles deals with the future prospects of the undertaking. Although the new connections obtained during the past twelve months will undoubtedly lead to the output of the present financial year being considerably in excess of the figure recorded in any previous year, it is not expected that the financial result will compare so favourably as the one now announced, owing to the higher works costs due to advances in the prices of coal and materials, wages, and allowances to dependents of employees serving with the Forces. Heavier capital charges will also have to be borne, on account of the new plant and mains, and to some extent owing to the high rate of interest which has now to be paid on loans. The rates will also be higher, not only on account of the increase in the amount, but also by reason of the assessment having been advanced. At the same time considerable economies should be effected by the new plant and, taken generally, the Committee are able to look forward with confidence to the future of the Department.

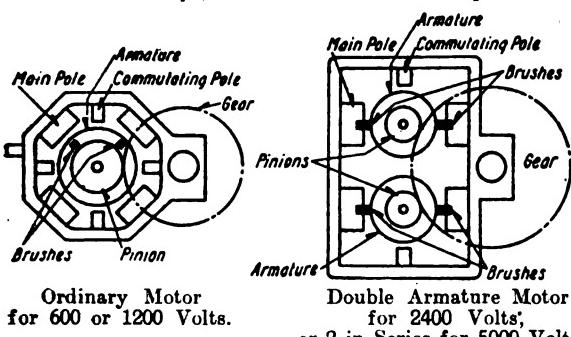

5,000 VOLT DIRECT CURRENT FOR TRACTION

THE use of very high pressure direct current for traction purposes has in the past been considered impracticable for many obvious reasons. That the difficulties are now, however, gradually being solved is shown by the fact that an installation of this type has recently been put into successful operation in Michigan, U.S.A. The equipment has been designed and manufactured by the Westinghouse Electric & Manufacturing Co., of Pittsburg, and is considered to be of an experimental nature, although it has been in commercial operation for about three months, and has so far proved entirely successful.

The features of the new system, which is described in the *Electric Railway Journal*, are briefly as follows:—

The power, which is supplied to the car at 5,000 volts through overhead wires, is obtained from three mercury-arc rectifiers, which receive power from a 60-cycle, three-phase system and are operated in series. Each car is provided with four 2,400-volt motors connected two in series, each motor having two bi-polar armatures in series driving the same gear wheel. A remarkable feature of the system is that the armatures can be arranged in parallel groups, so that the car will run on a 600-volt supply system in the vicinity of the town, and it can be changed over to operate at 5,000 volts on long-distance tracks.

The greatest difficulty to be overcome in providing an equipment of this kind is, of course, the design of the motors for such high voltages when space is so limited. In order to secure the maximum benefits from electrification, a railway must be able to run not only locomotives, but multiple-unit car service. Consequently, any system of electrification that hopes for recognition for heavy traction purposes must be suitable for operation on passenger cars. It is not so difficult in the case of electric locomotives to secure space for the necessary number of commutator bars and for the requisite creepage surface for insulation purposes, but it has been a serious problem to secure these requisites for a

5,000-VOLT D.C. EQUIPMENT—COMPARISON OF STANDARD MOTOR AND 5,000-VOLT MOTOR.

motor of the size required for ordinary passenger cars without exceeding the commercial limits in weight, cost, and dimensions.

The illustration which we have reproduced shows the manner in which the difficulties in the design of the motor have been overcome. A motor of this type, it may be said, is now on exhibition at the Panama-Pacific Exposition. It is known as the twin-armature bi-polar type, and it has many advantageous features for high-voltage work. A two-pole design permits the use of double the voltage on a given commutator that is possible with a four-pole motor, on account of the greater distance between the brushes. The twin armatures make the weight but little more than that of a corresponding four-pole motor. Fewer field coils are required than are used with the four-pole motor, and the two armatures, being geared to the same axle, act as one unit, and cut the pressure on the gear-teeth in half. The two armatures are connected in series, and consequently the voltage on each is reduced to lower limits. The form of the motor lends itself readily to a very effective type of insulation, and the mechanical construction is simple and strong.

The commutation is said to be sparkless, and there is absolute freedom from flashing over. Large creepage surfaces are supplied, both on armatures and brush-holders, in order to give immunity from earths. One characteristic that is incidentally favourable to the design is the fact that the current is small, being only 30 amps. for each 100-h.p. motor, and therefore only a few small brushes are required. Thus with the excellent commutation there is very little wear either on brushes or commutators—a very fortunate circumstance, as this means that the amount of carbon and copper

dust originating in the motor, and consequent risk of insulation failure, is small. It is fully recognised that upon the permanence of the insulation depends the success or failure of the motor, and this is something that time alone can determine.

Next to the motors, the control is perhaps the most important feature of the equipment, since the switches must close and open the high-voltage circuits properly, and must be insulated to stand continuously the maximum voltage to earth. In order to secure a relatively large number of breaks in series, each switch is made with two breaks in series. In construction the switches are very similar to the standard Westinghouse electro-pneumatic type. The starting resistances are of the ordinary grid pattern, with, of course, special insulation.

The auxiliary equipment for providing current for control and lights, and the air-compressor motor are operated at 150 volts supplied from a storage battery. This battery is placed in the main motor circuit between the motors and the rail. The auxiliary motors take less than 3 per cent. of the total power taken by the car.

The tests, which are being made on a line of twelve miles in length on the Michigan United Traction Co.'s system, have not yet continued long enough to enable one to draw conclusions as to the ultimate success of the use of 5,000-volt direct current for traction purposes. All that can be stated at the present time is that the tests have so far proved extremely satisfactory, and the fact that so many difficulties have already been overcome gives ground for hope that the system will be a commercial possibility of the future.

THE INSTITUTION LOCAL SECTION ARRANGEMENTS

THE Local Sections of the Institution of Electrical Engineers are proceeding very much on ordinary lines with regard to their meetings during the forthcoming session.

As we have already announced the opening meeting of the Birmingham Section was held on Wednesday last, when Col. J. F. Lister, the Chairman, delivered his Inaugural Address. So far Papers have been arranged for the next two meetings, viz., Nov. 24th, when Prof. A. B. Field will deal with "Difficulties of Design of High-Speed Generators"; whilst on Dec. 15th the Paper will be by Mr. J. D. Morgan, the Hon. Secretary, on "Notes on the Ignition of Explosive Gas Mixtures by Electric Sparks."

The programme of the meetings of the Yorkshire Section for the first half-year of the session is as follows:—Nov. 10th, Chairman's Address and Smoking Concert. On Dec. 8th Prof. A. B. Field will give his Paper on "Difficulties of Design of High-Speed Generators," and on Jan. 12th, 1916, Mr. J. R. Beard will deal with "The Design of High Pressure Distribution Systems."

The provisional programme for the Scottish Section has also been prepared. On Dec. 9th Mr. D. A. Starr, the Chairman, will give his Inaugural Address in Glasgow; the meeting on Dec. 14th will be in Edinburgh, when Mr. G. Wilkinson will read a Paper on "Electric Heating: Its Present Position and Future Development"; on Jan. 11th, in Glasgow, Prof. Magnus Maclean and Mr. D. J. M'Kellar will give part two of their Paper, "Distribution and Rise of Temperature in Field Coils." Meetings have been arranged for Feb. 8th in Edinburgh, March 14th in Glasgow, for which Papers will be announced in due course, and on April 11th the annual general meeting will be held in Glasgow.

The Chairman of the Newcastle Section, Mr. P. V. Hunter, will give his inaugural address on Monday, November 8th.

GERMANY USES IRON WIRE FOR "FLEX"

THE scarcity and high price of copper in Germany has reached such a point that "flex" is now to be made with iron wire instead of copper. In an official communication by the Verband Deutscher Elektrotechniker, published in the *Elektrotechnische Zeitschrift* of September 30th, standards are laid down for this material, it being mentioned in passing that zinc wire is unsuitable for it.

The wires are to be of galvanised iron, and two standard sections, 2·5 and 4 sq. mm., are fixed, equivalent to solid wires of about 15 and 18 S.W.G. respectively. The individual wires must not exceed 0·3 mm. diameter (about 31 S.W.G.). Vulcanised rubber 1 mm. radial thickness is employed for the insulation, and this may be made of reclaimed rubber. Samples have, however, to withstand a pressure test of 2,000 volts A.C. after 24 hours' immersion in water.

Standards for iron workshop flex have also been issued, with sections up to 16 sq. mm.

THE UNDERFEED STOKERS AT STEPNEY ELECTRICITY WORKS

WE referred last week to the extensions at the Limehouse electricity works of the Stepney Borough Council, involving an increase of 10,000 kw. in the capacity of the station. The underfeed stokers and the Prat "in-circuit" draught system are among the distinctive features, and we

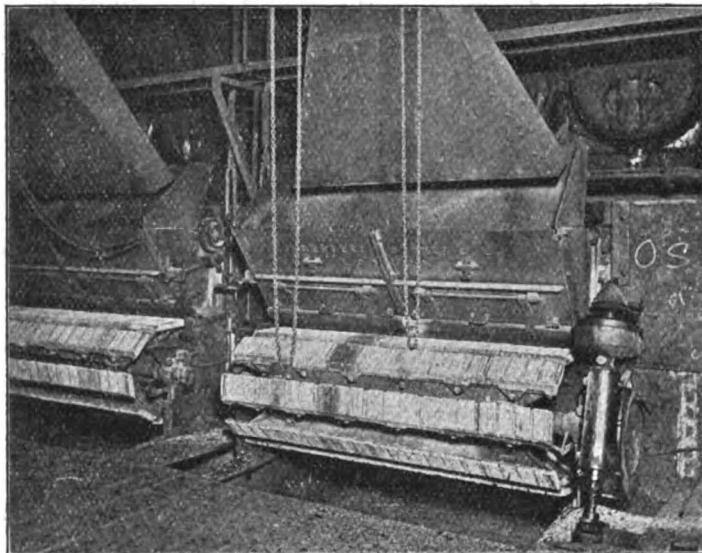

FIG. 1.—FRONT OF ONE OF THE FURNACES.

are able to supplement our description with some further particulars of these.

There are four Howden boilers, each having a heating surface of 6,700 sq. ft., designed to evaporate, normally, 36,000 and maximum 45,000 lb. of water per hour at a steam pressure of 200 lb. per sq. in., with a superheat of 200° F. Each of the four boilers is fitted with a pair of Underfeed travelling grate stokers, the width of each grate being 7 ft. 4 in., and the effective length 13 ft. 1½ in., giving a grate area per boiler of 192 sq. ft. The coal burnt normally per boiler upon each pair of stokers is 5,600 lb., and for the maximum overload duty 7,000 lb. The above evaporation are obtained with slack coal having a heating value, as fired, of 10,000 B.Th.U.'s.

The stokers are driven by shafting and reduction gear, which reduces the speed from 900 r.p.m. on the motor spindle to 70 r.p.m. on the stoker shaft. Each boiler is fitted with an "Usco" air heater having 54 elements and a heating surface of 3,132 sq. ft. The heaters are capable of raising the air 150° F. when the gases passing through the heater are at a temperature of 600° F.

Balanced draught is employed, the forced draught supplying the air to the grate under pressure, and the gases being drawn from the furnace by the Prat "in-circuit" system, capable of setting up at the base of the chimney ¼ in. w.g. at normal rating, and ½ in. for maximum rating. A Prat chimney, 79 ft. high from the crown to the floor-level and of 5 ft. 7 in. diameter, is mounted upon each air heater. The fan requires 10 h.p. under normal conditions, and 14·5 h.p. overload, and runs at a normal speed of 525 r.p.m. and a maximum speed of 675 r.p.m. Each induced-draught fan is driven by a direct-connected motor. The power absorbed by both forced and induced draught fan for each boiler at normal load is 28 b.h.p.

The forced draught for each boiler is obtained from a double inlet steel plate fan capable of delivering 28,160 cu. ft. of air per minute at a pressure of 2½ in. w.g. The fan runs normally at a speed of 590 r.p.m., and it can be varied by means of speed regulation on the driving motor from 525 to 650 r.p.m. The h.p. absorbed by the fan when supplying air to one boiler at normal rating is 18 h.p., but the forced-draught fan and motor plant are designed so as to provide air for two boilers if necessary.

The ashes from the furnaces are dumped at the back and removed from the basement below the boiler-house floor. In this basement is situated the main air trunk from which the

air is taken to the wind-boxes of each stoker, and also the driving shaft by means of which these stokers are driven.

The forced and induced draught equipment is all installed above the boilers. The gases leave at the front of each boiler, and are conveyed through uptakes to the heater chambers and thence through the heaters to the base of the Prat chimney. The platform immediately above the boiler, and approximately on a level with the heater chambers, carries the forced-draught fan and motor, and a second platform erected above this carries the induced-draught fan and motor. Both motors are mounted on common base-plates with the bearings of the fans which they drive. The forced-draught fan forces the air through the connecting trunk to the inlet of the heater, the outlet of which is connected by means of the vertical trunking with the duct in front of the stokers.

The motors are of the pipe-ventilated type.

With the exception of the air duct and driving shaft, each boiler constitutes a separate unit.

For those of our readers who are not intimate with the system of the Underfeed stoker, we add the following brief description:—The stoker consists of an endless moving grate of box-shaped fire-bars mounted upon chains, the links of which are rotated by sprocket wheels. The tops of the fire-bars are slotted for the delivery of air into the fuel. This air enters through rectangular boxes D (Fig. 2) at the side of the stoker, and flows into longitudinal chambers E. The upper surfaces of the latter are sloping at an angle of about 30 deg., and provided with longitudinal openings A running the whole length of the grate, which deliver the air into the open ends of the fire-bars. The supply of air is controlled by the adjustment of hinged dampers A, which are triangular in shape. The fuel is delivered into a feeding hopper (seen in Fig. 1) in the ordinary manner, and the quantity fed upon the grate is regulated by a sliding shutter worked by a rack and pinion motion; two doors (also seen in Fig. 1) enable the condition of the grate to be observed, and also permit of hand-firing if necessary.

The whole arrangement is well-designed, and it seems probable that extremely interesting figures as to the per-

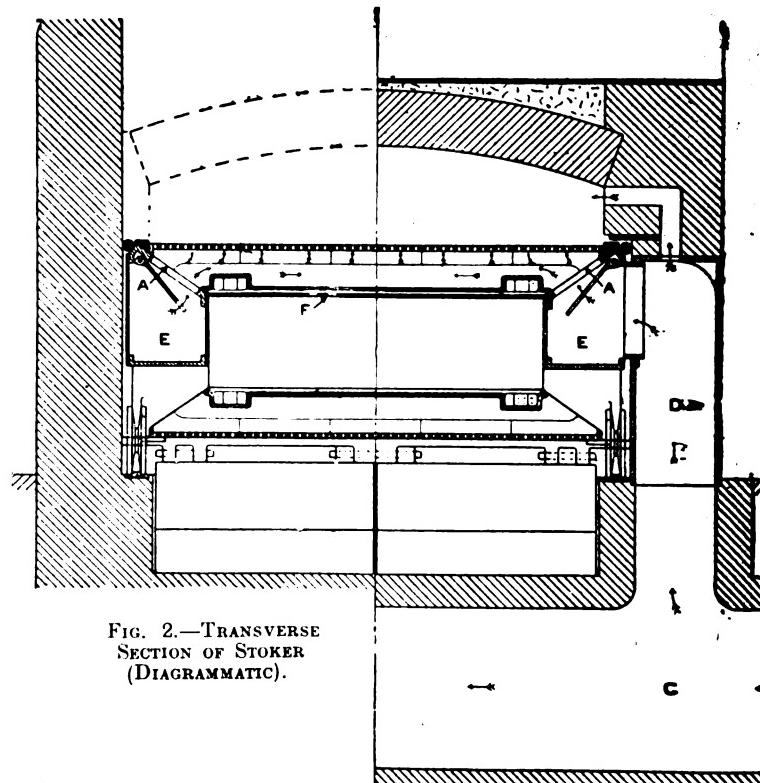

FIG. 2.—TRANSVERSE SECTION OF STOKER (DIAGRAMMATIC).

formance of these boilers may be obtained. This combination of the Underfeed stoker with the Prat draught system is certainly well worth close attention of central station engineers.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and be, for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,464.

It is desired to make up an adjustable resistance for occasional testing purposes in a small works, to give a voltage drop of 100 with a current of 5 amps. Describe a cheap method of doing this; state the material used, and the approximate cost of the resistance.

(Replies must be received not later than first post, Thursday, Nov. 4th.)

ANSWERS TO No. 1,464.

A three-phase supply of about 50 kw., chiefly for power purposes (induction motors), is taken through a static transformer, the primary pressure being 2,000 volts, and the secondary 200 volts. Discuss how many ammeters and voltmeters are absolutely necessary and how many desirable.

The first award (10s.) is given to "W. H." for the following reply:

As the installation is only a small one, an expensive or elaborate equipment is out of the question, and the instruments which may be considered as absolutely necessary for safety in working would be as follows:

Ammeter, A_1 , scaled to read 0-250 amps., connected in the secondary circuit in one line only, and preferably working off a current transformer.

Voltmeter, V_1 , scaled to read up to 250 volts, and connected across the secondary of the transformer at the bus-bars (or at the transformer terminals if no bus-bars are used).

Voltmeter, V_2 , scaled to read 2,500 volts, and connected to a single-phase potential transformer, the primary of the latter being connected across two poles of the outgoing side of the main oil switch.

This instrument V_2 is not absolutely necessary, but enables the operator to see at a glance whether the 2,000-volt supply is on the mains by simply closing the main oil switch feeding the 50-kw. transformer.

The ammeter A_1 enables the operator to check the total current on the secondary side of the transformer, while the voltmeter V_1 is necessary to see that the secondary is live and at the correct voltage, thus indicating with moderate certainty that the transformer is undamaged.

In order, however, to check the various motor circuits, and also to make certain that no unbalancing faults have occurred, the following additional ammeters and voltmeters are desirable:

Ammeter, A_2 , in one line of each motor circuit.

Voltmeter, V_1 , modified by the addition of a switch and connections to enable the operator to check the voltages on all phases.

Voltmeter, V_2 , modified by the addition of a switch and the substitution of three-phase potential transformer to read all three phases. This is really a refinement which may or may not be desirable, depending on the class of the installation.

Ammeter, A_3 , connected through current transformers on the H.T. side, and scaled to read 0-30 amps.

In this case, as the oil switch will probably have trip coils for operating in two phases, A_3 could be placed in series with them, and at a little extra cost a change-over switch could be installed enabling the current in each of the three lines to be read off.

The second award (5s.) is made to "E. B. P." for the following reply:

The absolutely essential ammeters and voltmeters in an installation such as the one under discussion may be put down as none at all, since the supply can be given quite well without them. However, in order to be able to note what, if any, fluctuations take place in the load, one ammeter may be regarded as essential; this instrument may be worked off the same current transformers that supply the watt-hour-meter, and provided with switches to allow of it being connected to any phase. If the watt-hour-meter is on the H.T. side, it will probably have only two current transformers, but in this case the overload relay will require three transformers, so that the current in the third phase can be measured by the ammeter without any difficulty. If the watt-hour-meter is on the L.T. side, it will most likely be a four-wire instrument, requiring a current transformer in each phase, to which the ammeter may be connected.

In considering the number of ammeters and voltmeters actually desirable, we must consider what measurements should be made. On the low-tension side we should be able to read the current in each phase, and also, perhaps, in the neutral wire; the volts between phases and the volts between each phase and the neutral. An ammeter should be installed in each phase of the low-tension side, and may be worked by current transformers or by the main current, as may be most convenient in the particular case. If a neutral ammeter be fitted up, it may have the neutral leads connected directly to it without a transformer, as the neutral wire will not be a very large one on an installation of this size. One voltmeter may be used, capable of being connected between any two phases or between any phase and the neutral by means of plugs or switches. On the H.T. side it may be considered desirable to have an ammeter capable of being connected to current transformers in each phase by means of suitable switches, or three ammeters may be used. If the load is very fluctuating, and if it is not intended to take and record frequent readings, the L.T. instruments should be of the recording type, so that any abnormality in the working of the electrical plant can be noted at any time.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Some remarkable successes have been attained from the recent experiments in wireless telephony in America, of which we gave some account last week. Telephone communication has now been achieved between Washington and the following points:—Panama Canal, 2,100 miles; San Diego, Cal., 2,300 miles; San Francisco, 2,500 miles; and Honolulu, Hawaii, 4,900 miles. It is interesting to note that this last communication had to traverse the whole continent of North America, going over land for a distance of 2,500 miles. The significance of this is that it is much more difficult to send wireless signals of any kind over land than over water. The fact that none of the towers involved in these tests, except that at Panama, might be considered as having antennæ of extraordinary power is further significant of the achievement. The tower at Honolulu, on which signals were received over a distance of 4,900 miles, is quite a small one, the equipment consisting of a span of wires about 250 ft. long, connecting the top of a smoke-stack 100 ft. high with the top of a water-tank about 80 ft. high.

The experiments have been conducted by the American Telephone & Telegraph Co. and the Western Electric Co., the wireless station of the U.S. Navy Department at Arlington, Virginia, having been lent to them for this purpose. It is said that wireless telephone messages have been received at the Eiffel Tower from this station. An interesting feature of the experiments is that it has been found possible by automatic apparatus to transfer messages from wires to wireless, and back again to wires. Standard office telephone instruments are stated to be suitable for sending and receiving, but technical details of the system are being withheld on account of a complicated patent situation.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 21st, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

20,176/14. **Electric Welding.** O. C. KNIFE and R. H. READ. A method of welding sheets, &c., consisting in bringing the parts to be united into contact, and applying a current by means of annular electrodes, in the centre of which an unconfined gaseous space is provided to equalise the heat. (Six figures.)

20,238/14. **Telephone Relay.** F. SCHIESSLER. The intensification of the weak undulating currents is effected by varying the conductivity of a medium placed between electrodes or preferably between condenser plates interposed in an intensifying circuit and the solid, liquid, or gaseous dielectric of which is ionised so that the ions form carriers of the intensified current. The displacement current produced by the superposition of the current to be intensified at the condenser producing an undulating current of higher intensity. (Six figures.)

20,920/14. **Ceiling Rose.** W. WILLIAMS, E. WARBRICK, and THE ANCHOR CABLE Co., LTD. A form of ceiling rose, the body of which forms a sealing chamber where the terminals can be covered with compound. (Ten figures.)

22,937/14. **Telephone Relays.** A. H. OLSSON and H. B. M. PLEIJEL. A telephone repeater with two induction coils so combined that one is best adapted for working with the speaking current and the other for working with the calling current. The latter is bridged by a capacity which acts as a high resistance to the calling currents, but transmits the speaking current without difficulty. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables, Insulating Materials, &c.: SHARP [Dielectric composition] 4,820/15.

Switchgear, Fuses, and Fittings: WILKINSON [Thermal switches] 23,775/14; TUCKER and CRABTREE [Switch covers] 2,968/15.

DIESEL ENGINE USERS' ASSOCIATION

At the October meeting of the Diesel Engine Users' Association, held at the Institution of Electrical Engineers, progress was reported with the scheme for insurance at Lloyds against breakdown of Diesel engines, and in connection with the Association's efforts to obtain better terms from the Inland Revenue authorities for a reduction in regard to depreciation on the assessment of Diesel engine plant for Income Tax.

The discussion on the question of "Lubrication of Diesel Engines" was then resumed. Mr. C. O. Milton (Borough Electrical Engineer, Maidenhead), observed that a careful consideration of the results obtained on various plants seemed to show that the consumption of lubricating oil on any particular engine was practically independent of the load at which it worked. He admitted that the consumption of lubricating oil must necessarily be somewhat higher when the engine was working on a heavier load, and consequently at a higher temperature, but his point was that the lubrication arrangements had to be generally set slightly on the liberal side, so as to suffice for such times as the engine might be called upon to do a heavy load, and that the increase in consumption of oil at the heavier load was comparatively negligible. He therefore arrived at the conclusion that a reasonable basis for comparison in the consumption of lubricating oil on various Diesel engine plants might be obtained by working this out in figures of gallons, or thousands of gallons, per B.H.P. per hour, taking for this purpose the maximum B.H.P. of which an engine is capable. Tests on the consumption of lubricating oil, to be of any value, must necessarily be taken over a long period of actual working, and in this connection he referred to the great importance of adopting the best means of filtering or treating the oil recovered for re-use. Mr. P. H.

Telegraphy and Telephony: SIEMENS & HALSKE A.G. [Telephone installations] 18,239/14; MUSSO [Transmission over circuits of high capacity] 18,242 and 18,243/14; RELAY AUTOMATIC TELEPHONE Co. and AITKEN [Manual and semi-automatic telephone systems] 20,453/14; MCGAURAN [Call recorders] 22,906/14; BULLERS, LTD., and DAGNALL [Joints for metal telegraph posts] 23,761/14; MARTIN (Turner) [Telephone apparatus] 2,148/15; TIGERSTEDT [Microphone] 5,174/15.

Traction: B.T.-H. Co. (G.E. Co., U.S.A.) [Catenary line suspension] 20,557/14.

Miscellaneous: B.T.-H. Co. (G.E. Co., U.S.A.) [Vacuum discharge devices] 15,788/14; J. A. SINCLAIR & Co. and SNELL [Magnetic compasses] 2,750/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Ignition: STANDARD Co. [Electrodes] 13,754/15; VAN DEVENTER [Ignition apparatus] 13,815/15.

Instruments and Meters: AUBERT [Meters] 13,869/15.

Switchgear: DEY [Controllers] 12,810/15.

Opposition to Grant of Patent

Opposition has been entered to a grant on the following specification:—

18,443/14. **Cab Signalling.** H. A. THOMPSON. An induction system of signalling with moving trains.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS, and TRANSFORMERS: SIEMENS BROS.' DYNAMO WORKS, LTD. [Control of motors in conjunction with flywheel converters] 15,231/06.

Switchgear, Fuses, and Fittings: M. G. DIAZ and A. YGRÉSILLON [Current limiter] 14,259/08.

Telegraphy and Telephony: T. T. BAKER [Facsimile telegraph] 15,918/09.

Traction: H. PIEPER [Petrol-electric vehicles] 15,178 and 15,180/06.

Miscellaneous: J. W. GILLIE [Magnetic compasses] 15,492/07; O. A. MYGATT [Ribbed glassware] 17,440/08; K. MAXAKER [Motor-driven centrifugal fan] 15,659/08; G. SAHMER [Electric lock] 15,991/09.

Smith considered that the low lubricating costs which had been arrived at on certain Diesel engine installations were to be attributed chiefly to the adoption of good methods of treating the oil. Mr. R. W. Lyle (The Hoffmann Manufacturing Company) was of opinion that the filtered oil should be allowed to stand for some considerable time before being taken for re-use, and that as a rule about 10 per cent. of new oil should be added to vivify it. The necessity of keeping a good body in the oil was of importance to prevent undue wear and tear on the bearings. He gave further useful information on several other points, and discussed the varying practice on different installations in connection with the removal of the carbon deposit from the top of the piston and from the rings as affecting the question of efficient lubrication of the cylinder. Mr. G. Porter (Borough Electrical Engineer, Worthing) gave figures of comparative tests which he had carried out on new oil and on oil after use in his Diesel engines, filtered or treated, which showed that the deterioration in its quality after a considerable amount of use was not very appreciable.

In the further discussion which followed it was generally agreed that the feeding of the lubricating oil to a Diesel engine could not in practice be regulated in accordance with the variations in load. Mr. C. Gould (Letchworth) stated that he found the consumption or destruction of oil increased considerably after the engine had been running for a long continuous period. Mr. H. L. Dixon (Leatherhead and District Electricity Supply Co.), said his experience was that the worn condition of liners resulted in a very definite increase in the consumption of lubricating oil, as well as in that of the fuel oil.

The next meeting of the Association will be held on Nov. 24th, when the subject of "Cracked Pistons" is to be discussed.

ALFRED GRAHAM & CO.,
ELECTRICAL ENGINEERS AND CONTRACTORS,
ST. ANDREW'S WORKS, CROFTON PARK, LONDON.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Coventry.—Notwithstanding the recent large extensions which have been put in hand by arrangement with the Ministry of Munitions, the increasing demands of firms engaged on war work render it necessary for further plant to be installed at an estimated cost of £30,000. The matter is to be discussed with the Ministry of Munitions.

Darlington.—The installation of a 3,000-kw. turbo-alternator is contemplated.

London: *Poplar.*—The Finance Committee of the L.C.C. recommends sanction to a loan of £8,688 for mains. Expenditure under the sanction is to be limited, during the war, to purposes for the furtherance of the war.

New Zealand.—The Napier Council contemplates extensions at its power-house at an estimated cost of £18,000.

Plymouth.—A number of mains extensions are to be carried out.

Rawtenstall.—The Electricity Committee do not seem disposed to adopt the view that all new consumers, except those engaged on war work, should be refused during the period of the war, and the question of increasing the generating plant is under consideration.

Salford.—Additional feeder cable for Trafford Road sub-station (£226); other services, Blackburn Street district (£900).

Miscellaneous

Dublin.—The Dublin United Tramways require a twelve months' supply of electrical accessories. Chairman. November 15th.

Grimsby.—House-service boxes, fuse-boxes, and fittings. Deputy Borough Electrical Engineer. November 4th. (See an advertisement on another page.)

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

London: *L.C.C.*—The tender of W. T. Henley's Telegraph Works Co. at £114 has been accepted for a main in connection with the lighting of refuges on the Victoria Embankment. Callender's Cable Co. tendered at £115 10s.; British Insulated & Helsby Cables at £117 10s.; and W. T. Glover & Co. at £117 15s.

The tender of Electromotors, Ltd., at £105 has been accepted for a motor in connection with the testing of electricity meters. The General Electric Co. tendered at £101 10s., or alternatively £139 10s.; and Variety's, Ltd., at £144 2s.

Hammersmith.—The existing contract between the Council and the British Electric Transformer Co. is to be extended to cover the supply for a period of three months of seven transformers of 50, 100, and 200 kw. capacity. The price is to be 7½ per cent. above the existing contract.

In order to maintain the full pressure in the Hythe Road area, 1,350 yards of new cable is to be laid. The tender of Messrs. Callender's Cable & Construction Co. at £1,312 has been accepted. There were seven other tenders varying in price from £1,285 to £1,400.

Newport (Mon.).—Ten tenders were received for the supply of converting plant, and that of the British Thomson-Houston Co. for a 264-kw. plant at £1,173 has been accepted.

Salford.—The tender of W. Geipel & Co. has been accepted at £130 15s. for 20,000 pairs of flame arc lamp carbons.

Arrangements for the Week.—*Friday, Oct. 29th.* University College. Lecture I., "Electric Heating and Electric Furnaces," by Prof. J. A. Fleming, F.R.S. 5 p.m.

Junior Institution of Engineers, 39 Victoria Street, S.W. "Electric Clocks," by W. B. Prince. 8 p.m.

Saturday, Oct. 30th. Association of Mining Electrical Engineers, Notts. and Derbyshire Branch. University College, Nottingham. Election of officers for session. Paper to be read: "The Use and Abuse of Oils on Mining Plant," by T. C. Thompson. 3.30 p.m.

Tuesday, Nov. 2nd. Institution of Civil Engineers. Presidential Address by Mr. Alexander Ross. 8 p.m.

Association of Supervising Engineers. St. Bride's Institute, Ludgate Circus, E.C. "Accumulators," by R. Rankin. 8 p.m.

APPOINTMENTS AND PERSONAL NOTES

Mr. J. F. Avila has been appointed Works Manager at the Birmingham Works of Simplex Conduits, Ltd. Some changes have recently been made, and the large amount of munition work the firm is engaged on necessitated Mr. Avila leaving London at very short notice. For the last nine years he has acted as London manager to the Company, and has been in touch with many electrical men in the London district. Mr. Avila regrets his hurried departure prevented him taking leave of the majority of them.

An engineer with electrical and mechanical training is required for the Imperial Bacteriological Laboratory, Muktesar, India. Salary, 350 to 400 rupees per month, rising to a maximum of 500 rupees per month. Three years' agreement. Director-General of Stores, India Office, S.W. November 1st.

Mr. J. H. Clifford, at present Junior Engineer-in-Charge at the Belfast Electricity Works, has been promoted to the senior position, and Mr. Girvan, switchboard attendant, has been promoted to succeed Mr. Clifford.

A switchboard attendant is required in the Wakefield Electricity Department. Borough Electrical Engineer.

Electrical Engineer wanted by British Dyes, Ltd. (See an advertisement on another page.)

Electrical Engineer wanted for small Irish town. (See an advertisement on another page.)

Plumber-Jointer wanted in Newport (Mon.) Electricity Department. (See an advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £87 10s. to £88 10s. (last week the same).

Openings for British Trade.—The weekly list of articles concerning which the Board of Trade Commercial Intelligence Branch has received inquiries includes metal filament lamps, corrugated packing material for electric lamps, and porcelain goods for electrical purposes.

Plant for Sale.—The liquidator of the Diesel Engine Co., Ltd., and Consolidated Diesel Engine Manufacturers, Ltd., offers for sale the whole of the remaining engineers' stores and other property at Ipswich of these Companies. Full particulars are given in an advertisement on another page.

LOCAL NOTES

Cheadle and Gatley: Bulk Supply.—The Manchester and Stockport Corporations are to be asked for terms upon which they will supply electricity to this district.

Grenock: Electricity Accounts.—After meeting capital charges and allocating £2,442 to depreciation, there was a net profit on the working of the electricity undertaking for the year to June 30th of £10,397. The number of units sold, viz., 14,207,575, show an increase of 21·4 per cent. over the previous twelve months, but in this connection it is to be remembered that the year includes eight months of the supply to Port Glasgow, which has had the effect of adding 1,632 kw. to the connected load.

Liverpool: Progress of Electrical Undertaking.—At the final meeting for the year of the Tramways, Electric Power &

Lighting Committee Mr. Russell-Taylor, who presided, reviewed the progress of the undertaking. The capital expenditure to the end of 1914 amounted to nearly 2½ million pounds, and the revenue for the year was £300,000. Since the taking over of the business of the old Company, the profits have enabled £862,128 to be repaid off capital, £390,000 has been carried to reserve, depreciation, &c., and £285,000 had been allotted to relief of rates, the contribution on this account for the current year being £25,000. The number of consumers now amount to 11,500, compared with 10,800 last year; whilst the total number of units supplied for all purposes amounted to 48 million. Special reference was made to the advantage, to small users, of motors on hire, whilst the application of the same principle to electric cooking and heating apparatus has had similarly beneficial effects.

Maidstone: Electric Wiring: Co-Partnership.—In his report for last year, Mr. E. E. Hoadley, the Borough Electrical Engineer, once more urges the need for powers to hire out cooking and heating appliances. Electric cooking, he says, is still throttled by the want of these powers, but, as no doubt Mr. Hoadley fully recognises, there is little prospect of any movement in this direction at the moment. Notwithstanding the difficulties occasioned by the war, the undertaking last year showed a net profit of £1,558, the largest surplus obtained since the works were started. All branches of supply show an increase except street lighting and tramways. The power units now form more than half the total output, and showed an increase last year of 31 per cent. over the previous year. Reference is also made in the report to the fact that the Department has been able to sell to the Government at satisfactory prices three 150-kw. sets, which were very much out of date for an undertaking of the size to which Maidstone has now grown. Nevertheless, the sets were exceedingly efficient for the purpose for which the Government wanted them, viz., wireless telegraphy. As the result the Electrical Department was able to put down larger and more economical plant, viz., a 1,250-kw. Ljungstrom turbine. At the end of the report the Committee is asked to give consideration to a co-partnership or bonus scheme.

Taunton: Cooking Apparatus.—At the last meeting of the Corporation, Alderman Van Trump protested against money being spent upon electric cookers for hiring out, on the ground that unless current could be supplied at ½d. per unit they could not compete with coal or gas.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Callender's Cable & Construction Co.—An interim dividend at the rate of 10 per cent. per annum, less tax, is declared on the ordinary shares for the June half-year.

Dick, Kerr & Co.—The accounts for the year to June 30th show a net profit of £36,100, which is £2,600 in excess of the previous year. The last dividend on the ordinary shares was 5 per cent. in 1910-11, but none has been paid since that. The directors, however, consider it in present circumstances inadvisable to do so now. The sum of £25,000 is set aside as reserve for contingencies, and after bringing in the balance from last year a sum of £18,300 is carried forward.—At the meeting on Thursday, the chairman, Mr. C. T. Cayley, said that the Company was living, as it were, from hand to mouth. All normal development had been stopped, and the energies of the staff had been transferred to the special requirements of the time. It was because the present conditions held out very little hope of large profits that the directors thought it wise not to recommend a dividend on the ordinary shares this year. The position with regard to profit on the Government work was doubtful at the moment. It was hoped that some reasonable profit proportionate to the efforts being made would be permitted.

Ferranti.—There was a trading profit for the year to June 30th of £37,230, but the balance for distribution is £18,789, which includes £2,050 brought forward. From this is deducted interest on the first mortgage debenture stock, interest on the five-year notes, and interest on bank loans, and, after adding £10,000 to depreciation reserve, a balance of £1,028 is carried forward. The results for the year show a falling off, but this is mainly due to the dislocation of export business due to the war and adverse monetary conditions. Extensions have been made to the Company's works in order to carry out additional work for the Government.

Companies Struck off Register.—The names of the following have been struck off the register of Joint Stock Companies:—Consolidated Electric Works & Appliances, Ltd.; Gamble's Patent Telephone Recorder Co. (Continental), Ltd.; Hayward's Heath Electric Supply Co., Ltd.; Radio & Electric Power Co., Ltd.

SUMMARY

THE first of a course of six lectures on electric heating and electric furnaces was delivered by Dr. Fleming at University College on Friday, October 29th (p. 442).

AT the Birmingham Local Section of the I.E.E., Lieut.-Colonel J. F. Lister delivered his Chairman's address on October 27th, on the subject of the application of electricity to military communications (p. 442).

THE Admiralty Recruiting Department points out the advantages of service in the Navy for skilled engineering workmen (p. 442).

MR. A. NICHOLS MOORE, the Newport (Mon.) Borough Electrical Engineer, makes an interesting contribution to our correspondence columns on the effect of enlistment on electricity undertakings (p. 443).

ADDITIONAL regulations have been made under the Defence of the Realm Act, giving increased powers to the Comptroller of Patents to prohibit publication of patents relating to war material, &c. (p. 443).

WE refuse to believe that the miners of Great Britain are cowards, no matter what resolution may be passed by the Miners' Federation (p. 444).

IN his Presidential Address to the West of Scotland branch of the Association of Mining Electrical Engineers, Mr. A. B. Muirhead criticised some of the methods used for underground electric lighting, and dealt with several other matters of interest (p. 444).

IN the Thomas Hawksley Lecture last week before the Institution of Mechanical Engineers, Dr. Dugald Clerk commented upon the doubtful possibility of any further increase in the present size of gas engines using reciprocating pistons. He expressed the opinion that developments in the gas turbine must be made to compete with the steam turbine (p. 445).

THE utility of surface earthing at collieries was severely criticised by Mr. W. Webster in a recent Paper before the Association of Mining Electrical Engineers (p. 445).

THE patent specifications relating to electrical working in mines published during the last month include two relating to shaft signalling and one describing an alarm bell for giving notice of movements of roof (p. 445).

AN instructive comparison between electricity and compressed air for coal-cutting was made in the course of a recent Paper by Mr. Sam Mavor (p. 446).

AMONG the subjects of specifications published by the Patent Office last Thursday were catenary contact line suspension, cable compound, thermal switches, and microphones (p. 447).

OUR Questions and Answers column this week deals with the effect on commutation of wrong connections between an armature and commutator (p. 447).

A DESCRIPTIVE account is given of an Edison electric motor lorry recently supplied to the Blackpool Co-operative Society (p. 448).

NEW plant is required at Gloucester (£25,000); gas-driven generating sets in New Zealand; mains at Stoke-on-Trent; and coal-handling plant at Sheffield and Ipswich; and three 100-k.v.a. transformers and switch panels at Erith (p. 449).

A LOAN for ordinary extensions has been refused at Wolverhampton.—A new 5,000-kw. turbo-alternator and two 1,500-kw. rotary converters have been started up at Bradford (p. 450).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D.,
COMMANDANT.

Drills, 6.15 to 7.15; 7.15 to 8.15.

(To-day) Thurs., Nov. 4th: Section III., technical. Section II., shooting, or working party.

Fri., Nov. 5th: Section IV., technical. Section I., squad or working party.

Sat., Nov. 6th: Company Parade, 2.30 p.m.

Mon., Nov. 8th: Sec. I., technical. Sec. III., squad or working party.

Tues., Nov. 9th: Sec. II., technical. Sec. IV., shooting or working party.

Thurs., Nov. 11th: Sec. III., technical. Sec. I., shooting or working party.

Fri., Nov. 12th: Sec. IV., technical. Sec. II., squad or working party.

Sections for technical drill will fall in at the Headquarters of London Electrical Engineers (T.F.), 46 Regency Street, S.W.

Sections for squad, signalling, shooting, and working parties will fall in at the new Headquarters.

Volunteers for trench work on Sunday, Nov. 7th, are requested to give early notice to their Section Commanders. It is hoped that as far as possible the men who attended on the 31st ult. will attend again on the 7th inst.

For "Arrangements for the Week" see p. 449.

ELECTRIC HEATING AND ELECTRIC FURNACES

THE first of a course of six lectures on electric heating and electric furnaces was delivered by Prof. J. A. Fleming, D.Sc., F.R.S., at University College on Friday last. He referred first to the various types of thermometer for the measurement of temperature, mentioning the standard nitrogen in quartz constant-volume thermometer at the International Bureau of Standards. Reviewing briefly Lord Kelvin's device of the measurement of absolute temperature by the reversible heat engine method, Dr. Fleming passed on to the main theme of his lecture, the measurement of high temperatures. He explained the Stefan-Boltzmann law, relating the energy radiated from a black body to its absolute temperature, and exhibited curves showing the distribution of radiant energy in the spectrum from violet rays to dark heat rays. Wien's law—that the product of wave length in microns of a ray of maximum energy, by absolute temperature, is equal to a constant (approximately 2,940)—was given, and it was shown how this principle, though not very convenient, could be used for the determination of temperature.

Turning attention to the commercial methods of high-temperature measurement, the lecturer reviewed the three different principles on which these were based, viz., the variation of resistance with temperature, the thermo-electric properties of materials, and the laws of radiation. In connection with these three principles, brief descriptions were given of (1) the platinum thermometer with compensating leads, now very much used, particularly for measurements of temperature from a distance; (2) the laws relating to thermo-electric power and the Holman formula for the E.M.F. in a thermocouple; and (3) the Féry radiation pyrometer. In the course of the lecture a very interesting instrument made by the Cambridge Scientific Instrument Co. was shown, known as a "thread recording thermometer." This was built in a similar manner to the ordinary recording instruments, except that instead of a pen moving over the paper, an inky thread was suspended between the pointer of the instrument and the paper, and a clockwork arrangement caused a lever to press the pointer on to the thread and paper once a minute, thus making the record by a series of dots, while the pointer was free to move without friction.

Five further lectures are to be given in this course, covering the following subjects:—Electric resistance heating and various types of resistance furnaces; arc furnaces; the applications of electric heating to the manufacture of various substances such as graphite, calcium carbide, aluminium, &c.; the electric production of iron and steel; and domestic heating and cooking.

APPLICATION OF ELECTRICITY TO MILITARY COMMUNICATIONS

ON Wednesday, October 27th, Lieut.-Col. J. F. Lister delivered his address as Chairman of the Birmingham Section of the Institution of Electrical Engineers.

For those who are not conversant with telegraph instruments, he said, it might be advantageous to say a few words about the instruments employed in the field. The Morse alphabet, which is used by all countries employing the Roman alphabet, is formed by various combinations of two distinct signals, on the principle that the most commonly used letters are formed by the shortest signals. In the instruments used for military purposes, the difference between the two signals is the difference of duration, one signal, known as a dash, being three times the length of the other, known as a dot. The interval between the component dots and dashes forming a letter is equal in duration to one dot, that between each complete letter forming a word to two dots, and that between words to three dots. The dots and dashes are sent by pressing a key, and thereby completing a circuit for the requisite duration of time. Using ordinary direct current, the signals are produced at the other end by the attraction of the armature of an electro-magnet, signals being read by the duration of time between the two clicks made by the armature on being attracted to the poles of the magnet, and on being released on the cessation of the current. A set made up in this way is known as a single current set, but it is obvious that to work a set of this description over any distance would entail prohibitive battery power, and therefore a relay is introduced at the receiving station. When a relay is employed, the coils of the sounder magnets are replaced by the coils of a relay magnet, which, when the circuit is completed, causes the armature of the relay to travel from one stop to another. It is possible by a method based on the principle of divided circuits to operate and receive at the same time at both ends of a single line; this is called duplex working, the method working at one end at a time being known as simplex. It is possible to duplicate duplex working, known as quadruplex, thereby causing four messages to be sent simultaneously—two in each direction—but in practice it is found

that the method is usually impracticable in the field owing to the high standard of insulation required in the lines. Furthermore, military traffic differs from ordinary commercial working, in that periods of greatest pressure are usually in one direction only. To enable heavy traffic to be dealt with on the lines of communication, Wheatstone is the most suitable system that can be employed, and full advantage is taken of these instruments. The principle of Wheatstone is, instead of the impulses being sent by an operator, perforated tapes are punched out, which, on being fed through the apparatus, cause the necessary impulses to be sent out, and to be printed in dots and dashes on a tape at the receiving end. Any number of clerks can be employed in punching the perforated slip, and a great deal of work, such as casualty lists, indents, returns, &c., can be punched during quiet times of the day.

The vibrator is an instrument which was specially invented for military work. In the vibrator system the signals, instead of being intervals of silence between sharp and distinct sounds, are given by long or short buzzes in a telephone receiver, separated by periods of silence. To produce these signals in the receiver a rapidly vibrating current is required—the period of vibration being about 150 to 500 a second, or those of sound waves. If the period is kept constant a more or less musical note is produced in the receiver.

For short vibrator lines it has been found necessary to provide single current sets, which are used whenever the cable line is down for some time, the cable itself being poled or raised from the ground by tying to trees. This is principally to avoid induction in the office, and, being on short distances, excessive battery power is not required.

Besides vibrator sets, a portable telephone and vibrator is used for brigade signalling, and for lineman's work on the lines. The additional condenser which is carried in the body of the instrument enables the lineman to work an ordinary circuit without interfering with signals which are being sent. A vibrator line can also be tapped at any point, and the signals read. When a vibrator is superimposed in an ordinary direct current set, it is necessary that there should be a certain capacity and self-induction in the line between the direct current and the vibrator sets; this is usually inserted specially by means of an apparatus known by the name of a separator.

The instruments used in a signal office are generally carried, made up, so that connections, upon opening an office, are reduced to a minimum. The incoming lines are usually laid either on to a commutator or terminal board, so that sets may be changed from one line to another without the necessity of re-connecting the whole office up again.

Lightning protectors are either carried on the terminal board or baseboard of instrument sets.

Besides the main work of the signal service which has been slightly sketched above, it is usual when a staff is stationary for some period to provide a small telephone system between the various offices, which system very often grows to a considerable size. Telephones are not suitable for sending messages when firing is going on.

Wireless forms a special branch of signal work, and it is not advisable at the present time to make any mention of the methods employed.

At the conclusion of his lecture Colonel Lister described with the aid of a highly interesting diagram the telegraphic arrangements of a recent battle, giving a realistic idea of the complicated and elaborate nature of the telegraphic service employed in the field.

ELECTRICAL WORKMEN FOR THE NAVY

THE Admiralty Recruiting Department wishes to make known more fully the advantages of service in the Navy for skilled engineering workmen. Transference from munition work to the Navy is not encouraged, but amongst those skilled mechanics who are not at the present moment engaged on munition work there must be many who would be glad to find an outlet for their technical abilities by becoming a member of the Naval Service. It is felt that if the opportunities and the requirements which exist in this respect were more widely recognised there would be no difficulty in keeping up the supply of electrical artificers and engine-room artificers who are needed by the Navy.

This branch of Naval Service has many attractions, not the least of which is the comparatively high pay received, which amounts on entry to nearly £2 per week, and which may be very considerably improved by good service. Such workmen enter the Navy with the rating of chief petty officers, they mess in the Chief Petty Officers' mess, and have the same opportunities for leave when they are in port. If they are sufficiently skilled, they are drafted at once on to a battleship, and their opportunities for advancement to commissioned rank are excellent.

During the period of the war men are accepted between the ages of 21 and 45. For rating as engine-room artificers, men who have experience and are competent workmen in the trades of engine fitters and turners, coppersmiths, boilermakers, and enginesmiths are required. An examination is usually held on entry, but in the case of a candidate who holds a Board of Trade certificate as a first-class or second-class engineer and

can produce certificates of character and ability from the works in which he has learnt his trade, exemption is granted. Engine-room artificers are entered as Chief Petty Officers, a position which carries with it many privileges.

Fitters, turners, and instrument-makers are required by the Navy as electrical artificers. Candidates for this rating are accepted for the period of the war between the ages of 21 and 45. The pay is also the same as engine-room artificers, and an examination in fitting and turning or instrument-making is imposed. Electrical artificers may be recommended for a practical course of training carried out on board the *Vernon*, which is moored at Portsmouth, or on board the *Defiance* at Devonport.

This avenue to naval life is certainly one not to be neglected by the skilled engineer. There is no quicker way of entering for actual service, and none which secures immediately better pay, prospects, and position.

CORRESPONDENCE

THE EFFECT OF ENLISTMENT AND MUNITION WORKING ON ELECTRICITY UNDERTAKINGS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In your issue of October 7th there appeared a contribution from a central station engineer on the above subject, some of the experiences detailed and the manner in which they have been overcome forming interesting reading.

Such experiences as your contributor brought to notice have, I am sure, by no means been exceptional to the general body of central station engineers.

Regarding the question of wages, the policy of giving war bonuses has been general throughout the country, and has, I believe, reasonably met the exigencies of the case. At the same time the want of municipal co-ordination in dealing with this question has given rise to considerable dissatisfaction in several instances and, in some, created labour difficulties which might have been avoided had a definite basis been decided upon by general conference through some central body, such as the Association of Municipal Corporations, before any decisions were made. So far as Newport is concerned, once the war bonus had been fixed, no further troubles were experienced. It was stipulated, of course, that the municipal bonus should not apply to those employees who had received an addition of wages, whether as a war bonus or general increase in the standard rate through the representation of any trades union or federation. Obviously, had the Corporation done otherwise—that is to say, given the municipal bonus to all—such action would have been tantamount to putting a premium on trades union labour.

I entirely disagree with the policy outlined by your contributor with the object of providing increased wages to those employees not enjoying the benefits of the general increase prevalent due to munition work; to deliberately find work and encourage overtime as compensation is a misguided policy, and one which will certainly reap its just reward when normal conditions are resumed.

As to the methods adopted to retain the staff, if they applied to engineers on the staff I am afraid it was rather a high-handed policy! I am not aware that there is any power existing at the present time under the Defence of the Realm Act or any Order in Council made thereunder which empowers Corporations by their chief officials to prohibit their engineering assistants leaving their present employ; such powers as do exist only apply to skilled workmen. I realised this difficulty a considerable time ago, and have since been in communication on a number of occasions with the Ministry of Munitions on this particular point, and they have now stated that the matter is having their careful consideration. It is naturally one upon which a decision cannot be hastily made. I think many engineers will endorse the view that there have been cases where assistants have taken advantage of the present conditions to endeavour to force the hand of the Corporation in the matter of increases. Personally, I have declined in every case to take any man who has applied for a vacancy unless he could produce a letter from his present employer to the effect that such employer had no objection to his applying for the vacancy and would permit him to leave if selected. In cases where I deemed it advisable to give an increase in salary rather than lose the services of the assistant, I had an agreement signed whereby they undertook not to apply for any other post for the period of the war.

Your contributor puts himself on the back in that he put his capital into buildings instead of reducing outstanding liabilities on obsolete plant. I am afraid his satisfaction is rather shortsighted. Present circumstances may apparently justify the policy, but surely such is not altogether to be commended. A prominent L.G.B. Inspector has on more

than one occasion strongly expressed himself on this point. The important question as to the way in which municipal undertakings not possessing ample reserve funds are going to deal with the question of mains and services extensions, now that the Treasury have restricted such expenditure to war purposes only, is one which I should have thought your contributor would have specifically referred to and dealt with. To the average undertaking I think the restrictions imposed on this account will be very serious, especially where those undertakings are in competition with gas companies. Many will be unable to provide the capital for these extensions out of revenue, with the result that valuable lighting and heating business will have to be declined, and such consumers once lost are not likely to be regained; moreover, in the case of new houses, this applies even more strongly.

When it is considered how many undertakings are dependent on their lighting and heating load, the seriousness of the position will be appreciated.

I agree with your contributor that the present time forms a magnificent opportunity for the pushing of power supply, not only the large supplies for munition works, but for that very important section the small workshop. In Newport we are to-day conducting a special campaign against obsolete gas engines, and I am glad to say that they are following each other to the scrap-heap with satisfactory regularity. The securing of this load will in some measure compensate for the very probable decrease after the war. I suggest it is rather a pity that your contributor did not omit his dissertation on international politics and finance; evidently by the time he had reached this point he had forgotten the precise subject upon which he set out to write. Exactly what connection there is between international politics and finance and "the effect of enlistment and munition working on electricity undertakings," I fail to appreciate.

In conclusion, I think that the contribution of October 7th, and the further little additions I have been able to add thereto regarding the many important matters that central station engineers have had to deal with since the outbreak of war, must suggest that a very excellent opportunity for the Incorporated Municipal Electrical Association to have been of real national service has been allowed to go by. Never was there such an opportunity afforded for the I.M.E.A. Commercial Development Committee to give a lead.

Yours faithfully,

A. NICHOLS MOORE,
Borough Electrical Engineer.

Newport, Mon., Nov. 1st, 1915.

WAR PATENTS

THE following additional regulations relating to war Patents have been made under the Defence of the Realm Act :—

Where an application has been made, whether before or after the date of the making of this Order, for the grant of a Patent or the registration of a design in the United Kingdom, and the Comptroller-General of Patents, Designs, and Trade Marks is satisfied that the publication of the invention or design might be detrimental to the public safety or the defence of the Realm, or might otherwise assist the enemy or endanger the successful prosecution of the war, he may delay the acceptance of the Complete Specification filed with the application for the Patent, or, as the case may be, the registration of the design, and in such case may by Order prohibit :—The publication or communication in any way of the invention or design; application being made for the protection of the invention or design in any enemy or neutral country; and application being made for the protection of the invention or design in any allied country or in any of his Majesty's Dominions without the permission of the Admiralty and Army Council.

No person shall apply for the grant of a Patent in respect of any invention or the registration of a design in any foreign country, or in any of his Majesty's Dominions, unless he has left at, or sent by post to, the Patent Office, a notice of his intention, together with a Provisional Specification, describing the nature of the invention or, as the case may be, a representation or specimen of the design, nor until after the expiration of one month from the time when such notice was given, and if during the said month the Comptroller-General is satisfied that the publication of the invention or design might be detrimental to the public safety or the defence of the Realm, or otherwise assist the enemy or endanger the successful prosecution of the war, he may make a like Order as in respect of cases in which application is made for the grant of a Patent or the registration of a design in the United Kingdom.

Before exercising any of his powers under this Regulation as respects any matter, the Comptroller-General shall consult with the Admiralty and Army Council and shall not act except upon the request of the Admiralty or Army Council.

ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

THE MINER'S OBJECTION TO ELECTRICITY

A STOCK subject for a resolution at any general meeting of miners is one complaining of the dangers of electrical machinery and calling for its suppression. At the annual conference of the Miners' Federation of Great Britain last month this was not forgotten. A delegate moved a resolution to the effect that electric coal-cutters should be prohibited by legislation, and this was passed, with power given to the executive—on the suggestion of the President—to widen its scope by including the use of electricity for all purposes as dangerous.

The reports of the inspectors for the various districts which we publish regularly in our columns show that the fatal accidents attributable to electricity are extremely few, and are almost invariably due either to neglect of rules or to carelessness on the part of the workmen. Moreover, the men themselves know this very well, and the real cause of their antipathy to electricity is that it is labour-saving. During the present time, however, it is a patriotic duty to encourage labour-saving devices of every description so as to release as many men as possible for military service.

We do not admit the danger of properly-used applications of electricity in mines; but even if such danger did exist, it is nothing to the danger which the men who have left the mines to fight in France, Flanders, and the Dardanelles have to undergo. Large numbers of miners have gone abroad to risk their lives in the country's service; coal is needed for the manufacture of the guns and ammunition they require and to supply the Fleet whose blockade will hasten the ultimate collapse of the enemy; every device which increases the output is of assistance to those who are placing themselves in the position of the greatest danger, and, if the risk of using it were a thousand times what it is, those who are obliged to stay at home should willingly incur it. We refuse to believe that the miners of Great Britain are cowards, no matter what resolution may be passed by the Miners' Federation of Great Britain.

ELECTRICITY IN SCOTTISH MINES

THE West of Scotland Branch of the Association of Mining Electrical Engineers recently held its opening meeting for the session at the Royal Technical College, Glasgow. The President, Mr. A. B. Muirhead, gave an inaugural address on the subject of "The Development of Electricity in the Scottish Mining Industry."

He said that a *résumé* of the position of this development would be useful at the present time, as we are now sufficiently far from 1911, when the present Code of Electricity Rules applicable to mining became law, and sufficiently near to 1920, when plant installed under the Code of 1904 must be removed from active service in order to comply with the law.

Scotland, said Mr. Muirhead, takes no mean place as a coal-producing country, as the yearly output has now reached about 42,500,000 tons. Mining development has been rapid, for in the past thirty years the output has increased by 22,000,000 tons. The coal may be said to be "hardly" won, for the mining conditions are hard and uncompromising. The difficulties incidental to Scottish mining have not always been understood and appreciated by legislators hailing from across the Border, who have seen fit to make laws to govern and direct all British mining operations as if there was only one colliery, one seam, and one set of conditions to be met. This reference to legislation—made in all sincerity and with good intent—might, Mr. Muirhead suggested, receive the attention of broad-minded men in

the Department concerned. The difficult nature of Scottish mining has resulted in a marked development in the use of electricity for power purposes, above and below ground. Electricity has been harnessed and used to counteract the natural obstacles to a greater extent than in any other division of the British coalfield, and the advantage of its extensive use is borne out by the fact that although the difficulties are great, the output per person employed above and below ground in the Scotland Division reached 321 tons in 1913 (reduced to 298 tons in 1914), whereas the next highest was in the Yorkshire and North Midland Division, where the output in 1913 was 286 tons per man (reduced to 258 tons in 1914).

Then followed a reference to the work done by the pioneers twenty years ago, to some of the difficulties they had to overcome, and the rapid progress they made. A winding equipment on the Thury series system was described, and was said to be mechanically and electrically first class. With regard to underground electric lighting, the speaker said this had a tendency to follow too closely the practice adopted in factories. Care had not always been taken to ensure that the types of cable and fittings were suitable for underground conditions. A result of using cables and fittings adapted for use above ground has been that the maintenance of electric-lighting systems underground has occupied the time of the colliery electrician to an even greater extent than the much more important power circuits required. Small unarmoured wires insulated with rubber tend to get damaged, and the cleats used for keeping each wire in its proper place are easily broken and displaced. The ordinary lampholder is not mechanically strong, and, for underground conditions, especially where dampness exists, it soon becomes a source of trouble. In some cases the wiring has been carried out in tubing, and owing to the condition of the atmosphere the wires have quickly deteriorated inside the tubing, causing breakdown and necessitating renewal. It has also been found somewhat difficult to keep the tubing continuous, with the result that damage to wires has occurred. The breaking of the continuity of the tubing sets up a serious source of danger. It has been customary to adopt as a lighting pressure the voltage in use at the colliery for power purposes, and Mr. Muirhead advocated that this practice should be continued for pressures up to 500 volts. It is better, he said, to make the cables and apparatus safe mechanically and electrically rather than resort to mixed-voltage systems, or to be under the necessity of installing motor-generator plant or step-down transformers, as the case may be.

Tables were given indicating the growth in output of coal in Scotland during the last forty years, the number of electrical and air-driven coal-cutters in use since 1910, and the number of electrical accidents from 1910 to 1914. After some comments on these tables, Mr. Muirhead concluded his address, saying that if—as an Association—they wished to render the best assistance in our power to the development of electricity in our coalfield, it is necessary that they should consider persistently and with unabated earnestness the training of the men who are called upon to handle electrical apparatus underground. The men employed on such work in Scotland do not differ materially from those in the other centres in the United Kingdom, in that they are inclined to neglect the most obvious precautions made for their safety. It is necessary to interlock handles of apparatus and devise "fool-proof" fittings, that they may be protected from the results of their own ignorance or carelessness. One still heard of men being injured when replacing fuses on circuits that have not been switched off; hence the necessity for interlocking fuse and switch boxes so that current must be cut off before doors can be closed. Each member of the Association should make it his business to point out consistently and constantly the little precautions, and the most obvious precautions, which must be taken to ensure that electrical plant will be handled properly below ground. By so doing they can support the colliery manager and follow up the work of the manufacturer and the designer of electrical plant. Thus each in his own particular sphere can further the important work of the development of electrical power in the Scottish coalfield.

THE WORLD'S SUPPLIES OF FUEL AND MOTIVE POWER

DR. DUGALD CLERK, in the Thomas Hawksley Lecture before the Institution of Mechanical Engineers in London on Friday last, Oct. 29th, took as his subject the supplies of fuel and motive power in the world, and pointed to some directions in which economies can be made which he anticipates should have the effect of doubling the possible industrial life of the world. The lecture has yet to be repeated at Manchester, Glasgow, Newcastle, and possibly one or two other provincial centres, and until this has been done the Institution does not consider that the lecture has been "delivered." Consequently for the present we are asked to give only an outline of the lecture, and it may be pointed out that owing to lack of time Dr. Dugald Clerk omitted on Friday to read certain notes which he had prepared upon large power stations.

Naturally most emphasis was laid upon the possible duration of our coal supplies, although references were made to the use of water power and oil. Incidentally we may mention that Dr. Clerk made no reference to the possibilities of home-produced alcohol for internal combustion engines. This, of course, does not come directly within the scope of electrical engineering, but it certainly is a subject to be taken into account in any consideration of the world's supply of motive power. As to the coal supplies in Great Britain, Dr. G. T. Beilby's estimate was quoted that if every possible use was made of electric power and gas engines employed for generating electricity no less than sixty million tons of coal per annum could be saved, whilst the same amount of work as at present could be achieved. That estimate, however, was before the rapid progress of the steam turbine, and Dr. Beilby has since revised his opinions as to the possibilities of gas-driven generators. Nevertheless, all the tendency, said Dr. Clerk, was towards proving that Dr. Beilby's original estimate was true. Various other figures were given of estimated economies in the use of coal, and the final result was the conclusion that the industrial life of this country, which necessarily depends upon our coal supplies, is capable of being doubled. In other words, our coal supplies could be made to last for 1,000 years instead of 500 years.

The lecturer conceded that anticipations in the development of large gas engines have not been realised, and that the practical difficulties of weight encountered when cylinders of a larger diameter than 15 inches were built had so far really proved insurmountable. To double the size of a gas engine cylinder involves doubling the total weight of the engine, and the extraordinary efficiency of the steam turbine at present has convinced gas engine builders that it is not worth while to proceed beyond cylinders of about 15 inches diameter. Consequently 5,000 h.p. was about the limit to which a gas engine at present could go, whereas a 5,000 h.p. steam turbine formed quite an ordinary unit for an electric power station. Dr. Clerk sees little hope of an indefinite increase in the size of gas engines using reciprocating pistons, and it was towards the gas turbine that engineers must turn if effective competition with the steam turbine is to be made. Although considerable work had been done upon the gas turbine, no success had yet been achieved. The thermal efficiency could be taken at about 15 per cent., and although in 1912 an efficiency of 23 per cent. was claimed, even this was not anything like the efficiency of the cylinder gas engine. At the end of 1911 no less than 6½ million h.p. of Parsons turbines were in use, mostly for electric power stations.

UTILITY OF SURFACE EARTHING CRITICISED

IN a recent Paper read before the East Scotland Branch of the Association of Mining Electrical Engineers, Mr. William Webster questioned the utility of surface earthing. He first took the case of a three-phase system with earthed neutral, assuming a 500-volt supply with the neutral point of the generator earthed through a resistance of 10 ohms. He assumed further that a fault occurred about 2,000 yards from the source of supply on a three-core 0·4 sq. in. armoured cable. The resistance of the armouring to accord with Special Rule 125 (b) of the Electricity Regulations would be about 0·24 ohms. The potential difference between the neutral point and one main would be 290 volts, so that taking account of the armouring and earthing resistance the current passing would be about 28 amperes. The potential difference between the fault and the station end of the armouring connected to the earth-plate, however, would only be six volts. Thus, even assuming the earth-plate to be making the best possible contact, it would not be carrying any appreciable current, and little if any shock would be felt by a person coming in contact with the switch or motor casing or armouring at the fault. If there were no resistance in series with the neutral point, the current would be considerably increased, the potential differences between the fault and the station end of the armouring would be increased also, and severe shock might be received on touching the casing. On disconnection of the

earth-plate no increase of the potential difference between the fault and the station end of the armouring would take place in either case, but the resistance between the latter and the earth would be considerably increased. This would mean that the potential difference between armouring and earth at the fault would be decreased. Therefore, the author contended that from a safety point of view the earth-plate is useless. He also remarked that in the daily working of a colliery where fuse-bridges have to be withdrawn and replaced direct contact with a live part may occur, and, with the neutral point earthed as in this case, a full voltage of 290 volts would be received.

The author next considered a three-phase system not earthed at the centre, but with ordinary surface earthing of the apparatus and armouring. In this case if a fault occurred no current would pass unless there was another fault on one of the other phases, when the trip would open the circuit. If the latter lags in any way, there may be momentarily a dangerously high voltage between the two points of the armouring, which, however, would not be reduced by the presence of the earth-plate.

The case of 3,000-volt transmission down the shaft was next considered, assuming transformation to 500 volts at some convenient station underground for haulage motors, &c. In these circumstances the shaft cables would be of much smaller section than the low-tension main feeders. According to the Rules, the low-tension apparatus must be earthed at the surface, and the conductivity of the armouring of the shaft cable would have to be reinforced by a separate wire to bring the conductivity up to 50 per cent. of the low-tension core. Nevertheless, it is very doubtful whether any of the leakage current from a fault on the low-tension side would pass through the surface earth-plates.

Lastly, a D.C. 500-volt system was considered with the ordinary earthing on the surface. Assuming 0·3 sq. in. twin-core armoured cables feeding two pits, each feeder being 2,000 yards long, the resistance of the armouring would be about 0·3 ohms for each cable. If a fault were to occur at point A at the far end underground in one of the pits, no interruption of the supply would take place, and there would be no danger of shock. If another fault were to occur at point B in the other pit and on the opposite pole, a potential difference would be set up between A and B, and, with the motors on concrete foundations, the resistance between A and B would be fairly high. The leakage current would flow through the armouring from A to B, and the potential difference between A and B might be 100 volts or more, depending on the nature of the faults. To reduce this, the resistance between A and B through the earth would require to be decreased at or near these points, and owing to the difficulty of making a good earth there, even this might prove futile. Again, as in the three-phase systems, the surface earth-plates would not be brought into action.

On the other hand, the author admitted that if the armouring is not carried right through, his arguments do not necessarily hold, for instance, in systems where the tails entering a motor are left open, where there is open type switchgear where the wiring could come in contact with the earth, or where unarmoured cables are used. In such cases earth-plates at the surface do come into active operation.

Although there is no compulsion to instal earth-plates underground, it is to be recommended in many cases.

ELECTRICAL MINING PATENTS FOR OCTOBER

IN Specification No. 19,854 of 1914, the Sterling Telephone & Electric Co. and H. W. Barclay describe a signalling system for mines, in which visual signals distinctive of a number of different signalling stations are each adapted to be put in circuit upon the commencement of a signal from any other station, while the signalling apparatus proper, capable of giving audible and visual signals, is common to all the signalling stations, and can be appropriated by any one of them, and any signal given is cleared by the commencement of a fresh signal, whether by the same or another signalling station.

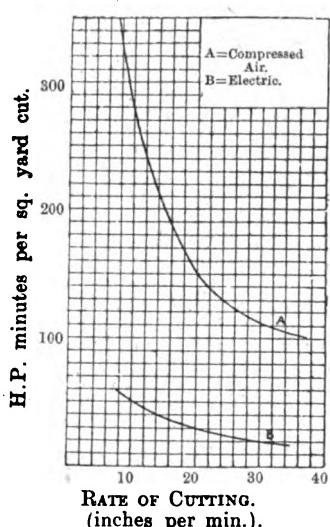

Another specification relating to shaft signalling is No. 17,000 of 1914, by G. F. Black. In this improved system the hand-signalling lever and its connections to the bell and indicator are arranged so that the transmission and wiping out of the signals are both effected by the same lever, the movement of which when giving a fresh signal wipes out the previous one.

J. P. O'Donnell describes in Specification No. 1,119/15, communicated by G. D. Hodges and D. Smith (Johannesburg), a form of alarm bell for giving notice of movements of

roofs, &c., which is self-contained in that the bell, battery, &c., is attached to a readily adjusted telescopic bar which can be placed in any gallery, and will make a contact to ring the bell on a movement of the roof of a predetermined amount.

COMPRESSED AIR v. ELECTRICITY FOR COAL CUTTING

IN the course of a Paper on "Compressed Air for Coal-cutters," read recently before the Institution of Mining Engineers, Mr. Sam Mavor included the curves below to illustrate how sensitive to change of load is the efficiency of a compressed air coal-cutter, and how much more its power efficiency in operation is dependent upon the skill of the driver than is the case with an electric machine. The curves are drawn from results of actual tests, and the compressed-air and electric machines are represented on the same scale of energy, the compressed air, and the electricity supplied to the machines being reduced to the equivalent brake horsepower hours. The form of the curve of the electrically-driven machine may be taken as closely approximate for all electrically-driven coal-cutters. The curve of the compressed-air machine will not bear such wide application; it refers to a particular machine, and, although fairly characteristic, its form is only to be taken as roughly representing compressed-air machines in general. The positions of the curves on the scale depend—other things being equal—upon the hardness of the materials cut by the machines. The two machines tested worked under similar conditions, cutting in easily-holed coal, and the two curves given are therefore comparable both as to their forms and their positions on the scale. The favourable position of the electric machine on the scale is due to its working in a closed circuit, and having no exhaust pipe from which to vomit unused a large proportion of the energy supplied to it.

Rights of Patent Licensees.—In the Court of Appeal on Oct. 20th, before the Master of the Rolls, Lord Justice Banks, and Lord Justice Warrington, judgment was given in an action by the Diamond Coal Cutter Co. against the Mining Appliances Co., which raised an interesting point in patent law, not only with regard to mining but generally. The Mining Appliances Co. are exclusive licensees for a coal conveyor operated electrically. The owner of the English patent is a German residing in Germany, and the action by the Diamond Coal Cutter Co. was to restrain the Mining Appliances Co. from issuing threatening circulars to their customers against using alleged infringements of this patent. The point put before the Court was that by this circular, the licensee claimed all the rights of a patentee, which it was argued the Patents Acts do not confer. The Master of the Rolls in giving judgment, said that the word "patentee" is defined in the Act as a person for the time being entitled to the benefit of a patent, although it was clear he thought that a mere licensee was not a patentee within the meaning of Section 36 of the Act. The point at issue was whether the defendants had by their circulars brought themselves within this Section. Mr. Justice Eve in the Chancery Court had refused to grant an injunction. The documents in question, he said, stated that the Mining Appliances Co. were not the patentees, but were exclusive licensees, and any proceedings which were threatened against users of alleged infringing apparatus were expressly stated to be under their license. That being so, he did not think the Company was liable to an action under Section 36 of the Patents Act, which defined the rights of a patentee. On the other hand, they might be liable to action at common law, but only if malice could be proved. The other Lords Justices agreed.

Association of Mining Electrical Engineers.—The annual meeting of the Association of Mining Electrical Engineers was held in Manchester early last month, when the awards for Papers read during 1914-1915 session were presented. A committee was appointed to investigate the financial position of the Association, and the President, Mr. R. Holiday, called attention to the need for carrying on the work of the Association, notwithstanding the interference with the ordinary course of things which the war had involved. He also mentioned that a scheme for holding classes at certain collieries, at which attendance would be open to members and non-members of the Association, was to be tried.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 28th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

20,557/14. **Overhead Conductors for Electric Railways.** B.T.-H. Co. (*G.E. Co., U.S.A.*). A catenary system of contact line suspension, in which several conductors are suspended side by side from one messenger wire with the points of suspension arranged in recurrent succession. (5 figures.)

23,778/14. **Thermal Switches.** G. WILKINSON. Switches actuated by the expansion of mercury in which a chamber of glass envelops the capillary tube where the make and break takes place, filled with inert gas and sealed by immersion in mercury. (3 figures.)

4,820/15. **Cable Compound.** R. C. SHARP. A compound for filling cable conduits, &c., consisting of pitch or bitumen, to which is added while in the molten state finely ground and pulverised spent shale.

5,174/15. **Telephone Transmitter.** E. M. C. TIGERSTEDT. A microphone with a tubular diaphragm of non-conducting material with electrodes formed of separate annular segments, adjacent segments being of opposite polarity, and the space between them and the diaphragm being filled with granular or powdered carbon. (3 figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Electrometallurgy and Electrochemistry: WEBB and WILLIAMS [*Electrolytic bleaching*] 20,714/14.

Heating and Cooking: QUAIN [*Electric heaters for ironing and other purposes*] 20,721/14.

Ignition: FEENY (*Fabrik Elektrischer Zunder Ges.*) [Blasting fuses] 14,224/14; WILSON and SHEPHERD [Ignition apparatus for internal combustion engines] 20,776/14.

Switchgear, Fuses and Fittings: PICKETT [Switching devices] 14,146/14; HEATE & KEITH [Automatic tumbler switches] 20,896/14; OTTINETTI [Press-button switches] 2,787/15; LANDIS & GYA A.G. [Motor actuated switches] 9,015/15; WALLACE NOVELTY Co. [Lamp stand] 9,509/15; STEVEN [Switches for lift control] 9,806/15.

Telephony and Telegraphy: MARKS (*International Quadruplex Co.*) [Telegraphy] 16,343/14; MUSSO [Transmission of impulses over circuits of high electrostatic capacity] 18,511/14; LAVALLEY [Telephone locks] 10,054/15.

Traction: SMYTH [Car lighting] 22,062/14, 6,715/15; ALBION MOTOR CAR CO. & MURRAY [Car lighting] 11,139/15.

Miscellaneous: BROWN [Signals] 22,199/14; TULLOCH [Electric ordnance] 2,636/15; NEWELL and MARX [Electromagnetic extraction of foreign substances from paper pulp] 2,865/15; MEIROWSKY & Co. [Condensers] 5,498/15; SIEMENS & HALSKA A.G. [Fire alarms] 6,457/15; WILSON [Condensers] 10,251/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Heating and Cooking: HELLER [Cooking] 14,405/15.

Traction: BRITISH WESTINGHOUSE Co. [Combined engine starter and ignition arrangement] 13,985/15.

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, Motors, and Transformers: SIEMENS BROS. DYNAMO WORKS and W. PARKER [Prevention of sparking in D.C. turbo-generator] 16,051/07.

Heating and Cooking: H. J. DOWSING [Combined radiators and convectors] 15,591/02.

Incandescent Lamps: B.T.-H. Co. (*G.E. Co., U.S.A.*) [Metallic carbon filaments] 14,867/08.

Switchgear, Fuses, and Fittings: SIEMENS BROS. DYNAMO WORKS and E. SCHAPP [Controller contacts] 16,537/09.

Traction: SIEMENS BROS. DYNAMO WORKS, LTD., and L. DE M. G. FERRIERA [Railway points and signals] 14,697/08.

Miscellaneous: J. S. STEVENS, C. G. MAJOR, E. C. and P. H. STEVENS [Electric lift control] 15,764/02.

tions be fitted to either type, and if so, is it advantageous to do so?—“Enquirer.”

(Replies must be received not later than first post, Thursday, Nov. 11th.)

ANSWERS TO No. 1,465.

A 20 h.p. D.C. motor has its armature lap wound with six conductors per coil, arranged in the slot in this order: 1, 2; 3, 4; 5, 6; i.e., two side-by-side and three deep per coil. In replacing a faulty coil the conductors may have been connected to the commutator so as to change their order numerically in the same slot thus: 2, 1; 6, 5; 4, 3. Would this change be detrimental to the running of the machine, enough to cause sparking?—“BOOSTER.”

The first award (10s.) is given to “Y. Z.” for the following reply:—

The question does not contain enough data to enable a perfectly definite answer to be given, but some general considerations may be set out. There is no statement as to whether there are equalising connections on the armature or not. On so small a motor as 20 b.h.p. they would, perhaps, not be fitted, and hence any results in the shape of cross-currents due to lack of symmetry would appear at the brushes, and, if sufficient in magnitude, would cause some sparking. The question does not make clear either whether the expression “coil” denotes all that is between two commutator parts or if it means that the six conductors fill up half the slot and are connected actually to more than one commutator segment, i.e., to two, three, or six segments. If the whole coil of six turns is between two segments, then the actual arrangement of the wires should not make any material difference, as all the six turns are in series, and the total E.M.F. of the coil would be equal to the E.M.F. of any other coil, and in phase with the coil at the opposite side of the armature which is commutated at the same time. As a 6-turn lap winding is somewhat unusual, however, it seems more likely that there are two, three, or six segments

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under “Answers to Correspondents,” or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a “nom de plume,” but, both in the case of questions and answers, the competitor’s real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor’s decision is final.

QUESTION No. 1,467.

Explain the relative advantages and occasions for using duplex re-entrant (symbol ) and duplex non-re-entrant (symbol ) windings on direct-current armatures. Can equalising connec-

to each coil. In that case it should be remembered that the commutation characteristic of the various conductors depends on their position in the slots, those which are most embedded, and surrounded by other conductors which are at the same time electrically under the brush, having the most difficult commutation. The conductors at the side of the slot which first comes up to the brush have an easier characteristic than those which are commutated later in the slot, because the latter have mutual induction (between themselves and the conductors earlier in the slot, not yet emerged from under the brush) coming into their commutation equation, and tending to increase the reactance voltage of the later commutated coils. Thus if 1, 2 are at the top of the group, 3, 4 in the middle, and 5, 6 at the bottom, then if 1, 3, 5, which form a vertical side of the group, come first to the brush, the difficulty of commutation will probably increase as these various coils come under the brush, although the quantitative difference cannot be stated owing to lack of data. Coils normally arranged should therefore produce groups of commutator segments which will show increasing tendency to spark, these groups consisting of pairs, threes, or sixes, according to the number of segments per coil. If now the coils have got displaced, it is conceivable that the irregular group may combine with the adjacent normal group so as to upset the succession that two bad segments come together, which, coming under the brush together, might cause a distinctly increased tendency to spark at that point. This can only be generally stated owing to the lack of detail already indicated. Further, it is clear that all the six conductors are not exactly in phase, and if they are displaced so as to be unlike the coil at the opposite side of the armature (assuming a four-pole machine) which is being commutated at the same time, it is conceivable that there might be enough difference in phase between the two sides of the armature to cause a cross-current, which in the absence of equalisers might set up sparking.

Speaking generally, any lack of symmetry is bad in a lap-wound armature, and may set up irregularities which become cumulative in their effect, and result in flattening and sparking, but it must be candidly confessed that so slight an irregularity as the one described in the question, as here understood, does not seem as though it should be sufficient to cause serious trouble unless the motor is, to begin with, very sensitive as regards commutation, and ready to be upset by some small cause. If sparking does occur it can only be because of some such cause as has been generally indicated. If equalisers are fitted, then out-of-phase effects should not make themselves visible at the brushes, and the matter would then resolve itself into one of reactance voltage.

Possibly these notes, necessarily vague on account of lack of information, may help the questioner to solve any difficulty that may have arisen. It is a pity he has not even stated the voltage of the motor.

The second award (5s.) is made to "W. H." for the following reply, which is slightly abridged:

By reversing the positions of 1 and 2, 3 and 4, 5 and 6, it results in the coil connected to a particular segment being commutated in a slightly different position relatively to the corresponding coils in the other portions of the armature, providing there are more than two poles.

If there are only two poles the effect on the sparking will be negligible.

If there are more than two poles there will be some appreciable increase in sparking unless the machine is fitted with commutating poles. In this event the machine being only a small one, and consequently not being anywhere near the limit of reactance volts, the sparking would not be visibly increased, although slight blackening of the commutator may occur owing to under-brush sparking caused by circulating currents.

It is suggested that the relative positions of 3-4 and 5-6 have also been changed; this it is rather difficult to imagine may happen, as it means two badly wound coils with the conductors crossing, but in any case the result as regards sparking would be *nil*, as the position of the commutated coil relatively to the field is not altered.—W. H.

Obituary.—The death took place on Monday of Sir Arthur Rucker, F.R.S., late Principal of the University of London, at the age of 67.

EDISON ELECTRIC MOTOR LORRY

THE Manchester branch of Messrs. Drake & Gorham, Ltd. (47 Spring Gardens, Manchester), sends us some interesting particulars of a new 30-cwt. electric motor lorry by Edison Accumulators, Ltd., for whom they are agents in the North of England. The lorry, of which we give an illustration, is built on a chassis known as the Edison Accumulator Model "G. M." The transmission from motor to differential countershaft is noteworthy, being effected by special flat spring-tempered steel blade, flexible and self-aligning, fitted with bronze-bushed eyes working on hardened pins provided with grease-cups, and large square slip joint at motor end. Then from a jack-shaft to rear wheels the driving is by sprockets and roller chains.

The accumulator consists of 60 Edison cells, type "A," with a capacity of 225 amp.-hours at the five-hour discharge rate, the total weight being 1,260 lb. It is housed below and behind the driver's seat. The motor rating is 72 volts, 40 amps., 900 r.p.m. It is a motor of the enclosed type,

specially designed to have maximum efficiency with the accumulator characteristics. The commutator is slotted in a manner similar to the standard street railway type. The shaft is mounted on ball bearings.

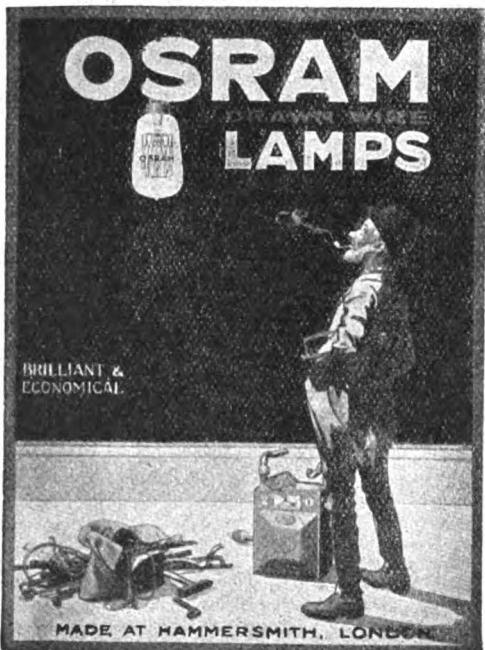

The controller is of the continuous torque drum type, and gives five speeds forward and two reverse. It is operated by handle above, and concentric with the steering-wheel. It is mounted on the front of the car under a rainproof hood, which also covers an ampere-hour meter, safety switch, light switches, and switchboard. The resistances are of the standard grid type.

The car operates over a radius of 40 to 50 miles per charge, at an average speed of 11 miles per hour when fully loaded, an extra 15 miles being possible by giving the accumulators one hour's boost at twice normal rate. The makers claim that the average power consumption of a lorry of this type recently delivered to the Blackpool Co-operative Society, is under 0·7 unit battery input per mile run, and as the Society generates current at about ½d. per unit, the power cost for a 20 miles' round trip is only 7d., compared with a fuel cost of 3s. 8d. for a petrol lorry that has been doing similar work for the Society. The fact that the Society has published a eulogistic notice of the vehicle in their official journal, and have placed an order for a second vehicle, certainly points to their satisfaction with the results obtained with the present one.

Germany's Shortage of Copper.—According to a Reuter telegram from Copenhagen, the Kiel municipality has ordered the breaking up of the tramways in some of the less busy parts of the town, the main object apparently being to obtain the copper from the cables. The work of demolition has been started in three streets, and already about 7 tons of copper have been obtained for war purposes. It is added that similar steps are anticipated in a number of other German cities.

OSRAM ART

THE latest design for advertising Osram drawn-wire lamps is exceedingly effective. Our reproduction of it in black and white does poor justice to the original, which is strikingly coloured. The expansive rich blue background and the stone colour foreground make a very charming setting. The attitude, features, and colouring of the "gas-fitter," together with the

humour of the design, produce a general effect which is both impelling and pleasing.

Posters and showcards, lithographed in ten colours, will shortly be available, and in a few days' time a small folder and a quarto size four-page list of Osram drawn-wire lamps will be ready for distribution. In these two cases the design is printed in four colours on the outside front page.

CATALOGUES, PAMPHLETS, &c., RECEIVED

"WRENDAL" METAL FILAMENT LAMPS.—A leaflet from L. Andrew & Co. (2 Whitworth Street West, Deansgate, Manchester), gives particulars and prices of "Wrendal" British-made lamp and "Capella" carbon filament lamp. The consumption of either the low or high voltage types of the metal filament lamp is quoted at 1½ watts per British c.p., with an average life of 2,000 hours, whilst for the carbon lamp the consumption is given at 3½ watts per c.p., and the life 1,000 hours for low voltage and 700 hours for high voltage.

EDISWAN ACCESSORIES AND FITTINGS.—A 10-page leaflet from the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex), deals with every detail in electric light accessories and fittings which go to make up the complete article.

OSRAM PAINTING BOOKS.—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), has tapped a really novel source of interest in a series of children's painting books. Three of these have been issued containing on the left-hand pages a coloured drawing and on the corresponding right-hand pages the same drawing in detail. The pictures illustrate rhymes which, in simple fashion, sing the virtues of Osram lamps. The first deals with the lights of 1830, 1890, and 1915, viz., the candle, gas, and the Osram lamp respectively. The second deals with the story of how an Eskimo girl discovered what she perversely mistook for the sun, and the third relates how the lesser light which rules the night has been forgotten by children who live in cities lighted by Osram lamps. The drawings have a quaintness which will appeal to the children—and, be it said, to the parents also—and should result in giving a happy impression of the Osram lamp. These painting books are being distributed direct among electric light consumers, and have already proved very popular. This is a scheme from head office to supplement local advertising through contractors.

MAGNET FIRES, COOKERS, IRONS, &c.—Folders from the General Electric Co. Ltd. (67 Queen Victoria Street, E.C.), give particulars of the Company's electric fires, cookers, irons, kettles, toasters, and hot plates. These will be supplied to electrical contractors, over-printed with their name, on application to the Company.

"WOTAN" DESK PAD.—We have received from Messrs. Siemens Bros. Dynamo Works, Ltd. (38 and 39 Upper Thames Street, E.C.) an exceedingly useful Wotan desk pad. This is made of oxidised metal, and is provided with a spring clip so that the separate sheets of the writing pad itself can be readily removed or replaced as occasion requires.

TENDERS INVITED AND PROSPECTIVE BUSINESS**Generating Stations, Sub-Stations, Mains, &c.**

Erith.—Three 100-k.v.a. transformers and switch panels are required.

Gloucester.—Application is to be made for a loan of £25,000 for plant extensions to meet the demand for power from the Gloucester Paper Mills.

Ipswich.—An inquiry was held last week concerning a loan of £3,100 for coal bunkers and coal-handling plant at the electricity works.

Middlesbrough.—It is proposed to instal an automatic regulator at the electricity works and to carry out certain alterations to the cables for taking the entire supply from the Cleveland & Durham Electric Power Co. This scheme substitutes one put forward a short time ago for the installation of a large booster.

New Zealand.—The Napier Council requires two gas engines with generators, switchboard panels, cables, &c. Tenders to Clerk. November 9th. This information, of course, is only of value to firms who can cable agents.

Sheffield.—Coal-handling plant is to be installed at Neepsend at an estimated cost of £6,000.

Stoke-on-Trent.—Application is to be made for a loan of £1,000 to cover prospective expenditure on distributors, &c., during the next six months.

Wolverhampton.—A loan of £1,365 has been sanctioned for mains extensions to deal with firms engaged on war work.

Wiring

Barrow-in-Furness.—Victoria Schools, Oxford Street. Borough Electrical Engineer. November 8th.

Latchford (Cheshire).—Electric lighting for St. James's Church. Rev. H. B. Firth, Vicar.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Cardiff.—New public hall. Architects, Willmott & Smith, 29 St. Mary Street.

Coventry.—Extensions to factory, Gosford Street, for Messrs. Hotchkiss.

Rochdale.—Military hospital.

Miscellaneous

London: H.M. Office of Works.—Supply of electric lamp-holders. Controller of Supplies, 18 Queen Anne's Gate, S.W. November 8th.

APPOINTMENTS AND PERSONAL NOTES

The Pembroke (Ireland) Council requires a temporary shift engineer acquainted with a three-wire D.C. station. Applications to Clerk. November 5th.

An electrician is required for Gold Coast Government Waterworks. Salary £300, rising to £350. The plant consists of a 500-volt suction gas generating set with electric motors. Applications to Messrs. Hunter, Duff & Middleton, 17 Victoria Street, S.W.

The salary of Mr. J. R. Hall, Mains Superintendent at Accrington, has been increased from £140 to £146 10s.

The Southern Command of the War Department requires various electrical workmen. (See an advertisement on another page.)

Arrangements for the Week.—**Friday, Nov. 5th.** University College, London. Lecture II. "Electric Heating and Electric Furnaces," by Prof. J. A. Fleming, F.R.S. 5 p.m.

Monday, Nov. 8th. Newcastle Section, I.E.E. Mining Institute. Chairman's Address by P. V. Hunter. 7.30 p.m.

Tuesday, Nov. 9th. Scottish Section I.E.E., 207 Bath Street, Glasgow. Chairman's Address by D. A. Starr. 8 p.m.

Thursday, Nov. 11th. Yorkshire Section I.E.E., Philosophical Hall, Leeds. Chairman's Address by H. H. Wright. 7 p.m.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £89 to £90 (last week, £87 10s. to £88 10s.).

Bankruptcy.—The last day for receiving proofs in the bankruptcy of Herbert Page, electrical engineer, trading as Smeeton & Page, 63 Queen Victoria Street, is November 6th. The trustee is the Official Receiver, Bankruptcy Buildings, Carey Street, W.C.

Liquidation.—A compulsory winding-up order has been made with regard to the Adnil Electric Co. The position of this Company was discussed in the action by the British Traders' Association, reported on p. 246 of our issue for June 10th.

Agencies.—A Montreal firm wishes to represent United Kingdom manufacturers of electrical equipment for the mining industry.—A firm in Viborg (Russia) wishes to get into touch with United Kingdom manufacturers and exporters of electrical plant, fittings, and machinery. Further particulars at 73 Basinghall Street, E.C.

LOCAL NOTES

Birmingham: Temporary Power Station.—It is anticipated that the temporary power station which was described in our issue for August 19th, p. 346, will be completed in about three weeks' time. Pending this, the Electric Supply Committee ask all consumers to use as little current as possible between 5 and 6 p.m.

Bradford: Inauguration of New Plant.—Some of the new plant mentioned in our account of the Bradford Electricity Department on p. 434 of our last issue, was started up on Thursday. This consisted of a 5,000-kw. turbo-generator and two 1,500-kw. rotary converters at the Valley Road power-house. A third rotary converter set is to be installed. At the subsequent luncheon some reference was made to the contract placed for a Bergmann turbo-generator which caused so much controversy at the time it was made. The Chairman of the Electricity Committee recalled the fact that the steam consumption figures for this German turbo-alternator were 10 per cent. less than the best English tender, and added that it had been determined to keep the Germans rigidly to their contract. Mr. T. Roles, the City Electrical Engineer, was actually in London on his way to Germany when war broke out. The substituted contract was secured by the British Westinghouse Co., who, he thought, had carried it out very successfully. The cost of the scheme had been about £80,000. Reference was also made to two interesting additions to the connections. One is for 1,000 kw. per 24 hours all the year round for electric furnace work, whilst the Dumb Mills, in which over 25,000 spindles are to be installed, are to be run electrically off the Corporation mains.

Londonderry: Municipal Wiring.—The Corporation has asked the Belfast Corporation to adopt a resolution petitioning the Government to bring in a Bill authorising municipalities to undertake the electric wiring of premises. The Belfast Electricity Committee, however, do not propose to take any action in the matter. Why this matter should be raised seriously at the present moment is not quite clear. Obviously action either by the Government or the I.M.E.A. is impossible.

Oldham: Supply from Trolley Wires.—The ordinary supply mains in the Hollins district being already fully loaded, the Tramways Committee has agreed to supply a new power user in that district from the trolley wires.

South Africa: Shortage of Electrical Accessories.—The Natal Mercury reports that there is a notable local shortage in Johannesburg of high candle-power lamps, flexible wire, and electro-medical apparatus. It is also stated that half-watt lamps are unobtainable.

Wolverhampton: Loan Refused.—The L.G.B. has informed the Corporation that it is not prepared to sanction a loan of £5,000 to defray expenditure on ordinary extensions of mains. A loan, however, has been granted for giving a supply to certain firms engaged on war work.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Adelaide Electric Supply Co.—A resolution has been passed authorising an increase in the capital by a further 50,000 £5 shares.

Holophane.—An application will come before Mr. Justice Astbury on Saturday for the reduction of the capital of this Company from £200,000 to £105,000.

South Metropolitan Electric Light & Power Co.—A proposal has been put before the debenture holders to vary the trust deeds as regards the amount to be set aside to reserve or depreciation. At present the Company is bound to set aside a sum equal to 2½ per cent. of its share and loan capital, but it is suggested that this should be reduced to 1½ per cent. under certain conditions. The object, it is stated, is to enable a dividend to be declared on the ordinary shares at an early date. No dividend on these shares has been distributed since 1908, although the amount available last year would have enabled a dividend to be paid if some such variation as that now proposed could be offered. According to the *Financial Times* the debenture holders are objecting, and the requisite three-fourths majority in favour was not obtained at a meeting of the debenture holders last week. It was stated that the trustees hold sufficient proxies to prevent the scheme being carried if a poll is demanded.

The Institution.—The opening meeting of the session of the Institution of Electrical Engineers has again been postponed. Mr. C. P. Sparks will deliver his Presidential Address on Thursday, Nov. 18th.

The National Illumination Committee.—A meeting of the National Illumination Committee of Great Britain was held at the Institution of Electrical Engineers on Oct. 20th, 1915, when it was reported that Mr. Jacques Abady had been nominated by the Institution of Gas Engineers as a member of the Committee to fill the vacancy caused by the death of Mr. Edward Allen. The Committee elected Mr. W. Duddell, of London, to be chairman in succession to the late Mr. Allen, and Mr. John Bond, of Southport, to succeed Mr. Duddell as one of the vice-chairmen. Reports on observations carried out, at the instance of the Committee, at a number of technical laboratories, on the height to which the flame of the Hefner amyl acetate lamp should be raised to afford a light on one International or English standard candle, were discussed, and their further consideration was postponed. A report by Dr. E. Ott, of Zurich, on researches carried out in Switzerland on the effect of atmospheric pressure, humidity and vitiation on the light afforded by the Hefner standard lamp was considered, and it was decided to prepare a translation of the report for communication to the English technical press.

Westinghouse Lantern Slides.—The British Westinghouse Co. (Trafford Park, Manchester), call attention to the large and varied selection of lantern slides which they have. These are freely loaned to responsible persons, and the lecture season having now commenced, some of our readers will probably welcome this offer by the Company.

A Shooting Contest.—A friendly match between teams representing the British Electric Transformer Co. and the Ediswan Rifle Club, which took place by arrangement with the former club at Hayes, Middlesex, last Saturday afternoon, resulted in a win for the British Electric Transformer Co. by 554 to 541 points. The visitors were kindly entertained to tea after the match.

Centralisation of Supply in Scotland.—In his Presidential Address to the Institution of Engineers and Shipbuilders in Scotland on Tuesday last week, Mr. W. W. Lackie, the Glasgow City Electrical Engineer, made some interesting remarks with regard to the size of power stations and the possibility of dividing Scotland into areas for electric supply purposes. At present there are thirty-one electricity supply undertakings in Scotland, with a total capacity of about 120,000 kw. It would be possible, however, said Mr. Lackie, to divide Scotland into three areas for the purpose of electric supply, of which the lowlands south of the River Tay would represent two areas, and the whole of Scotland to the north of the Tay the third. Taking Falkirk as the boundary between the two first-named areas, the demand in the western area amounted to 80,000 kw., and that in the eastern area to 25,000 kw. From this, he said, three moderate-sized stations would meet the entire demands of Scotland.

SUMMARY

MR. S. E. FEDDEN, General Manager and Engineer of the Sheffield Electricity Supply Department, recently took the unprecedented course of placing orders for £120,000 worth of machinery upon his own responsibility (p. 452).

A REPLY is given to Mr. Nichol Moore's letter last week on the effect of enlistment upon electricity works (p. 452).

HEYWOOD (Lancs.) now uses bulk supply from Bury for its extensions. Overhead transmission at 6,300 volts is used, and an interesting feature of the plant is the automatic battery regulation (p. 453).

THE prospects for electrical trade with China are referred to (p. 453).

OUR Questions and Answers Columns deal with an adjustable resistance for occasional testing purposes (p. 455).

AMONG the subjects of specifications published by the Patent Office last Thursday are controllers, telephone transmission switches and wiring accessories. A wireless telegraph patent is opposed, and the grant of a microphone patent has been refused. Patents for a telegraph perforator and an insulating compound for core plates expire this week after a full life (p. 456).

WE outline proposals by the Electrical Contractors' Association for dealing with the position which has arisen in connection with the Board of Trade objections to the Guaranteed Wiring Scheme (p. 456).

A DESCRIPTION of a picture-lighting fitting is given (p. 457).

THE Minister of Munitions points out that employees of electrical undertakings are essential to the proper supply of munitions of war, and should remain at their posts (p. 457).

NEW generating plant is required at Luton (£25,650); turbo-alternator and induced draught plant at Manchester; services and meters at Belfast; boiler plant at West Hartlepool; cable and switchgear at Hackney (p. 458).

AN alteration is to be made in the arrangements between the St. Marylebone Electricity Department and the local wiring contractors (p. 458).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDANT.

Drills: 6.25 to 7.25; 7.25 to 8.25.

(To-day) Thurs., Nov. 11th: Sec. III., technical. Sec. I., shooting or working party.

Fri., Nov. 12th: Sec. IV., technical. Sec. II., squad or working party.

Mon., Nov. 15th: Sections I and II., technical. Sections III. and IV., squad or working party. Recruits and signalling section.

Tues., Nov. 16th: School of Arms with Architects Corps, 6.0 to 8.0 p.m.

Thurs., Nov. 18th: Sections III. and IV., signalling section, shooting.

Fri., Nov. 19th: Sections III. and IV., technical. Sections I. and II., squad or working party. Signalling section and recruits.

Sat., Nov. 20th: Uniform parade, 3 p.m.

Sections for technical parade at Headquarters, London Electrical Engineers, 46 Regency Street.

Sections for shooting parade at the miniature ranges.

Unless otherwise ordered, all parades at Chester House.

Until further orders, Sections I. and II. will parade on Mondays for technical, and on Fridays for squad drill, and Sections III. and IV. will parade on Mondays for squad drill and Fridays for technical, but Sections I. and II., and III. and IV. will alternate weekly for shooting on Thursdays.

Signalling Section will shoot on the same days as Sections I. and II.

Arrangements for the Week.—(To-day) Thursday, Nov. 11th. Yorkshire Section, I.E.E. Hotel Metropole, Leeds. Chairman's Address by H. H. Wright. Smoking concert, 7 p.m.

Friday, Nov. 12th. Physical Society. Imperial College of Science, S. Kensington. "The Effect of Electric Oscillations on the Magnetic Properties of Iron, investigated by the Campograph," by Prof. J. A. Fleming. 5 p.m.

Tuesday, Nov. 16th. Manchester Section I.E.E. Engineers' Club, Albert Square. Chairman's Address, by B. Welbourn. 7.30 p.m.

Thursday, Nov. 18th. Institution of Electrical Engineers. Presidential Address by C. P. Sparks. The premiums for last session will be presented. 8 p.m.

Excess Profits Tax.—We understand that the Chancellor of the Exchequer recently received a deputation representing an important and influential group of London and provincial electric supply undertakings with regard to the position of companies existing under statutory limitations, in the matter of taxation of excess profits. The Chancellor stated in reply to a question in the House of Commons a short time ago that the question of the adequacy of the 6 per cent. rate of return in respect of such companies would be a matter for consideration by the Board of Referees under Clause 38 of the Finance Bill.

£120,000 PLANT ORDERED IN ADVANCE OF LIGHTING COMMITTEE'S SANCTION

An example of how to do things, notwithstanding the hide-bound regulations under which municipalities have to work at the present moment, particularly in the matter of capital expenditure, has been provided at Sheffield. We pointed out on p. 391 of our issue of September 23rd that a scheme of extensions estimated to cost £100,000 had been prepared, and that the Ministry of Munitions had given its consent, together with its undertaking to make some arrangements whereby, at the close of the war, the plant should, if necessary, be taken off the hands of the Corporation. Meanwhile the urgency of the demands upon the undertaking had reached such a point that Mr. S. E. Fedden, General Manager and Engineer of the Corporation electricity undertaking, took a course which few other central station engineers would have risked: he just ordered on his own responsibility plant costing £120,000.

Those who know Mr. Fedden best realise full well that this is precisely what he would do when faced by a situation of this sort, and the fact that his Electricity Committee has absolved him in the matter stamps the members as progressive as their engineer. The record of the Sheffield electricity undertaking, particularly in the direction of power supply, is sufficient commentary upon the efficiency of its management, and although Mr. Fedden's action will probably make some of our more old-fashioned public officials and councillors rub their eyes, nevertheless those central station engineers who regard the necessities of their undertakings as of more importance than the strict adherence to regulations, which even in times of peace are a source of great irritation to practical men, will admire Mr. Fedden for giving them a lead which may come in useful to themselves some time or other. In addition to the £120,000 mentioned, the Emergency Committee of the Electricity Committee has sanctioned, without waiting for the full Committee's approval, various other items of expenditure, aggregating some £10,000, particularly in increasing the coal-handling plant and storage at Neepsend.

Locally, of course, there has been much satisfaction at what has been done, although some regret is expressed at the policy of the Department in continuing in force pre-war charges notwithstanding the enhanced prices for coal and labour, and also the fact that many of the works which are being supplied at very low rates for power are making considerable war profits. This, however, is more or less a domestic matter with which we are not concerned at the moment. We will content ourselves with congratulating Mr. Fedden upon his businesslike grip of a situation which, had it been allowed to run the normal course of officialism, might have resulted in manufacturers engaged on Government work being seriously handicapped through shortage of power supply.

CORRESPONDENCE

THE EFFECT OF ENLISTMENT AND MUNITION WORKING ON ELECTRICAL UNDERTAKINGS.

To the Editor of ELECTRICAL ENGINEERING.

SIR.—Mr. Nichols Moore's letter in your current issue is very welcome. He does not agree with all the ideas I put forward, and that is why I am glad to see his contribution.

Mr. Moore has dealt with his problems in accordance with his local circumstances: we have done the same, and I can assure him that our problems in the matter are much stiffer than is the case at Newport. One large town adjoins another in our part of the country, and there are literally square miles of munition works, all crying for men..

When a man can make over £2 a week more than we could give him the opportunity to make, then a six weeks' holiday with a sure job at the end thereof has its attractions.

We did not *make* work in order to give our men overtime, and if Mr. Moore refers to the article he will see that it is distinctly stated that they were put on to jobs which had been side-tracked owing to our usual complement of men having been depleted by enlistment. These are jobs which would have had to be tackled sooner or later, and one such job is already saving us a fair amount in the handling of our coal. We are paying more for the work, but even then it is cheaper than letting our men, who know every nook and cranny of the place, go. They realised that they would get no more advances, and naturally were inclined to take up the idea of playing for six weeks. The overtime gives them some extra money, which, though not what they might earn, keeps them with us, as they feel that the plant is doing something for them, and they have no need to turn out to another shop. The junior assistants have been prevented

from leaving simply because other chief engineers besides Mr. Moore have adopted the plan of not taking them without their present chief's consent. I have been repeating the "patting on the back" process every day since the article was written, and, in fact, have more reason to be thankful for our policy almost every day that passes.

When the policy was adopted it was done after having considered *all conditions* under which we were then working, and had there been financial danger and no reserve fund, things might have been a good deal different; but again circumstances alter cases, and, moreover, the plant we retained is not of the old crock variety, but is good plant having a very decent economy and being extremely reliable. Many important works depend on us for their power, and these older plants have helped us out of many a tight corner.

The connection between munition making, electricity works, and the international situation is so plain that I am surprised at Mr. Moore stating he is unable to see the connection. This attitude is, unhappily, characteristically British, and has accounted for our failure to meet the Hun in commerce to a greater extent than is generally realised. Unless we alter our tactics we shall suffer again after the war.

I do not know how much extra plant Mr. Moore is installing, and will be compelled to instal in order to cope with the munition works load, but I do know that we are in for heavy capital commitments on that account.

After the war, when the munition stocks are properly replenished, there will be a very bad slump in trade, unless steps are taken to prevent it. This slump in trade will throw thousands of machine tools idle, and, in consequence, the factories will not require much power for a considerable time. We shall then be in the position of having large plants in our stations which will hardly run sufficiently to earn their upkeep and maintenance charges, let alone any return on the investment.

To prevent such a calamity international measures are necessary. The measures which in my opinion might suffice, and the reasons which make them necessary—well, are they not written in the original article which appeared in October, even on the seventh day of that month?

There was another good reason for my dissertation on international questions. The Editor asked me to state my opinion on the probable situation after the war, and the manner in which that situation would affect electricity works.

I conclude with thanks to Mr. Moore for his letter.

Yours faithfully,

THE WRITER OF THE ARTICLE.

Nov. 6th, 1915.

BRITISH ELECTRICAL TRADE WITH RUSSIA.

To the Editor of ELECTRICAL ENGINEERING.

SIR.—We have the honour to ask you to note that this Company, who are concessionnaires of the electric lighting stations in Pawlowsk, Uman, Kameuetz, and Podolsk, and of tramways in Elizabethgrad and Uman, have opened a branch for the sale of electrical machines and apparatus, insulating materials, steam and naphtha engines and water-turbines, and desire to enter into relations with first-class factories in your country producing these goods with the view of becoming their agents in Russia.

At the same time we have the honour of informing you that as our Company belongs to the Russian and French Bank, we are able to offer for all our engagements the complete guarantee of this Bank.

We remain, yours faithfully,

RUSSIAN SOCIETY FOR ELECTRICAL ENTERPRISES, LTD.
Petrograd, 5 Marsowo Polje, Oct. 25th, 1915.

Thirty Volts would not have Killed Him.—What the coroner called a stupid device caused the death of an assistant in a restaurant at Neath (S. Wales) last week. The proprietor of the restaurant, an Italian, had connected a brass rail running along his counter with the supply main, and at the same time had had a metal plate let into the floor along the front of the counter. Obviously anyone standing on the plate and touching the hand-rail would receive a shock, and it so happened that one of his assistants did this, and being, according to the medical evidence, in a low state of health, and suffering from heart disease, the shock was fatal. The restaurant keeper explained at the inquest that he had put in the device in order to prevent boys from stealing off the counter. An electrical engineer who gave evidence, stated that the supply voltage was 220-volts, but 30 volts was the maximum he had been able to obtain by a test at the spot where the deceased man received his fatal shock. The coroner censured the proprietor, and the jury added a rider to their verdict that the Corporation should have any similar device, if such exists in the town, done away with.

BULK SUPPLY EXTENSIONS AT HEYWOOD

HEYWOOD, a Lancashire town of 27,000 inhabitants, about $3\frac{1}{2}$ miles from Bury, has 617 kw. of lamp connections and 400 kw. of motor connections, and a load factor

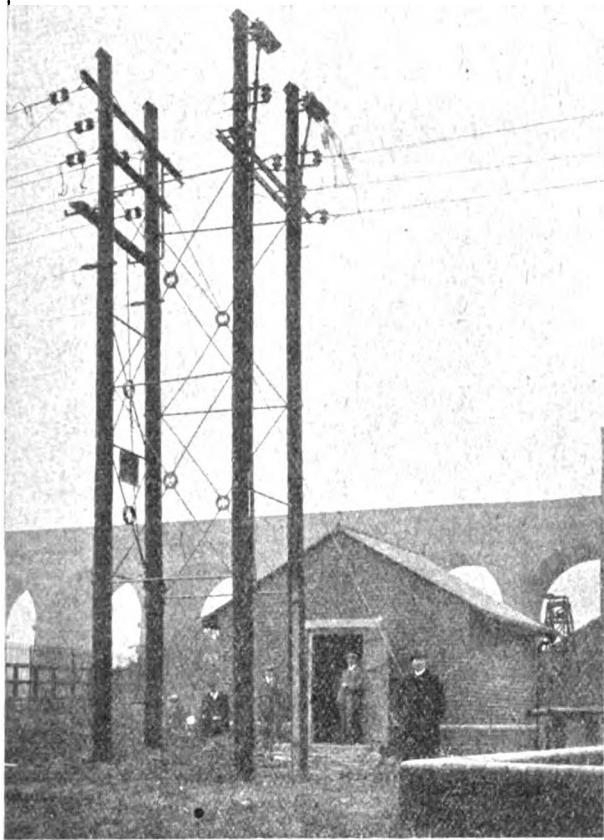

FIG. 1.—TERMINAL POLES AND METERING STATION.

of 22·6 per cent. Its costs per unit sold last year, including all charges except interest and sinking fund, were 1·07d. per

bulk supply from Bury for all future extensions, and the first instalment of these was formally opened on October 30th.

The transmission line from Bury to Heywood is overhead except for two short lengths of underground cable at each end. A view of the metering station and terminal pole-line arrangement is shown in Fig. 1. The E.H.T. cables would, in the ordinary course, have been in duplicate, but at the request of the Local Government Board only one line has been erected at present, and a second one will be put up later. Current is received at 6,300 volts, three-phase, 50 cycles, and converted to D.C. by means of a static transformer and rotary converter, the capacity of the converting plant being 600 kw. Fig. 2 is a complete view of the new plant, and Fig. 3 shows the Westinghouse E.H.T. switchgear to a larger scale. The rotary converter is also Westinghouse, is fitted with a booster, and has inter and compensating poles and the Westinghouse patent self-synchronising method of starting. A feature of this machine is that it has only two bearings.

A Tudor battery with a capacity of 840 ampere-hours at the 10-hour discharge rate (220 amperes for three hours, 280 for two hours, and 440 for one hour) has been put in, and an interesting Bertram Thomas automatic regulating switch is used in conjunction with it, which, besides regulating the voltage automatically, has the additional advantage of saving long leads for regulating cells. A pair of these automatic switches are used, one for the positive and one for the negative cells, on either side of the three-wire system.

Each switch consists of two parts: a regulating switch carrying the main current, and a voltage regulator or governor controlling the operation of the regulating switch. In the arrangement at Heywood the battery contacts on the former are arranged in a circle, and there are two moving contact arms, one for charge and one for discharge, moving over the same cell contacts, but making connection with two independent ring contacts. The discharging arm only is made for automatic operation, and the charging contact arm is moved by hand. The discharging arm is moved by the operation of two solenoids, one for cutting in cells and the other for cutting out. The solenoid cores engage with the contact arm through a system of pawls and toothed wheels, so constructed that one stroke of the solenoid carries the contact arm accurately from the centre of one contact to the centre of the next, and the pawls and wheels are so shaped and locked that there is no possibility of overshooting. At the top of the stroke of the solenoid the supply of current to it is automatically interrupted on carbon contacts

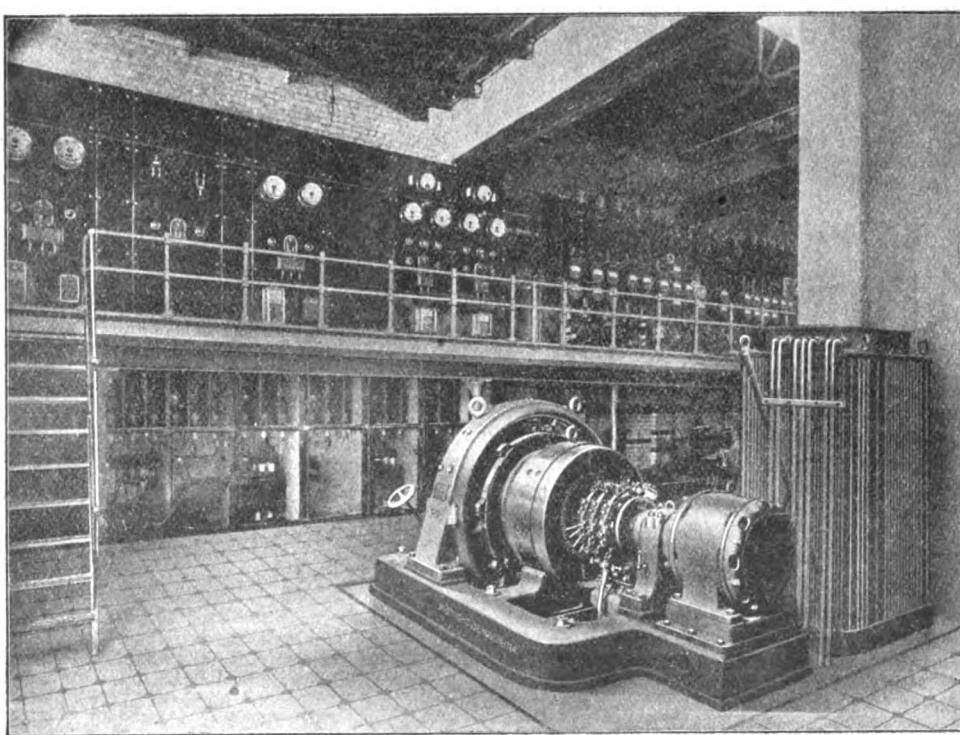

FIG. 2.—THE NEW PLANT.

unit. On the advice of the Borough Electrical Engineer and Tramways Manager, Mr. R. B. Leach, it was decided to take

in a magnetic field, and this contact is re-established under the control of a dashpot with variable time element, enabling the

interval between the strokes to be regulated as desired. Thus the controlling governor is called upon to make contact only, and the sparking at the governor contact points is practically nil.

The main regulating switch is also provided with limit switches which come into operation at each end of the range of the contact arm, and prevent the contact arm from being driven past the last contact. The main contact arms are each provided with a pilot brush and resistance for preventing short circuit of adjacent cells at the moment of change.

The governor is a moving arm making contact either at the top or bottom of its range, and controlled by a powerful solenoid wound with fine wire, and connected across the bus-bars. Normally the contact-arm floats evenly between the two contact blocks.

In order to ensure the supply of current to the operating solenoid of the regulating switch over such a period as is required to complete the stroke, "accentuating coils," on much the same principle as retaining coils of telephone relays, are fitted to the governor in such a way that immediately the contact points touch and current passes, a small auxiliary magnet is energised which attracts a flexible iron armature on the moving contact arm, and thereby exerts a pressure between the contact faces until such time as the current is cut off at the contacts on the main regulating switch.

ELECTRICAL TRADE IN CHINA

M R. W. G. L. RIDDELL, President of the Birmingham & District Electric Club, has returned from a 12-months' tour in China, and a dinner was given him last week by the members. In our last issue, p. 434, we published an interview with Mr. T. W. Ainscough, the Board of Trade Special Commissioner, who has also just returned from China, and Mr. Riddle's remarks on the question of trade in China formed a useful supplement to the information given in our article last week. After a reference to the considerable success of the Shanghai electrical undertaking, where current is being supplied for power purposes at as low as £2 10s. per kw. per annum, plus 4d. per unit, Mr. Riddle drew attention to the keenness which the Chinese are showing in the possibilities of electric driving. One reason, he thought, for this was the absence of any form of administrative control which tended to discourage enterprise. There was in China, he said, no Board of Trade or Local Government Board to perform this function. Nevertheless, he thought the electric supply industry in China would benefit by regulations to ensure a reasonable degree of safety. Any

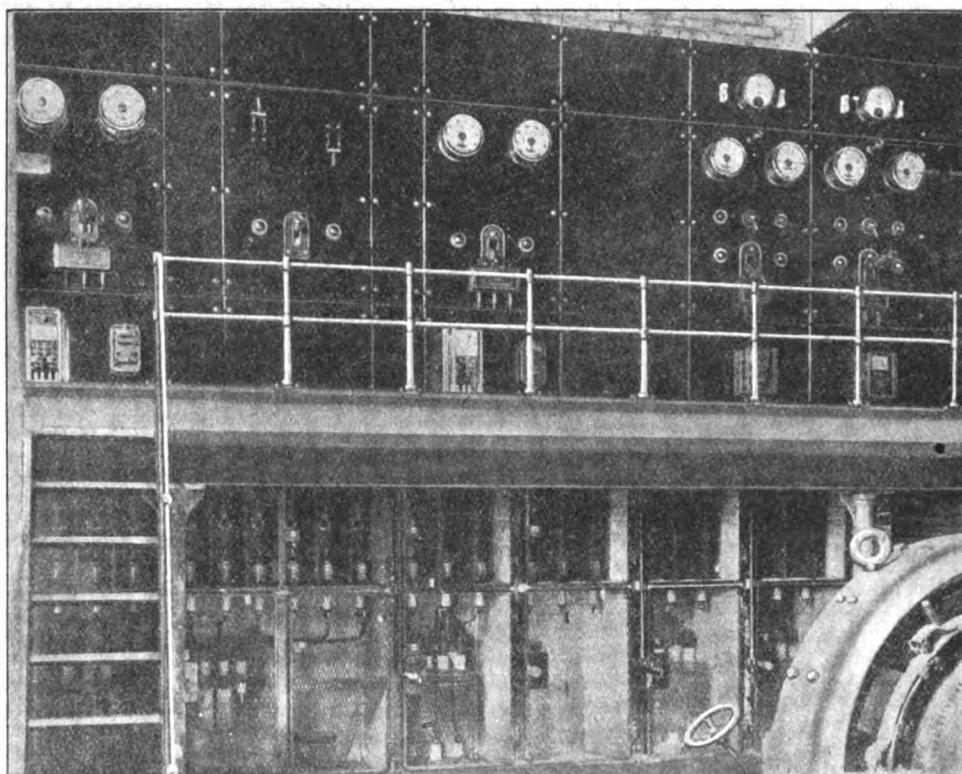

FIG. 3.—E.H.T. SWITCHBOARD.

An electrically operated indicator completes the equipment. This is fixed on the switchboard, and shows the number of cells in circuit at any given moment.

Special change-over switches have also been fitted in circuit with the battery boosters. In the event of the breaker of a booster motor tripping, the booster is automatically cut out, leaving the battery floating on the bus-bars; and if the discharge becomes so great that the boosters are overloaded, the switches clear the booster armatures, again leaving the battery floating.

We are indebted to Mr. Leach for much of the information contained in this article and the loan of the blocks, and to Mr. Bertram Thomas for details of his ingenious automatic switchgear.

Municipal Wiring.—The report of the Ironmongers' Federated Association for the year just completed, in calling attention to municipal trading, states that the Electrical Committee of the Glasgow Corporation has made as fair and equitable arrangements with the trades affected as could be expected. We gave particulars of the arrangements between the Glasgow Corporation and the Glasgow electrical contractors in our issue for March 25th, p. 128. At the same time the report adds that members should closely watch the encroachment on their trade by municipalities and urban district councils and advise headquarters of any new departure in this direction which comes to their notice.

review of the position of trade in China seems to be out of place without some reference to the favourable terms offered by Continental firms, and Mr. Riddle mentioned the case of a 10,000 spindle electrically-driven cotton mill which was built and equipped without any expenditure by the owners, the arrangements being that its cost was to be met by the surplus revenue after payment of a minimum dividend. Since the outbreak of war neither Britain nor Germany had been able to take contracts, but he believed that Germany would be in the field with renewed vigour when the war was over. At the present time America and Japan were securing the bulk of the trade.

Killed in Action.—The County of London Electric Supply Company, which has already lost a number of its employees in the war, has sustained further losses of this character. Private G. W. R. Peek, of the 6th Battalion, Duke of Cornwall's Light Infantry, who was previously a motor inspector in the Mains Department, was wounded in France on October 9th in the attack near Hulluch, and subsequently died of the wounds on October 12th. Corp. Sydney A. Wood, of the Machine Gun Section, "B" Company, Norfolk Regiment, who was also previously employed in the Mains Department, was killed in action on October 9th near La Bassée, and another employee in the same department, Private E. Gordon Morley, of the Queen's Westminsters, was killed in action on October 12th.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,468.

I have a D.C. motor rated at 20 h.p., 950 r.p.m., which drives some line shafting for machine tools. It is a 220-volt, 4-pole, shunt machine, with lap-wound armature, and has good commutation. I wish to increase the normal speed to 1,100 r.p.m. for special work during the war, and then to reduce it again to its normal value. What is the most economical way of doing this?

(Replies must be received not later than first post,
Thursday, Nov. 18th.)

ANSWERS TO No. 1,468.

It is desired to make up an adjustable resistance for occasional testing purposes in a small works, to give a voltage drop of 100 with a current of 5 amps. Describe a cheap method of doing this; state the material used, and the approximate cost of the resistance.

The first award (10s.) is given to "L. R." for the following reply:

The best resistance to use depends to a large extent on the exact purposes for which it is required, whether it is to be constant over a certain range of temperature or not, its capacity for variation, its permissible temperature rise, and so on.

The cheapest depends to some degree on what materials are available. A suitable resistance could be made from plain iron wire, from any of the modern high-resistance materials, or a liquid resistance could be schemed. Probably the middle class of the three will be the most satisfactory, but for accurate work some of the more expensive forms, such as manganin or platinoid, may be necessary. In these circumstances I have calculated the following table covering most of the usual resistance materials, basing it on a wire to carry 5 amperes with a drop of 100 volts.

In the case of eureka, platinoid, and manganin I have allowed for a small temperature rise only—that is, for the wire to be heated to blood-heat.

In the case of the other materials I have allowed for a temperature rise of 100° C. This should be permissible for ordinary resistances, but it may be undesirable to exceed this because of certain disadvantages, including the fact that fuses in the circuit may have to be altered because of the possible high current flow at starting.

| Material. | Size S.W.G. | Weight in lbs. | Length in vds. | Price per lb. | Cost. |
|---------------|----------------|-------------------|-------------------|------------------|-------|
| Eureka | ... 14 | 1·12 | 150 | 3/- | 3/4 |
| Manganin | ... 16 | 3·95 | 106 | 4/8 | 18/4 |
| Platinoid | ... 16 | 4·15 | 110 | 3/- | 12/6 |
| Chronic | ... 15 | 2·82 | 59 | 6/- | 17/- |
| Ferrozoid | ... 14 | 5 | 50 | 2/- | 10/- |
| Ferry | ... 17 | 2·12 | 73 | 2/5 | 5/2 |
| Tarnac | ... 18 | 1·32 | 62 | 3/1 | 4/1 |
| German silver | ... 17 | 2·5 | 87 | 2/- | 5/- |
| Zodiac | ... 17 | 1·68 | 58 | 2/- | 3/4 |
| Cupro I. | ... 18 | 2·04 | 97 | 1/9 | 3/7 |
| Cupro II. | ... 19 | 1·28 | 87 | 1/8 | 2/2 |
| Beacon | ... 16 | 1·53 | 47 | 3/8 | 5/7 |

The cheapest of these for the present case is therefore Cupro No. II., but it does not follow that the exact sizes

mentioned are necessarily in stock. Thus in that case the present list gives the largest size as No. 20 instead of No. 19. The difference is practically nil, as it only means that the wire will work at a temperature a few degrees above 100° C. On the other hand, large changes of temperature make a considerable difference in the cost. Take, for instance, Ferry. If this can be worked at 200° C., a No. 19 wire will suffice, the weight required being 0·56 lb., which at 2s. 5d. per lb. costs 1s. 4d. On the other hand, at 800° C. a No. 21 wire will suffice, 0·22 lb. at 2s. 6d. being required, costing 7d.

For Cupro No. II. at 200° C. 0·28 lb. of No. 22 at 1s. 8d. (cost 6d.) is necessary, and for 800° C. 0·08 lb. of No. 25 at 1s. 11d. (cost 2d.).

If a plain iron wire be used, about No. 17 would be required, and of this 5·7 lb. at 1s. a lb. (5s. 8d.) would be necessary.

In the case of a liquid resistance, a vessel about 12 in. in diameter and 4 ft. high should be provided, and the liquid composed of a solution of soda in water, 1lb. to $\frac{1}{2}$ lb. of soda per gallon being sufficient. The cost of this liquid is clearly nominal.

The way the resistance is mounted depends on what materials are handy. Thus an old motor-starter plate could be connected up to sections for cutting out the resistance step by step, and if this sub-division be not fine enough, a length of wire approximately equal to the length of one of the sections should be connected at one end to the starter arm or end stop, with a contact finger movable along it.

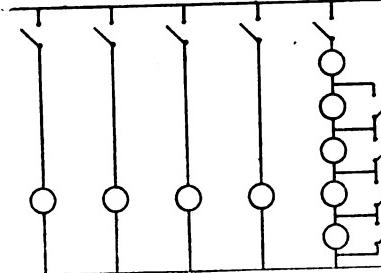

Again, in the case of the shorter lengths of wire, the wire can be wound on a rotating drum with fixed contact pointer, but it may be pointed out "Beacon" should not be wound on asbestos.

For a liquid resistance, if a vertical jar be used, the top electrode should be counterbalanced; but if the resistance be made in the form of a trough, clearly this is unnecessary.

The second award (5s.) is made to "J. G. M." for the following reply:

A simple and inexpensive resistance can be made with carbon filament lamps. An ordinary carbon lamp absorbs roughly four watts per c.p., so that a 25-c.p. 100-volt lamp will pass approximately one ampere. If, therefore, five of these lamps are connected in parallel and each controlled by a switch, a very efficient rheostat is obtained which will drop 100 volts at currents of one to five amperes in steps of one ampere.

If finer regulation is required, lamps may be coupled in series as well as parallel. The accompanying diagram shows such an arrangement, representing four lamps in parallel

and five in series. Assuming all these to be 25-c.p. lamps, then the five in series will absorb 100 volts and pass 0·2 amp.; and if these are short-circuited one at a time until only one remains, the current increase 0·2 amp. per step to 1 amp. Therefore it is obvious that with this simple arrangement the current can be varied between 0 and 5 amps. in steps of 0·2 amps., and is equivalent to a 25-way regulator.

If still finer regulation is required, more lamps may be put in series or lamps of smaller candle-power used; for instance, an 8-c.p. lamp takes approximately 0·3 amp., and three in series will give 0·1 ampere. On the other hand, if fine regulation is not required, lamps of higher candle-power may obviously be used.

The lamps are mounted in batten-type holders screwed to a wood base, the controlling switches being cheap tumblers. These fittings are very cheap, and the price of a complete rheostat, not counting the labour, may be taken as two shillings to half-a-crown per lamp. The number of lamps required will, of course, depend on requirements of the particular case.

Provisional Orders.—The Board of Trade give notice to parties contemplating the promotion of Provisional Orders in respect of electric lighting, gas and water, piers and harbours, and tramways, that for the duration of the war they will not be prepared to entertain such applications, except in cases in which they are satisfied that extreme urgency exists.

"ELECTRICAL · ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 4th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

14,146/14. Controllers. F. N. PICKETT. Face-plate starters and controllers, in which sparking at the studs is prevented by an auxiliary brush connecting the stud under the main brush to the next stud through a contactor switch, which opens and puts the resistance step in circuit after the contact has been made. (One figure.)

18,511/14. Telephony. G. MUSSO. A system of transmission of telephone impulses over lines of high capacity, wherein the main line is provided at each end with a local circuit containing a battery, transmitter, and inductance, whereby the battery maintains a charge on the line, upon which are superposed secondary and tertiary waves induced in the inductance for respectively neutralising and overcoming the capacity and resistance. (Two figures.)

20,896/14. Switches. H. C. HEATH. A tumbler switch with an automatic free handle device, consisting of a releasable mechanism between the handle and the bridging member, provided with means to release the latter from the point at which circuit is completed to the full "on" position, when an abnormal condition exists in the circuit. (Four figures.)

23,050/14. Wiring. F. W. SUTER and BAXTER & CAUNTER, LTD. Fittings for a looping-in system of wiring, in which the two wires forming the "loop," instead of being twisted together as is usual, are brought to separate contact blocks normally connected by a bridge piece removable for testing purposes. (Ten figures.)

2,636/15. Electric Ordnance. T. C. TULLIOCH. An electric gun or mine-thrower in which the projectile is propelled by the movement of an independent core accelerated in the barrel, but afterwards retarded and prevented from leaving it, by the action of a solenoid. (One figure.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

DYNAMOS, MOTORS, AND TRANSFORMERS: BACK [Brush-holders] 459/15.

Heating and Cooking: REIMERS & KIEFER [Electric pressing irons] 21,184/14.

Switchgear, Fuses, and Fittings: MILLER [Switches] 21,593/14; LEITNER [Switches] 21,993/14; IGRANIC ELECTRIC CO. (Cutler Hammer Mnf. Co.) [Controllers] 5,104/14; R. BOSCH [Switches] 8,047/14.

Telephony and Telegraphy: WESTERN ELECTRIC CO. (W.E. Co., U.S.A.) [Ionisation amplifiers] 1,694/15.

THE E.C.A. GUARANTEED WIRING SCHEME

FURTHER progress has now been made by the Electrical Contractors' Association in its endeavour to get over the objections of the Board of Trade to the Guaranteed Wiring Scheme which we dealt with on page 405 of our issue of October 7th. We subsequently mentioned that at a special meeting held at Leicester a Committee was appointed to deal with the position. The November issue of *The Electrical Contractor* now states that a general line of action has been schemed out which will overcome the objections to the guaranteed scheme, and at the same time allow the general business of the Association to be conducted with even greater vigour than has been possible in the past.

It has been decided to run three organisations. The first will be the Electrical Contractors' Association, in much the same state as that which has prevailed up to the present. In the second place, it is proposed to form a limited trading concern possessing very wide powers and capable of carrying on all the activities of the Association, which are at present under suspicion as being outside the scope of the original charter. This limited trading concern will be able to put the guarantee scheme into immediate operation and support all the financial arrangements in connection with it. It will also

Traction: DELMEZ [Rail grinder] 29,965/14; MASCHINENFABRIK OERLIKON [Engine starter] 180/15.

Miscellaneous: BRIT. INS. & HELSBY CABLES, LTD. [Condenser circuits] 21,086/14; MELLERSH-JACKSON (*Commonwealth Electric Tool Co.*) [Electrically-actuated tools] 21,145/14, 6,302, 6,364, and 6,738/15; BLAKE [X-ray bullet localiser] 23,653/14; TEDESCHI and Rossi [Relays] 8,903/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

DYNAMOS, &c.: LA COUR [Converter] 14,516/15.

TELEPHONY: BETHENOD [Wireless telegraphy] 14,500/15.

TRACTION: REIK [Electro-mechanical driving arrangements] 14,548/15.

Opposition to Grant of Patent

Opposition has been entered to a grant on the following specification:-

12,277/14. Wireless Telegraphy. A. F. SYKES. A system of transmission in which sparking at the key is avoided by controlling the current by periodically adding substances to a liquid jet forming part of the circuit, to diminish its conductivity.

The grant of a patent has been refused on the following application which had been opposed:-

9,637/14. Telephony. E. C. R. MARKS (*Electrical Experiment Co., U.S.A.*). A microphone in which a rigid diaphragm is held between pneumatic cushions.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:-

22,844/01. Telegraphy. J. GELL. An improved form of perforator for tapes for automatic transmitters.

22,990/01. Insulation. J. W. SANKEY. A special insulating compound, which can be sprayed or painted on to iron core plates, &c.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: H. BECK [Flame arc lamp] 16,294/03; S. C. MOUNT [Arc lamp] 15,346/08.

DYNAMOS, MOTORS, and TRANSFORMERS: H. H. LAKE (*Compagnie de l'Industrie Electrique*) [Device for preventing undue rise of potential difference between the frame and windings of machines in the Thury system] 16,190/03; A.E.G. [Single-phase motors] 16,529/07.

Incandescent Lamps: SIEMENS & HALSKE [Metal filaments] 11,603/08.

Storage Batteries: K. L. BERG [Battery plates] 15,952/04.

Switchgear, Fuses, and Fittings: A. P., G. C., and P. A. LUNDBERG [Switches] 16,574/07.

Miscellaneous: C. H. PRÖTT [Electric fan and air humidifier] 16,375/02; W. E. LAKE (*C. E. Sanford, U.S.A.*) [Electric clocks] 16,500/07; A. C. KING, P. HAMER, and J. KING [Electrical variable speed gear] 15,322/08.

carry on the present trading agreements of the Association, negotiate fresh trade agreements if necessary, buy goods in bulk, to act as a co-operative undertaking, and may even go so far as to manufacture any specific article. These are the suggested powers. In the third place, it is proposed to form a trade organisation which may or may not be registered as a trade union, the object of which will be to improve trade relations generally. It will seek to protect the manufacturer, contractor, and retailer against individuals or firms who seek to maintain unfair trading conditions, and the originators of it believe it will be in an admirable position for dealing with labour troubles and workmen's organisations in general. The membership of these three organisations will be as wide as possible, and there is nothing to prevent wholesalers, factors, and even central station engineers joining.

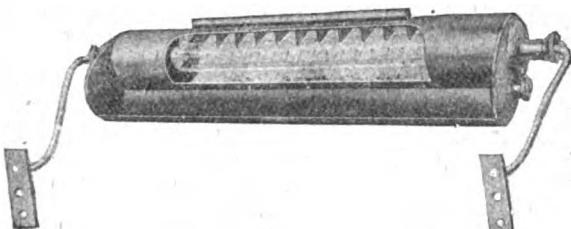

As far as arrangements go at present, it is intended that existing members of the Electrical Contractors' Association may become members of the other two organisations without extra fees or charges, although members of the other two bodies need not necessarily be members of the E.C.A. The idea also is that the capital for the trading company will be raised by the issue of shares, most of which will probably be taken up by the E.C.A. by way of investment of its reserve fund.

ELECTRICAL ENGINEERING

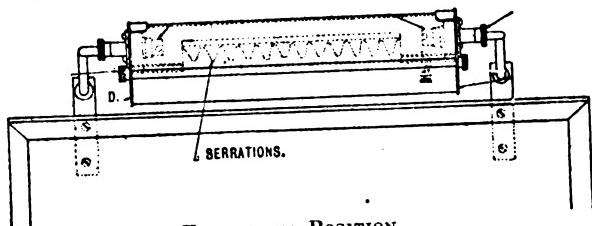

PICTURE LIGHTING

THE difficulties of lighting pictures adequately have been appreciated as one of the problems awaiting solution by the illuminating engineer, and efforts have been made to devise fittings which avoid the inconvenience of reflected light meeting the eye of the observer. The Edison & Swan United Electric

COMPLETE FITTING.

Light Co., Ltd. (Ponders End, Middlesex), have brought out the fitting of which we give two illustrations. It is claimed to be the only one capable of lighting a picture practically equal to or with a maximum illumination upon its prominent features, and is so arranged as to light only the picture. The stock length of the fitting is 18 in. over all, and takes a Tubelite lamp, but any length fitting can be made to order. The fitting con-

FITTING IN POSITION.

sists of a main tube with serrations free to turn upon supports, thus providing a means of adjustment. There is also a revolving screen to cut off the light at the bottom of the frame and from the wall below, whilst end-plates cut off the light from the sides. A notable installation of this type of fitting is in the choir stalls at Westminster Abbey. The wiring is perfectly protected, and the fixing quite simple.

LABOUR AT ELECTRICITY WORKS

THE Minister of Munitions announces that it has been brought to his notice that the working of many munition factories is being imperilled by the difficulties now being experienced by electric supply and gas undertakings providing them with power and light in retaining sufficient staff for their immediate needs. The Minister of Munitions points out that these undertakings are engaged upon work of vital importance, and the removal of their employees, even to munition work, may frequently have the effect of prejudicing the output of munitions of war. At the same time other employers are asked to assist the Ministry of Munitions by refraining from attracting labour from these essential undertakings.

The Institution and Enlistment.—Mr. C. P. Sparks, President of the Institution of Electrical Engineers, has sent a letter round to all members urging them to give immediate consideration to the employment of women in substitution of their clerical and similar staffs who are of military age. It is pointed out, however, that in the interests of recruiting it is highly important that the places of enlisted men should be kept open for them. This is an honourable rule, and so far as the Council is aware, a practically universal one in the branches of employment in question. No less desirable is it that the employment of substitutes for enlisted men should be known and declared to be temporary, and for the period of the war only. In these circumstances, the Council of the Institution impresses upon employers the importance of considering at once how their arrangements can best be remodelled as their present men are called up, and what number and class of women or other substitutes they will require.

Munitions Invention Department.—The Secretary of the Institution of Electrical Engineers has received a communication from the Ministry of Munitions asking for ideas, suggestions and inventions for appliances in connection with the prosecution of warfare on land. An Advisory Panel of scientific and other experts, upon which are a number of members of the Institution, is assisting in this work.

CATALOGUES, PAMPHLETS, &c., RECEIVED

ELECTRIC HEATING AND COOKING.—We recently referred in our "Local Notes" column to the efforts made by the Newcastle-on-Tyne Electric Supply Co. to popularise electric cooking and heating. The Company has sent us a copy of a well-got-up booklet dealing with the whole subject of electric cooking, heating, and hot-water supply. Illustrations are given of the apparatus, together with prices for purchase outright, as well as hire rates.

ELECTRIC FITTINGS AND GLASSWARE.—A very complete catalogue from Messrs. J. & W. B. Smith (15-23 Farringdon Road, London, E.C.) deals with a large range of electric fittings and glassware. This is a supplementary catalogue to be used in conjunction with the firm's general catalogue. Considerable advances in price are notified on the fittings.

ELECTRIC FIRES.—A 32-page book has been prepared by the Electrical Supplies Co. (53 Victoria Street, S.W.), in which electric fires, suitable for drawing-rooms, dining-rooms, bedrooms, &c., are fully illustrated and described. This will be gladly sent to all applicants. A two-page leaflet printed in colours, containing hints to potential users of electric fires is also useful advertising matter.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

ELECTRIC LAMPS.—Messrs. Krupka & Jacoby, Ltd. (39 Victoria Street, S.W.), have compiled a handy folder giving full particulars and prices of the lamps controlled by the Tungsten Lamp Association. Contractors will find this particularly useful, as it brings together in a small compass quite a lot of useful information.

MAZDA "POSTER" STAMPS.—Factors or contractors will find it to their advantage to make use of a new advertising medium placed at their disposal by the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), in the form of a set of six gummed and perforated poster stamps for use on letters, envelopes, or wherever else the ingenuity of the recipient may suggest. The "stamps," which measure about $3\frac{1}{2}$ by $1\frac{1}{2}$, are splendidly executed in colour, and make a vigorous appeal, whether taken individually or as a set. Any number of sets will be supplied gratis to *bond fide* applicants.

ARC LAMP CARBONS.—In view of the difficulties in obtaining arc lamp carbons at the present moment, those in need of supplies will be interested to know that the Electrical Supplies Co. (53 Victoria Street, S.W.), anticipating a recurrence to a great extent of the inconvenience encountered last season in obtaining adequate quantities, have made arrangements whereby they can quote for immediate delivery from stock in their London warehouse. A considerable advantage in price as compared with last season's figures is also offered. The Company inform us that they have a complete range of all sizes and types, and particularly 18 mm. by 12" cored, and 12 mm. by 12" solid for open type arc lamps; also 13 mm. by 12" solid suitable for enclosed arc lamps.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Athy (Ireland).—The Council invites tenders for lighting the town by electricity. The necessary permission will be granted for the erection of overhead lines or for the laying of underground mains. The public lighting will be fifty 50-c.p. lamps, for which the sum of £75 per annum for three years is offered. The present price of coal-gas to private consumers is 6s. 3d. per 1,000 cubic feet. Schemes should be sent to the Town Clerk not later than December 6th.

Belfast.—A loan of £3,443 is to be sought for services and meters during the next two years.

Greece.—Reporting upon the trade of the Piræus district for last year, the British Consul calls attention to the good market for electrical machinery, &c., and states that the reason for the success of Germany and Austria hitherto has been due to their sending very capable representatives with a practical knowledge of their duties, explaining to the buyers all they want to know about the machinery, and ready to agree to any alterations to meet local requirements. Representatives of British firms, he adds, are seldom seen in Greece.

London: Hackney.—Cable and switchgear are required in

connection with supply to a new factory which is being erected in the district on behalf of the Minister of Munitions. We refer at greater length to this under "Local Notes."

Luton.—A L.G.B. inquiry was held last week concerning a loan of £25,650 for new plant, made up as follows:— Generating plant, £14,450; sub-station and plant, £5,200; and H.T. and L.T. cables, £6,000.

Manchester.—Turbo-alternator and induced draught plant. Chief Electrical Engineer, Dickinson Street. November 17th.

Turton.—A scheme for supplying Harwood has been prepared by the Borough Electrical Engineer. The cost of erecting the necessary overhead cable is put at about £220.

West Bromwich.—Extensions estimated to cost £8,850 are to be carried out, by agreement with the Minister of Munitions.

West Hartlepool.—Additional boiler plant is required at the Seaton Carew power station.

Wigan.—The L.G.B. has sanctioned a loan of £6,700 for new boilers.

Wiring

Glamorgan.—Upper Loughor School. Clerk, County Hall, Cardiff. November 15th.

Glasgow.—Bernard Street School, Bridgeton. School Board Offices, 129 Bath Street.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Belfast.—Waggon repair shops, Adelaide Street. Great Northern Railway Co. (Ireland).

Bolton.—Extensions to Bradford and Hill Fold mills.

Devonport.—Children's Home.

Miscellaneous

Chatham.—Twelve months' supply of electric lamps. Borough Surveyor, Town Hall. November 24th.

Egypt.—The Alexandria Postmaster-General requires a twelve month's supply of electric lamps and fans. Superintendent of Stores, G.P.O., Alexandria. December 1st. Further particulars at 78 Basinghall Street, E.C.

Ireland.—Twelve months' supply of telegraph materials for the Sligo, Leitrim & Northern Counties Railway Co. Secretary, Enniskillen. December 1st.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

London.—Ozonair, Ltd., has recently received a further order from the London Electric Railway Co. for "Ozonair" plant. This is for the Leicester Square station of the Charing Cross, Euston & Hampstead Tube, and constitutes the seventeenth installation supplied to this Company.

Manchester.—The Electricity Committee have accepted the following tenders:—Bruce Peebles & Co., Ltd. (Edinburgh), for one 300-kw. motor converter for sub-station; Ferranti, Ltd. (Hollinwood), for two sets E.H.T. switchgear; M. Louis Prat (Paris) and Babcock & Wilcox, Ltd. (London), for induced draught plants.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £90 to £91 (last week, £89 to £90).

Agencies.—H.M. Consul-General in Paris, says the *Board of Trade Journal*, reports that an important engineering firm in that city desires to represent United Kingdom manufacturers of electrical supplies of all kinds. The firm in question points out that after the war there will be a great demand for electrical supplies for refitting the factories, &c., in those parts of France at present invaded. A unique opportunity will be afforded for United Kingdom manufacturers to secure a large part of the market formerly in German hands.

Competition.—The Electrical Supplies Co., as will be seen from our advertisement columns, is offering a prize of two guineas for the best suggestion of a name for their new premises.

APPOINTMENTS AND PERSONAL NOTES

Electricians are required at the South Eastern Hotel, Deal, and by the Lechlade Light & Power Co. (See advertisement on another page.)

Apprentices are required in the Keighley and Swindon Corporation Electricity Departments. Applications to the Borough Electrical Engineer in each case.

LOCAL NOTES

Bo'ness: *The National Co.'s Lease.*—The National Electric Construction Co., which leases the electricity works, proposes to make temporary extensions at an estimated cost of between £6,000 and £7,000. It is intended that payment for the work should stand over until after the war, when the Council should apply for borrowing powers, the Company receiving 6 per cent. on their capital outlay. Meanwhile, this will be charged on the profits of the undertaking.

Dover: *Garage Lighting.*—The Borough Electrical Engineer has been making an investigation of the number of units taken by garages in the town, and has found that the average is only 24 units per annum, but the capital charges in respect of each installation is 16s. 8d. a year, and his suggestion that a minimum of 10 units should be charged each quarter has been adopted. In the case of garages lighting through pre-payment meters, the minimum is to be 20 units per quarter.

London: *Hackney: New Factory.*—The Electricity Committee report that for some time past they have been in negotiation with Messrs. Dick, Kerr & Co., acting on behalf of the Minister of Munitions, in reference to a supply of electrical energy for a new factory now in course of erection in the district. The conditions agreed include the provision of the necessary additional switchgear and the laying of the requisite cable at the expense of Messrs. Dick, Kerr, who will repay the cost in monthly instalments as the work proceeds. The cables and switchgear are to remain the property of the Minister of Munitions, and when they cease to be used for their present purpose the Council is, before purchasing new cables and switchgear, required to purchase those now being installed from the Minister of Munitions at ruling prices, subject to deduction for the ascertained cost of recovery and unavoidable waste in adaptation. Supply is to be given at 6,000 volts, three-phase, 50 periods.

St. Marylebone: *Wiring Contracting.*—Since December, 1913, the Electricity Department has passed on inquiries for wiring work to appointed district contractors, subject to the price being satisfactory and to the contractors purchasing supplies from the Council, again subject to the price not being less favourable than they could obtain elsewhere. It appears, however, that the purchases of stores from the Department by the contractors have been comparatively small, and the anticipated advantages to the Department have not been fully realised. The Electricity Committee now recommends that the district contractors' arrangements be terminated, and that in future consumers should be left free to select their own wiring contractor.

Scientific and Industrial Research.—A committee of the Privy Council for Scientific and Industrial Research is inviting various scientific societies to furnish statements indicating specific problems requiring scientific investigation. The Council of the Physical Society asks Fellows contemplating or prosecuting researches to communicate full particulars of them to the Secretary.

SUMMARY

MR. B. WELBOURN's address, as Chairman of the Manchester Section of the Institution of Electrical Engineers, was devoted to the production and properties of copper. Among other points dealt with was the effect of wear on the tensile strength of overhead trolley and electric railway wires (p. 460.)

THE B.E.A.M.A. are taking definite steps to ensure an active attack by us on German export trade after the war. This statement was made by the Secretary at an informal dinner last Thursday, when a clever review of German methods was given in a Paper by Mr. F. W. Wile (p. 460).

THE Engineering Standards Committee have now published their Report No. 72 dealing with British Standardisation Rules for Electrical Machinery (p. 461).

Two specifications of telephone relays and one relating to condenser circuits were published last Thursday at the Patent Office. Patents for resistances and intercommunication telephones expire this week after a full life of fourteen years (p. 462).

OUR Questions and Answers page this week deals with the comparative merits of two forms of multiplex armature windings (p. 462).

THE Harrogate Electricity Department is pushing the use of electricity for all domestic purposes, in conjunction with the rateable value tariff (p. 463).

PROFESSOR MARCHANT's presidential address to the Liverpool Engineering Society was on the subject of the relation of science to practice in engineering (p. 464).

SHORT articles deal with half-watt lamp fittings,

lighting and munition work, a shell inspection lamp, and a conduit spacing support (pp. 464 and 465).

MAINS and house services are required at Gravesend (£2,500); high-tension cable-testing outfit at Sydney; additional generating plant at Huddersfield; Diesel engine and generator at Pembroke, and mains and switchgear at Salford (p. 466).

A CONTRACT for power worth £20,000 per annum has been entered into by the Bradford Corporation.—The purchase of the electrical undertaking of the Tasmania Hydro-Electric Power & Metallurgical Co. by the Tasmanian Government is referred to (p. 466).

EDISON & Swan United Electric Light Co. and Drake & Gorham both show good results for last year (p. 466).

THE appeal of the Osram Lamp Works, Ltd., against the judgment of Mr. Justice Joyce, with regard to the alleged infringement of the Osram metal filament lamp patent by the Pope Electric Lamp Co. is now being heard (p. 466).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY COL. C. B. CLAY, V.D., COMMANDING.
Drills, 5.25 to 7.25; 7.25 to 8.25 p.m.

(To-day) Thurs., Nov. 18th: Sections III. and IV., signalling section, shooting.

Fri., Nov. 19th: Sections III. and IV., technical. Sections I. and II., squad or working party. Signalling section and recruits.

Sat., Nov. 20th: Uniform Parade, 3.0 p.m.

Mon., Nov. 22nd: Sections I. and II., technical. Sections III. and IV., squad, signalling section, and recruits.

Tues., Nov. 23rd: School of Arms with Architects Corps, 6.0 to 8.0 p.m.

Thurs., Nov. 25th: Sections I. and II. and Signalling Section, shooting.

Fri., Nov. 26th: Sections III. and IV., technical. Sections I. and II., squad, signalling section, and recruits.

The opening of the new Headquarters of the Corps will be held on Wednesday, Dec. 1st, 6.30 p.m. All members should make a special point of attending in uniform.

Volunteers for trench work on Sundays are requested to give early notice to their Section Commanders.

Arrangements for the Week.—(To-day) Thursday, Nov. 18th. Institution of Electrical Engineers. Presidential Address, by C. P. Sparks. Presentation of premiums. 8 p.m.

Saturday, Nov. 20th. Birmingham & District Electric Club, Swan Hotel, New Street. "Organising the Electrical Industry," by H. Foulds. 7 p.m.

Wednesday, Nov. 24th. Institution of Railway Signal Engineers. I.E.E., Victoria Embankment. 2.30 p.m.

Birmingham Section, I.E.E. University. "Some Difficulties of Design of High-Speed Generators," by Prof. A. B. Field. 7 p.m.

Diesel Engine Association. I.E.E., Victoria Embankment. Discussion on "Cracked Pistons."

Thursday, Nov. 25th. Institution of Electrical Engineers. "Some Difficulties of Design of High-Speed Generators," by Prof. A. B. Field. 8 p.m.

Faraday Papers.—At the meeting of the Institution to-night a valuable collection of Papers of Michael Faraday will be presented to the Institution in trust by Mr. D. J. Blaikley, who is the husband of the last surviving niece of Faraday.

COPPER FOR ELECTRICAL PURPOSES

M R. B. WELBOURN'S address as Chairman of the Manchester Section of the Institution of Electrical Engineers, which was delivered on Tuesday, consisted of an extremely valuable treatise upon the production and properties of electrolytic copper for electrical purposes—a subject which, we believe, has hitherto never been completely covered in a single publication.

In some introductory remarks Mr. Welbourn first congratulated Mr. C. J. Beaver, who is one of the Vice-Chairmen of the Section, for having carried off the highest award of the Institution last session for his Paper on "Cables" (ELECTRICAL ENGINEERING, November 19th, 1914, Vol. X., p. 597), and Mr. H. S. Marquand upon winning one of the Students' Premiums for his Paper on "Electric Welding." He also referred briefly to the war, mentioning that 1,100 out of 6,600 members are with the Forces, while a large proportion of the remainder are engaged on war service.

The world's output of copper is normally about one million tons per annum, this figure having been slightly exceeded in 1912. The United States produce 55 per cent. of the whole, and the whole of North and South America 73 per cent. Japan is the next biggest producer with 65,500 tons, and other countries' contributions are as follows: Spain and Portugal, 59,000 tons; Russia, 33,000 tons; Australasia, 47,000 tons; the combined product of Germany, Hungary, Turkey, and Bulgaria (when on a peace footing), 35,000 tons; and Great Britain 300 to 400 tons (although the production in 1860 was 15,968). The total production of the British Empire is close on 100,000 tons, being therefore about one-tenth of the world's output. The four biggest consumers in 1912 were: North America (365,922 tons), Germany (243,173 tons), Great Britain (147,551 tons), and France (106,753 tons).

About 70 per cent. of the world's copper output is refined electrically, and Mr. Welbourn first gave a brief but clear account of the various consecutive processes employed, dealing with the initial reduction and purification of the metal, its electrolytic refinement, and the processes of rolling, drawing, and annealing.

He next referred to the British, American, and International standards. The last-mentioned, which were published by the International Electrotechnical Commission in March, 1914, has not yet superseded the previous standard in this country, but has been adopted in the new Standardisation Rules of the American Institute of Electrical Engineers published last July. They fix the resistance of a standard annealed copper wire 1 metre long and 1 sq. mm. section at 20° C. at 0'0172414 (1/58th) ohm; the density of pure annealed copper at 20° C. as 8'89 grammes per c. cm.; and the temperature coefficient (at "constant mass") as 0'00393 at 20° C.

Mr. Welbourn recommends a standard for hard-drawn copper based on investigations made by Mr. D. R. Pye (*Journal of the Institute of Metals*, No. 2, 1911, Vol. VI.), and in accordance with the following empirical formula: A tensile strength in tons per sq. in. of 30–20 D, where D is the diameter in inches; and an extension on a marked 10-in. length (including the point of fracture) of not less than $e=5$ D, where e is the extension per cent. He is of opinion that a wire complying with this standard would also automatically comply with the British Post Office twisting test. Standards of elasticity should, he thinks, also be decided upon, given in terms of minima fixed for the ratio of elastic limit to breaking strength, i.e., the "limit of proportionality"; this varies from about 50 per cent. for wires of 0'08 in. diam. to about 70 per cent. for wires of 0'5 in. diameter. It is interesting to note that on stranded wires the effective strength is about 10 per cent. below that of the same number of straight wires, probably due to the difficulty of getting the strain evenly distributed among the wires of a strand, and the fact that the layers of wires are of unequal length.

Mr. Welbourn described some instructive experiments to ascertain whether there was a variation of tensile strength of hard-drawn copper wire due to wear. He started with a circular trolley wire 0'4 in. diameter, and turned six pieces down to different sizes down to 0'25 in., to ascertain whether the widely-held belief is correct that the hardness is due to the skin being hardened during the drawing process. The tensile strength remained practically constant. To find whether this was due to the wire being hardened in the lathe, he performed a similar series of experiments with a 0'25 sq. in. grooved contact wire for an electric railway, reproducing the wear by gently filing away the face. In this case the yield load actually remained constant while the sectional area was reduced from 0'246 to 0'207 sq. in., and was only reduced slightly when 0'195 sq. in. was reached; the actual yield stress in tons per sq. in. therefore actually increased.

Space has only permitted a brief abstract of Mr. Welbourn's excellent address, and we refer our readers to the fuller account which will appear in due course in the *Journal* of the Institution of Electrical Engineers.

Killed in Action.—Among the list of those killed in action on November 5th we regret to notice the name of Lieut. Nigel Crompton, the youngest son of Col. Crompton, C.B. Lieut. Crompton was with the 89th Field Co., R.E., attached to the 101st Company.

GERMAN—AND ENGLISH—BUSINESS METHODS

A T an informal dinner of the British Electrical and Allied Manufacturers' Association, an interesting Paper (read by the Secretary, Mr. D. N. Dunlop, in the absence of the author) was contributed by Mr. F. W. Wile, late Berlin correspondent of the *Daily Mail*. The subject was "German Business Methods as I knew them," but even more interesting than the brightly written and outspoken Paper itself was a statement by Mr. Dunlop that definite and far-reaching steps are already being taken by the Association to ensure an active attack by us on German export trade after the war.

Mr. Wile prefaced his review of German methods by explaining that he is an American, and "a neutral," that is to say, he is thoroughly neutral in so far as it is a matter of the most complete indifference to him as to how, when, where, or by whom Germany is crushed, so long as the process is prompt, decisive, and thorough. He is an American who feels that the guns of our Grand Fleet stand not only between German domination and the liberties of these islands, but between German tyranny and the freedom and security of the United States itself. He described German business methods as a strange combination of scientific efficiency and diabolical unreliability. Never in all his long residence in Germany could he reconcile the skill, enterprise, and industry of the average German business man with his incredible disregard for the elementary principles of honour. The music-hall joke of the year in Berlin four or five winters ago was the reply given by a comedian who was asked the meaning of "word of honour"; a "word of honour," he said, was something you gave when you did not want to bind yourself in a business way! The German does not live up to his word of honour in business because he is not expected to. A more subtle epigram, evolved by Mr. Wile himself, was: "A German always keeps his word because he cannot get anybody to take it."

If you go to Germany to give an order, Mr. Wile explained, a director who can talk English as well as you can will meet you at the station and entertain you luxuriously for a week, but you will not have gone half a day's journey toward home before your late opulent host will begin to plot to get the best of you under the contract, whose ink is not yet dry. He will only keep the contract if it is in his manifest interest to do so. The sacredness of a verbal promise is an utterly unknown quantity in Germany, and in the German language there is no such word as "gentleman." Imitation is a vaunted German commercial virtue. There is an immense traffic in illicit business information in Germany. An engineer or a department superintendent or a managing director will induce a bank to finance a competitive works purely on the assurance that, through his confidential knowledge, he is able to snatch the business of an older-established concern in whose employ he has been for many years, and often enough still is. It is considered perfectly ethical from a German banker's standpoint to supply funds for industries born under these criminal auspices.

Mr. Wile next referred to the praiseworthy features of German industrial organisation, and alluded to the passion of the German manufacturer for specialisation. To this is due his habit of employing an extraordinarily large number of engineers. An American engineer once told Mr. Wile that in a works employing 500 men it was not uncommon in Germany to find a staff of 50 engineers, who are content to devote their skill and energies indefinitely to a specific and more or less minor speciality, and to concentrate on developing it, instead of aspiring to generalise in the engineering field, even though thereby the status and emolument of the engineer might be considerably improved. This specialising mania of the Germans is all part and parcel of their infinite capacity for taking pains—a trait which has as much to do with their conquests in the foreign trade realm as any other one factor. The readiness of the German to make anything for anybody anywhere is one of the secrets of his international commercial progress. The German has always looked up to Great Britain as the master business mind and the Mecca of all those who would study commerce at the fountain head. No modern young German business man, at least before the "Gott strafe England" era, considered that he had had a proper start in life without personal acquaintance with the commercial practices of this country. The Allgemeine Elektricitäts Gesellschaft of Berlin, when it decided about ten years ago to go in for export trade on a broad scale, entrusted the organisation and management of that department to an English engineer, 31 years of age. When he took charge, the A.E.G. were doing £100,000 a year in export. When he left their service, at the outbreak of the war, they were doing £2,000,000. Yet, even though Germany has traditionally looked upon Britain as the mother of commerce and trade, the Germans have undoubtedly outstripped this country in respect of organisation. It is to the tremendous zeal and application of the German, especially in export trade, that his success is principally due. He is an insatiable student of the demands of the particular market on which he has designs. He puts its local customs, prejudices, and traditions under his microscope before he begins catering for its business. He learns, in particular, all there is

to know about its credit system, and prepares to accommodate himself to it. He will not be ashamed, if necessary, to wait three or five years for his money, where an Englishman, a Frenchman, or an American would not dream of extending credit for more than 90 or 100 days. German embassies and legations, besides being centres for purely diplomatic intriguing, are headquarters of the German business organisation in their particular capitals and countries. A German business man never appeals to them in vain for counsel or assistance. The German consular service throughout the world is a business-getting service pure and simple.

"I am aware," said Mr. Wile, "that British industry in general, and your own branch in particular, have concentrated during the past year on war and Government work. I know that this has seriously interfered with the prosecution of export trade; but unless you begin, now, to think of things after the war, I am very much mistaken if you will not find that the Germans have out-generalled you. You may be quite sure that, with their marvellous faculty for leaving no contingency unanticipated, the Germans are at this very hour busily planning and plotting for a new raid on the world's markets, of even a more determined character than any effort they have ever put forth in the past."

BRITISH STANDARDISATION RULES FOR ELECTRICAL MACHINERY

THE Engineering Standards Committee have now published their Report No. 72 dealing with new British Standardisation Rules for Electrical Machinery (excluding motors for traction purposes). This report supersedes Nos. 17 and 36, previously issued. The main features of the new rules were pointed out by us in a recent issue (October 21st), and now the report is published we are able to examine it a little more in detail. It is particularly pleasing to note that the new standards have been decided upon by the Engineering Standards Committee, not alone, but in co-operation and consultation with other bodies of international importance. The rules regarding temperature limits, for instance, are based on the limiting temperatures for insulating materials agreed to at the last Plenary Meeting of the International Electrotechnical Commission, held in 1913. The Committee has also had the benefit of the co-operation of the American Standards Committee, and a conference held in London, at which were present official representatives of the American Institute of Electrical Engineers, went far towards bringing about agreement on all essential details. At this conference the Canadian National Committee of the I.E.C. was also officially represented.

The Sub-Committee which has been entrusted with the drafting of these Rules, and of which Dr. R. T. Glazebrook, C.B., is Chairman, includes:—Messrs. C. H. Wordingham and L. J. Steele (representing the Admiralty), Capt. G. L. Hall, R.E., and G. H. Roberts (representing the War Office), H. C. Gunton (representing the G.P.O.), Llewellyn Preece (representing the Crown Agents for the Colonies), A. R. Everest, and C. Rodgers (nominated by the B.E.A.M.A.), John Christie (nominated by the Incorporated Municipal Electrical Association), W. Duddell, Dr. Gisbert Kapp, H. W. Miller, W. M. Mordey, C. H. Merz, W. H. Patchell, Capt. H. R. Sankey, R.E., Alexander Siemens, and Roger T. Smith.

With this weight of authority behind the report, and with the work done on an international basis, the new standards are likely to be universally recognised, and to become permanent in nature.

The Rules, which cover transformers, generators, and motors (except traction motors), are divided into 20 sections, dealing with types of machines, classes of rating, maximum cooling air temperature, measurement of temperature, embedded temperature detectors, limits of both temperature and temperature rise, tests for mechanical strength and stalling torque, dielectric tests, rating plate information, transformer terminal marking, &c. The subjects are dealt with very completely, the report containing 123 clauses.

The most novel feature of the rules, as we previously pointed out, is the adoption of the "continuous maximum" basis for rating, sometimes called the "single rating" basis. With regard to this, the report has a note that "it has been the general practice in the past to specify the output of electrical machinery intended for continuous service on the basis of a normal continuous rating with a definite over-load allowed for a limited period. The British Standard Rating as defined in these Rules, includes the equivalent of the previous over-load, and therefore only such momentary excess loads are recognised as are provided for in these rules."

In connection with this alteration of rating, it is interesting to note that the Committee make recommendations as

to the point of maximum efficiency for which the machine is designed, stating that this should be about 80 per cent. of the new rated output. Further, with regard to prime movers for generators, a note is inserted that "the most economical output of the turbine (i.e., the output at which it attains its maximum steam economy) should not correspond with the generator rating in kw., except under special circumstances. In general, it will be found preferable, when ordering a combined set, to specify that the most economical output of the turbine shall be equal to 80 per cent. of the kw. rating of the generator as defined in these Rules, i.e., equal to 80 per cent. of the maximum continuous output of the generator in kw. The average output of the alternator is usually something between three-quarters of the rated output and the rated output, and the average output of the combined set should clearly be the most economical output for the prime mover. . . . It should further be stated that, for mechanical reasons, the steam inlets should be capable, by means of bye-passes or otherwise, of dealing continuously with outputs 12 per cent. in excess of the rated output, which is 40 per cent. in excess of the economical output as defined above."

This note, it may be observed in passing, is typical of the excellence and thoroughness of the information given throughout the book.

With regard to the temperature of the cooling air for machines, it is noteworthy that a maximum value has been adopted instead of an average value as formerly. The Committee point out that the life of a machine depends to a great extent on the maximum temperature to which the insulation is exposed, and that this temperature depends on the load on the machine and also on the temperature of the cooling air. Therefore in order to establish the permissible temperature rise of a machine so as never to exceed the standard temperature limits, it is necessary to consider the maximum temperature to which the cooling air may rise, and the value of 40° C. has been adopted.

Full information is given in regard to temperature tests, and the methods to be adopted for the measurement of the temperature are also specified. In certain specific cases a thermometer measurement alone is specified; in some instances, in which the resistance method would be applicable, a thermometer alone may be employed, but with 5° C. reduction in the maximum temperature. The use of embedded temperature detectors, i.e., thermo-couples or resistance thermometers introduced during the building of the machine, is recognised for large machines.

The information to be given on the rating plate of a machine is set out in detail. A machine which fulfils the specifications of the standard rules is to have a distinctive special sign. Vector diagrams, for stamping on the rating plates of three-phase transformers, are included, and the methods to be adopted for the marking of the terminals of single and three-phase transformers are specified.

A particularly useful section of the report is that containing information which should be given with an inquiry, or when ordering machinery.

The Report will be most valuable, if not an absolute necessity, to designers, manufacturers, and users of electrical machinery, as well as to consulting engineers. The authoritative establishment of these standards will be a boon to the electrical industry, which has so long been in a state of confusion in regard to the matters dealt with, owing to the large number of standards in use and the numberless specifications produced that have had no regard for any standards.*

The Hefner Lamp.—We have received from the National Illumination Committee of Great Britain details of a research carried out by Dr. E. Ott and others, at Zurich, on the dependence of the light of the Hefner lamp on atmospheric conditions—more especially atmospheric pressure. The result shows that over normal ranges of pressure, i.e., from 816 to 716 mm., the reduction in the light is only about 1 per cent. for a reduction in pressure of 100 mm. of mercury. For the next lower 100 mm., however, i.e., from 716 to 616 mm., the reduction is as much as 7 per cent. The effect of aqueous vapour and carbon dioxide was very small, and it was uncertain, varying with the origin of these products, and the results of Dr. Ott's experiments show that these effects can generally be neglected if work with the lamp is performed in a large and well-ventilated room.

The "Generators."—On account of the conditions, it has been decided not to carry out the full programme this year, but in order to meet the wishes of a great majority of the members, a dinner will be held at the Trocadero Restaurant on Friday, December 3rd, for which an exceptionally attractive programme has been prepared.

* For the convenience of our readers we shall be pleased to send them copies of the report by return of post. The price is 10s. fid. (abt. 10s. 1d.). Orders, which should be accompanied by a remittance, should be addressed to the Kilowatt Publishing Co., Ltd., 203, Temple Chambers, E.C.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 11th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

21,096/14. Condenser Circuits. BRITISH INSULATED & HELSBY CABLES, LTD., and H. HIGHAM. In A.C. circuits, containing condensers, those designed to work at a higher voltage than that of the circuit are adapted to varying lower voltages by employing an inductance in series with the condenser, so that condensers of less capacity can be used than would otherwise be required. (One figure.)

1,694/15. Telephone Relays. WESTERN ELECTRIC CO., LTD. (*W.E. Co., U.S.A.*). Thermo-ionic amplifiers for telephone currents in which a maximum efficiency is obtained by placing the input electrode as close as possible to the source of ionisation or the cathode while sufficiently far to insulate it. (15 figures.)

8,903/15. Telephone Relays. V. TEDESCHI and A. G. ROSSI. A reversible relay for amplifying the energy of small periodic currents through the medium of mechanical work. The rotation of a solid continuous metal disc of high conductivity determines the inductive effect between two stationary identical symmetrical and insulated windings at right angles to each other and to the plane in which the disc rotates so that they shall not present any mutual induction when the disc is stationary. (9 figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: B.T.-H. CO. (*G.E. Co., U.S.A.*) [Moulded insulation composition] 24,419/14; RAILING and GARRARD [Cable joint boxes] 378/15; MIDLAND ELECTRIC MFG. CO. and BARBER [Distribution boards] 900/15.

DYNAMOS, MOTORS, and TRANSFORMERS: LA COUR [Rotary converters] 10,562/14; FALKENTHAL [Converters] 11,837/14; THOMPSON and M.L. MAGNETO SYND. [Coil winding machines] 22,639/14; YARWOOD [Motor starting] 7,244/15.

Heating and Cooking: CABLE ACCESSORIES CO. & REEVES [Heating element] 3,513/15.

Incandescent Lamps: H. G. FINCH and POYNTER [Incandescent

lamps] 16,850/14; SIEMENS & HALSKA A.G. [Carbon filaments] 4,776/15.

Storage Batteries: JACOBSON [Charging regulators] 21,509/14; WARD and RICHARD PAPE, LTD. [Storage batteries] 23,485/14.

Switchgear, Fuses, and Fittings: MIDLAND ELECTRIC MFG. CO. and BARBER [Switches] 21,761 & 21,978/14 & 901/15; IGRANIC ELECTRIC CO. (*Culver-Hammer Mfg. Co.*) [Controllers] 3,570/15.

Telephony and Telegraphy: SMITH [Telephone systems] 21,338/14; STRATFORD-ANDREWS and ORLING [Wireless receivers] 21,474/14; AGNER [Wireless telegraphy] 6,217/14; HACKETT [Telephone transmitters] 8,203/15.

Miscellaneous: SIGNAL GES. [Device for use with motors directly coupled to pumps, water sirens, &c.] 10,048/14; MELLERSON-JACKSON (*Commonwealth Electric Tool Co.*) 21,143/14; GREVILLE [X-ray apparatus] 21,609/14; THOFERN [Batteries] 5,395/15; BRIT. WESTINGHOUSE CO. [Vapour rectifiers] 8,173/15.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

23,456/01. Resistances. H. A. MAVOR and MAVOR & COULSON, LTD. Resistances comprising coils of wire held within a perforated insulating and fireproof body with the convolution spaced apart so as not to be touching.

23,838/01. Intercommunication Telephones. I. H. PARSONS and T. SLOPER. An intercommunication telephone system in which the conversation between any two stations cannot be overheard from a third station.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS, and TRANSFORMERS: E. C. KETCHUM [Homopolar dynamos] 16,729/06; J. H. HOLMES [Switch for short-circuiting slip-rings of induction motors] 17,520/09.

Instruments, Meters, &c.: B.T.-H. CO. (*G.E. Co., U.S.A.*) [Recording instruments] 17,763/09.

Switchgear, Fuses, and Fittings: B.T.-H. CO., H. BACON, and E. B. TUPPEN [Slow motion starters] 15,791/08.

Telephony and Telegraphy: W. AITKEN [Switches for private branch exchanges] 15,818/08; A. E. VICKERY [Electric order telegraphs] 1,948/09; C. BERARDI [Switches and indicators] 17,488/09.

Traction: RAILLESS ELECTRIC TRACTION CO. (*M. Schieman*) [Overhead collectors] 15,753/08.

Miscellaneous: H. P. & R. L. PÖRSCKE and G. WEDEKIND [Primer batteries] 16,751/04; METALLURGiska PATENT-AKTIE-BOLAGET [Magnetic separators] 16,780/07; J. E. NEWMAN and J. LODGE [Electrical treatment of plants] 17,046/07; F. STEINERT and H. STEIN [Magnetic separators] 17,490/09.

good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,469.

The lighting of a small hall is effected by 54 metal-filament lamps connected to a 100-volt A.C. supply of 50 periods per second frequency. What is the best method of using choking coils for dimming purposes, on two groups of 26 100-watt lamps and 20 32-watt? The remaining eight lamps are 40-watt, and require no dimming. How does the candle-power of a lamp vary with the applied voltage?

(Replies must be received not later than first post, Thursday, Nov. 25th.)

ANSWERS TO No. 1,467.

Explain the relative advantages and occasions for using duplex re-entrant (symbol ) and duplex non-re-entrant (symbol ) windings on direct-current armatures. Can equalising connections be fitted to either type, and if so, is it advantageous to do so?—"Enquirer."

The first award (10s.) is given to "Y.Z." for the following reply, which is printed in abridged form:—

The sort of case in which duplex windings might conceivably be useful is when an armature has to be made for a low voltage and a high current, a condition which would ordinarily lead to a very small number of commutator parts, necessitating very wide strips and difficult construction, as well as to very large armature conductors, commuting too much current in a lump, so to speak, and tending to produce a sensitive and difficult machine. One way of increasing the number of commutator parts and

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of

diminishing the current per armature circuit, is to use one of the duplex windings referred to in the question. Another case in which such a winding is useful is pointed out by Arnold, and is that in which, in a multipolar machine, the output and speed are such that neither a pure lap winding nor a pure wave winding is altogether good, the former because it has too many conductors, leading to bad space factor and other disadvantages, and the latter because it has too few conductors, leading to too few commutator parts and too great an armature current per circuit. The pure lap winding has as many circuits as the machine has poles, while the pure wave winding has only two circuits. By using a duplex (or other multiplex) winding, a compromise can be effected, and a number of circuits intermediate between those given by the pure lap and pure wave windings can be obtained which will give a suitable number of conductors on the armature. The first sort of case, that of low voltage, high current machines, leads to duplex (or multiplex) lap windings; the second sort of case, that of large machines where a compromise between lap and wave windings is required, with an intermediate number of circuits, leads to duplex (or multiplex) wave windings.

Coming now to the relative advantages of re-entrant and non-re-entrant windings, it may be said there is little to choose between them, but the preference on the whole is for a non-re-entrant winding. The chief fault of these windings is that the two parts are very liable to get connected together at unintended places, by reason of dirt collecting between commutator bars. This leads to bars being connected under a pole piece, instead of only at the brushes, and if a tooth comes between, differences of potential are set up which cause internal circulating currents to flow in the winding. Hence the windings should be kept clear of each other. Now the re-entrant type has naturally every bar connected to every other bar, and it is thus impossible to test out simply to discover the place where an unintended short circuit has taken place between the windings; but the non-re-entrant type is fairly easy to test out for this, because normally the windings are separate, and it is possible, by sending a current from one to the other through the short circuit, to find where the latter is by finding where the potential difference between the two windings is least. Hence for this reason the non-re-entrant type is better than the other.

As regards equalisers, these can be fitted in certain circumstances. For instance, in a duplex lap winding, if there are two coils side by side in a slot, and if these coils, at the other side of them, also lie in the same slot, so that a tooth never separates the pair of coils, equalisers can be put between two such coils at various points of the winding. If these be fitted, they carry any internal currents which would otherwise pass by the brushes and cause sparking. It is therefore a distinct advantage to fit equalisers. In the case of a duplex wave winding, the same sort of condition holds good. The writer had once to deal with a number of armatures which gave great sparking trouble, and found they were duplex wave windings, with, fortunately, two coils per slot. By bridging over between successive pairs of commutator bars, corresponding to pairs of coils in a slot, and so practically converting the winding into a single one with half the number of bars, the trouble disappeared entirely. Arnold deals very exhaustively with the subject of these equalisers, and declares that all windings of this sort must have equalisers in order to work.

Finally, if one is tempted to use these windings, let him follow historic advice, and don't! It is much better to use two commutators on a low voltage, high current machine, than one commutator connected to a duplex winding; and as for a multipolar machine, while it is true that places occur in a well-designed line where the difficulty appears which has already been indicated, i.e., the apparent unsuitability of both lap and wave windings of the ordinary sort, other devices are open to the experienced designer to get round this difficulty than that of adopting a winding which may prove in the end even worse than the alternatives it avoids.

The second award (5s.) is given to "F.M.D." for the following reply, which we have abridged:—

The winding represented by the symbol  is usually called duplex singly re-entrant, and  duplex doubly re-entrant.

Lap windings.—The rules for a lap winding are:—

Z , the number of coil sides, must be even.

T_f and T_b , the front and back winding pitches measured in spaces, must both be odd, must differ by " $2m$ " (" m " being the multiplicity), and should each be about one pole pitch.

Z/p , the re-entrancy (that is, the number of separate and distinct parts in the symbol of the winding), is the G.C.F. of $Z/2$ and " m ."

A duplex single re-entrant lap cannot be provided with equalising connections, for since Z is not divisible by $2mp$, neither can the number of commutator segments be divisible by $2p$, that is to say pairs of commutator segments exactly two pole pitches apart cannot be found. The rule for equalising connections is that they shall join only those segments which are separated by two, or a multiple of two, pole pitches.

In the case of a doubly re-entrant duplex lap winding there need be no difficulty in choosing Z so that equalising connections may be put upon each re-entrant section, but it is not advisable

to interconnect the two re-entrant sections unless this can be done by joining the back end of a coil belonging to one of the re-entrant sections to the front end of the adjacent coil of the other section. This connection makes the potential of each commutator segment midway between the potentials of the two adjacent segments.

Wave windings.—The simplest possible form of wave winding is one which, advancing two spaces each time it completes a tour of the armature, closes after advancing exactly one double pole pitch. A duplex wave winding consists either of two of the simple waves just spoken of, in which case it is called doubly re-entrant, or it consists of one winding which advances two double pole pitches before closing, and is then called singly re-entrant. A simplex wave winding demands only two brushes, each thick enough to bridge over one commutator segment; a duplex wave may have either two brushes only, each brush bridging over two segments, or four or more brushes of single thickness. In either case equalising connectors should be provided. These serve in the first case to interconnect the re-entrant sections, and in the second case to interconnect corresponding points on the two plexes (or folds) of the winding. Corresponding points are points separated by two or a multiple of two pole pitches. It is not easy to explain in few words why equalising connectors should be needed upon a multiplex wave winding, but their use is found to improve the commutation.

Modern practice avoids the use of multiplex windings, whether lap or wave, and when they have to be used it is essential to provide them with equalising connectors (connection often being made to every third or fourth segment). The occasion for their use arises when it is desired to use many coils of thin wire, rather than half the number in thick wire. Consequently, they are used upon two-pole machines of high current output (say, over 200 amperes). And whenever the number of poles is insufficient to allow a simple lap winding to be used, the designer may be tempted to use a duplex lap. Better practice is to increase the number of poles so that the desired current may be taken from a simplex lap winding.

In spite of the supposed advantage that with a duplex winding only one half the current is being commutated at the brush tip at any instant, duplex windings are in practice liable to commutation troubles.

ANSWER TO CORRESPONDENT

H. TURNER.—(1) If you will inquire at the Patent Office, Southampton Buildings, London, W.C., they will give you the necessary forms for applying for a patent, and a list of the fees. You can also consult all existing patents at the library at the same address without charge. They are well indexed. (2) Mr. J. G. Lorrain, Staple Inn Buildings, High Holborn, W.C.; Mr. J. E. Raworth, 69-71 Queen Anne's Chambers, Westminster, S.W.; and Messrs. W. P. Thompson & Co., 285 High Holborn, W.C., are all reliable patent agents. (3) Whether it is a good time to exploit the patent depends on the subject. You must use your own discretion. (4) Good books are "A Handbook of Patent Law of all Countries," 2s. 6d., by post 2s. 9d.; "The Inventor's Adviser on Patents, Licenses, and Trade Marks," price 5s.

ELECTRICITY IN THE HOME

WITH this title Mr. G. Wilkinson, the Borough Electrical Engineer at Harrogate, has issued an attractively got-up booklet dealing with applications of electricity in the house. There is some interesting talk on the advantages of the rateable value tariff, which in Harrogate is a fixed annual payment equal to 15 per cent. of the rateable value of the premises, one quarter of which is invoiced quarterly, and $\frac{1}{4}$ d. per unit for all electricity consumed. For water heating and like apparatus having 100 per cent. load factor with automatic control, current is supplied on contract at $\frac{1}{4}$ d. per unit.

As showing the advantages of the tariff, an example is given of a house in Harrogate let at £60 per annum. In 1913 the kitchen range and boiler were removed, and the house was equipped as an "electric household" as follows:—Complete kitchen arrangement, including electric cooker and automatic electric hot-water apparatus capable of furnishing a maximum of 125 gallons of hot water (at 100° F.) in 24 hours. Eight rooms were fitted with plugs for electric fires, including four bedrooms and the bathroom. One fixed and three portable radiators were provided, as well as plugs for an electric vacuum cleaner on each floor. For supplementary heating in the cold weather a slow combustion coke boiler was installed in the basement, and hot-water radiators fixed in the entrance and rooms on the ground and first floors. In the coldest weather coal fires in slow combustion grates are used in place of the electric fires in the living rooms. These labour-saving improvements allowed of one maid being dispensed with, and the actual comparative expense, taking the average of two years, on the rateable tariff, showed a saving of £10 16s. 9d. per annum. At the same time, Mr. Wilkinson anticipates a substantial saving in current used for heating by the addition of automatic temperature regulators on the radiators.

Information is given on the various apparatus, and at the conclusion the names and addresses of the local electrical contractors are set out.

SCIENCE AND PRACTICE IN ENGINEERING

AT the opening of the present session of the Liverpool Engineering Society, Professor E. W. Marchant, D.Sc., delivered his presidential address on "The Relation of Science to Practice in Engineering." He emphasised Dr. Unwin's recent statement that it was to the application of scientific method that Germany held the position she had attained in engineering constructional work during the past twenty years.

As an instance of the effect of scientific study in one particular direction, the case of transformer manufacture was referred to. By the discovery of alloyed steel of high electrical resistance and good magnetic qualities, and by the scientific study of the most effective method of getting rid of waste heat, the cost of transformers during the past twenty years had been reduced from about £2 10s. to 10s. per kilowatt.

The value of laboratory research to manufacturing progress was enlarged upon. Whilst the laboratory had a limited scope in respect of the size of machinery it could deal with, and therefore limited functions in the field of research, nevertheless it had a definite place in this field. The work of laboratory research might be classified under three headings, the investigation of (1) the properties of materials, (2) the origination and design of machinery and apparatus, and (3) entirely new phenomena, with a view to their development for practical use. With regard to the first of these, the speaker dealt with the progress made in the manufacture of copper. Copper used nowadays was of 2 or 3 per cent. better conductivity than Matthiessen could produce in his laboratory. The presence of traces of such substances as arsenic or phosphorus had been found to reduce the conductivity of copper enormously. A most interesting example of the advantage of co-operation between the manufacturer and the physicist was given by the researches undertaken in Professor Barrett's laboratory at Dublin on the properties of iron alloys. These alloys, in which different substances such as tungsten, nickel, manganese, silicon, aluminium, &c., were alloyed with steel, were produced at the Hecla Works of Sir Robert Hadfield at Sheffield. These investigations led to the valuable discovery of the magnetic qualities of silicon and iron alloys of which "Stalloy" was one.

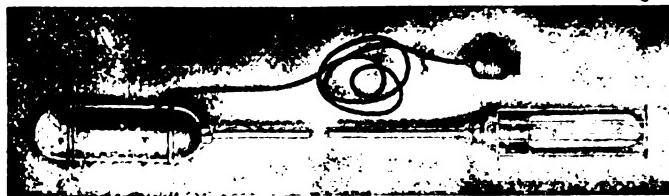

References were also made to the production of hard steel for magnets, and of manganese non-magnetic steel, to the investigations of the properties of insulating materials, and the improvement of transformer oil in the matter of sludging.

In connection with the investigation of machines and apparatus, the speaker referred to the building up of an individual magneto manufactory since the outbreak of war. This industry had been almost entirely in the hands of Germany, but as the result of a scientific design of magneto, the firm in question would soon be turning out from 1,000 to 1,500 machines per week, mostly for British and Allied Governments. Reference was also made to Professor Miles Walker's recent discovery of a new commutation device, by which the output of certain machines could be very greatly increased.

Professor Marchant said, in conclusion, that they must be prepared after the war was over for a fierce and unscrupulous war of commerce, not only with Germany, but with other countries less highly developed. They would have to make full use of their scientific knowledge, so as to save every penny they could of unnecessary expenditure in material or in labour.

A SHELL INSPECTION LAMP

NOT the least remarkable feature of modern shell construction is the minute care with which every part is inspected at each stage of its construction. One of the most important, and certainly one of the most awkward, of the inspection operations is that of examining carefully the interior of the shell, and to facilitate this operation the British Thomson-Houston Co., Ltd., of Mazda House, 77 Upper Thames Street,

E.C., have brought out the very workmanlike hand lamp shown in the accompanying illustration.

A stout brass wire guard with top and bottom plates forms a "squirrel cage" accommodating a tubular lamp $4\frac{1}{2}$ in. by $1\frac{1}{2}$ in. This guard, which can be removed if required, is carried in the usual manner by a bayonet lamp-holder mounted on a brass carrier rod. At the outer end of the latter is a boxwood handle, carrying a push-bar switch. The lamp is

supplied as illustrated, ready wired with 12 ft. of 35/40 work-shop flex to a coccus adapter. An important point is that where an ordinary electric light supply is not available, the new inspection lamp, equipped with one of the many types of Mazda miniature bulbs, can be worked from a low-voltage accumulator or even dry cells.

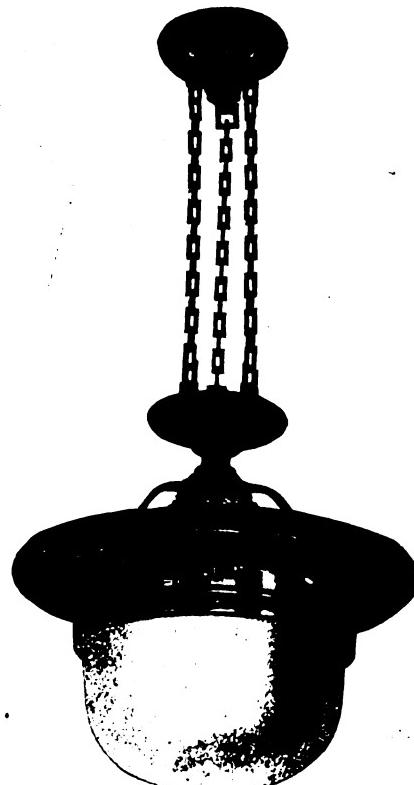

"SIMPLEX" HALF-WATT LAMP FITTINGS

THE introduction of the half-watt lamp has necessarily demanded a new type of fitting, and Simplex Conduits, Ltd. (Garrison Lane, Birmingham), have lost no time in designing some new patterns, of which we illustrate two. It is fortunate that the nature of the half-watt lamp enables fittings to

SHOP-LIGHTING FITTING.

be made more attractive in appearance than was possible with the arc lamp, and this applies equally to the inexpensive enamelled iron type for outside use as to the more elaborate designs for private house, shop, or public building lighting. In the designs illustrated, whilst consideration has been given

INTERNAL LIGHTING FITTING.

to appearance, much thought has also been given to mechanical suitability. Special care has been taken, both in the ventilating and weatherproofing of the outside lantern. The special glass used in more elaborate designs is the result of considerable experiments, and the aim has been to secure a maximum of light with the minimum of glare.

EDISWAN "ANTI-ZEP" SCREENS

WE illustrate an "anti-Zep" screen designed by the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex), to meet the shaded light regulations now in force in various parts of the country. Every attention has been given to its effectiveness and strength, only the best dark green sateen and trimming being used. Shades as well as screens are supplied.

EDISWAN "ANTI-ZEP" SCREEN.

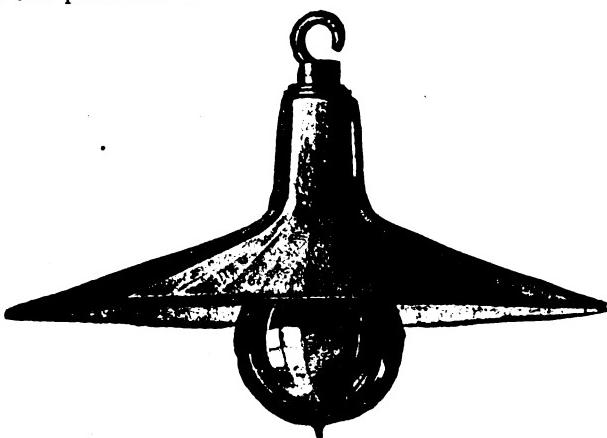

LIGHT AND MUNITION WORK

ONE of the most important points brought out in the report of the Departmental Committee on Factory Lighting was the enormous difference in output which experiments showed

MUNITION SHOP PENDANT.

could be effected by scientific artificial lighting. At present, when probably nine out of ten British factories are engaged in the production of munitions of war in one form or another,

HALF-WATT LAMP FITTING.

satisfactory lighting cannot be over-estimated. The general recommendations of the Committee were given on p. 378 of our issue for September 16th, but it cannot be emphasised too much that good artificial lighting increases output anything from 10

to 20 per cent. It also reduces the risk of accident, and the tendency is for accident insurance companies to accept lower premiums in respect of premises lighted on really scientific lines. The change from rule-of-thumb methods to science is taking place rapidly in illumination, and, recognising this, the General Electric Company, Ltd. (67 Queen Victoria Street, E.C.), has established an illuminating engineering department to undertake research work and provide expert advice on all lighting problems. This department is fully equipped to design new lighting installations for every type of factory or workshop. It is also prepared to draw up schemes for improving existing installations.

At the same time, the Company is developing the manufacture of electric lamps and fittings, and, in addition to the Osram lamp and the later "Atmos" half-watt lamp, an extensive range of reflectors and fittings specially designed for factory purposes has been produced. We illustrate two types of these. Any factory owner who is dissatisfied with his illumination, or is uncertain whether it complies with the standard of efficiency which the Home Office Committee has defined, has only to seek the advice of the General Electric Co.'s new Department. The cost of a new installation or the re-arrangement of an existing one is trifling in view of the increased output which experience has shown to be possible as mentioned above.

A CONDUIT SPACING SUPPORT

THE conduit spacing support illustrated is intended for use in cases where conduits are run on the surface of brick, stone, or cement walls. The rag bolts should be well grouted into the wall, and the hole filled with Keene's cement

up to the shoulder. The conduit will then be spaced out a clear $\frac{1}{2}$ in. from the surface. Simplex Conduits, Ltd. (Garrison Lane, Birmingham), are placing these on the market at very reasonable prices.

CATALOGUES, PAMPHLETS, &c., RECEIVED

OSRAM PRICE LIST AND FOLDER.—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), has now issued its price list and folder bearing the picture of the gas-fitter, illustrated on page 449 of our November 4th issue. These the company is, as usual, willing to overprint for electrical contractors, dealers, and ironmongers.

"THE HOUSE BEAUTIFUL."—Under this title Ferranti, Ltd. (Craven House, Kingsway, W.C.), has just published a booklet in which is depicted the use of electric fires in all rooms in the house. The booklet is addressed mainly to those desiring to introduce all possible comforts and conveniences into their houses, but contractors will certainly find it of great assistance in facilitating business.

INDUSTRIAL LIGHTING FITTINGS.—A new leaflet has just been issued by the General Electric Co., Ltd. (67 Queen

Victoria Street, London, E.C.), dealing with a number of industrial lighting units suitable for use in different positions in factories and workshops—special attention having been given to ensure that the present lighting regulations are complied with.

"BRITANNIA" LAMP SHADES.—Messrs. Dick, Kerr & Co. (Abchurch Yard, Cannon Street, E.C.) is prepared to give free to applicants "Britannia" lamp shades which have been designed to comply with the present lighting restrictions. When in position they make an effective reflector and shade. The Company has also issued a home and export list of "Britannia" metal filament lamps setting forth prices, &c.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Aberdeen.—The Electrical Engineer is to report upon extensions to the generating plant.

Australia.—The Sydneyp municipality requires a high-tension cable-testing outfit, consisting of a 350 k.v.a. single-phase transformer, a 175 k.v.a. single-phase potential regulator, a 1,600 k.v.a. single-phase inductance, and a control switchboard. Preference will be given to British manufacturers. Tenders by Nov. 22nd. This information is only of value to firms who can cable agents. A copy of the specifications may be seen at 73 Basinghall Street, E.C.

Downham Market.—The Council is considering a proposal by Mr. C. H. Best, of Bradford, to form an electric supply company for the district.

Edinburgh.—Estimates aggregating about £25,000 for water-softening plant at the new power-house have been submitted.

Fakenham.—Mr. C. H. Best, of Bradford, has been informed that the Council will not oppose his proposal to form a company to erect an electric supply works in the district.

Gravesend.—The Engineer reports the necessity for applying for further loans to cover mains extensions and house services during the next two years. The estimated cost is put at £2,500.

Huddersfield.—It is stated that in spite of the extensions which were installed a short time ago, the electrical undertaking is not able to cope with the private demands for power.

Pembroke (Ireland).—A Diesel engine and generator is required.

Salford.—An expenditure of £500 is contemplated upon mains and switchgear in connection with a supply to a local firm.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £91 10s. to £92 10s. (last week, £90 to £91).

Agencies.—The representative of a firm of machinery importers and agents in Melbourne, at present in the United Kingdom, is desirous of making arrangements to represent United Kingdom manufacturers of electrical machinery. Further particulars at 73 Basinghall Street, E.C.

APPOINTMENTS AND PERSONAL NOTES

Mr. B. G. Lamme, Chief Engineer of the Westinghouse Electric & Manufacturing Co., Pittsburg, has recently been appointed a member of the U.S.A. Naval Advisory Board.

Mr. W. T. Roper, Manager of Messrs. Verity's, in Dublin, has been granted a commission in the Army Service Corps.

Mr. H. G. Barracough, Generating Engineer at the Hackney Electricity Works, has resigned.

An Electrical Mechanical Engineer is wanted for an Indian colliery. (See an advertisement on another page.)

LOCAL NOTES

Bradford: *Important Power Contract.*—The Electricity Committee has made arrangements to supply power to the extent of £20,000 per annum to new works which are to be constructed alongside the Midland Railway on land belonging to the Corporation.

Otley: *Electric Supply.*—The Council obtained an electric lighting Order in 1901, but although various schemes have been placed before it, nothing has been done with regard to a supply of electricity for the district. Now, however, an offer by the Electrical Distribution of Yorkshire to apply for an electric lighting Provisional Order has been accepted.

Southport: *Electricity Profits.*—There was a net profit of £2,213 on the electrical undertaking last year, an increase of £350 over the previous twelve months. The number of units sold increased by 340,000.

Tasmania: *The Hydro-Electric Scheme.*—A report by H.M. Trade Commissioner in Australia for 1914 records that the Tasmanian Government has entered into an agreement with the Hydro-Electric Power & Metallurgical Co. for the purchase of the electrical portion of its undertaking. At present some 26,000 h.p. can be generated for twelve hours per day, but this amount could be increased. Works which have been under construction for some time will be completed early next year. It is understood that the Tasmanian Government has offered to supply the Federal Government with power at £2 per h.p. per annum.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Edison & Swan United Electric Light Co.—After providing for debenture interest and depreciation upon freehold properties and plant there is a net profit of £14,147 for the year to June 30th, to which is added £5,732 brought forward. The directors propose to transfer £15,000 to reserve and to carry forward the balance. The necessity for creating a substantial reserve account is pointed to as the reason for the non-payment of a dividend. The increased turnover of the business, coupled with the rise in the cost of materials and labour, have severely taxed the capital resources of the Company, and the allocation to reserve is regarded as the only means of providing additional working capital. Whilst on the engineering side the extra cost of manufacture has been partially met by a corresponding rise in selling values, an increase in the selling price of drawn wire lamps is impossible. The export business, particularly to the British Colonies and India, shows a marked increase.

Drake & Gorham.—There was a net profit of £3,816 for the year to June 30th, after meeting bonuses due to staff, allowances to those who have joined the forces, and making provision for contingencies. A dividend of 2½ per cent. per annum is declared on the ordinary shares, goodwill is written down by £1,000, and a balance of £1,623 is carried forward.

At the annual meeting last week, Mr. B. M. Drake, the Chairman, stated that the Manchester office had shown disappointing results for the past year, the installation profits being less than a third of those of the previous year. Nevertheless, the amount of work in hand at the close of the year was largely in excess of the previous year's record. The country house lighting department has also been considerably affected by the war, but the wholesale department has held its own well.

The Osram v. Pope Patent Action.—The appeal of the Osram Lamp Works, Ltd., against the judgment of Mr. Justice Joyce, given on July 20th (ELECTRICAL ENGINEERING, July 22nd, p. 311), in which it was held that the process employed by Pope's Electric Lamp Co., Ltd., in the manufacture of their metal filament lamps, does not infringe the Just & Hanaman patent No. 23,899/04, was commenced on Thursday, before an Appeal Court, consisting of the Master of the Rolls, Lord Justice Warrington, and Lord Justice Bancks. The case will occupy a considerable time, and we will refer in greater detail to it in our next issue.

SUMMARY

THE Manchester Engineers' Club has now formulated definite proposals for the organisation of the engineering industry. An association, on a non-trading and "non-interference-with-prices-basis," of British manufacturers in all branches of engineering is recommended (p. 468).

MR. Howard Foulds, Secretary of the Birmingham Corporation Electric Supply Department, in a Paper before the Birmingham and District Electric Club on Saturday, advocated the establishment of a Commercial Electrical Association (p. 468).

WE record the progress made by the Engineering Institutions' Volunteer Training Corps (p. 468).

IN his Presidential Address to the Institution of Electrical Engineers, Mr. C. P. Sparks advocated the abandonment of the principle of the lowest tender. The major part of the address consisted of an able review of the development of the electricity supply industry, marking very clearly the important steps in its progress and indicating the directions in which further advance might be anticipated (p. 469).

A PAPER recently read before the Indiana Electric Light Association emphasised particularly the value of electric vehicles as a means of filling up the hollow in the load curve which occurs during the midnight and early morning hours (p. 470).

AMONG the subjects of Specifications published at the Patent Office last Thursday were incandescent lamps, insulating compounds, carbon filaments, and vapour rectifiers (p. 471).

AT the Birmingham Section of the I.E.E. last night Professor A. B. Field read a Paper on "Some Difficulties of Design of High-speed Generators" (p. 471).

OUR Questions and Answers page this week deals with the best method of making a temporary alteration in the speed of a shunt motor (p. 472).

IN the Chairman's Address to the Scottish Local Section, Mr. D. A. Starr anticipates a busy time for the electrical industry after the war (p. 473).

AT the Newcastle Section of the I.E.E. on November 8th Mr. P. V. Hunter read his Chairman's Address on the design of power-station switchboards (p. 473).

PRACTICAL advice as to the running of storage batteries is given by Mr. R. Rankin in a Paper before the Association of Supervising Electricians (p. 473).

THE desirability of the formation of a Board of Industry, and a closer interest by the State in trade and technical education, were among the subjects discussed by Mr. H. H. Wright in his Chairman's Address to the Yorkshire Local Section (p. 474).

A VALUABLE collection of Papers left by Faraday was presented by one of his relatives to the I.E.E. last Thursday (p. 474).

NEW plant is required at Coventry (£30,278); a 5,000-kw. turbo-alternator at St. Pancras; mains at Islington and Woolwich; electrically-driven centrifugal pumps at Sydney (N.S.W.); and new generating plant at Bo'ness.—A quantity of telephone material is required in Australia (p. 475).

THE L.G.B. has refused to interfere with the development of the Barton power station of the Manchester Corporation (p. 476).

A SATISFACTORY year with Ediswan metal-filament lamps was reported at the annual meeting (p. 476).

For V.T.C. Orders and "Arrangements for the Week" see p. 476.

SUBSCRIPTION RATES.

The postage on ELECTRICAL ENGINEERING is unaffected by the new postal regulations, and the subscription for the United Kingdom is as hitherto, 6s. 6d. per annum, post free.

REDUCED SUBSCRIPTION RATES FOR COLONIES AND ABROAD.

The subscription in future will be 8s. 8d. per annum, post free, instead of 13s. All subscriptions are payable in advance.

Orders should be addressed to and cheques made payable to—

THE KILOWATT PUBLISHING CO., LTD.,
Temple Chambers, London, E.C.

ORGANISATION OF THE ENGINEERING INDUSTRY.

AS we have already mentioned, the Engineers' Club of Manchester has had under consideration the present situation of the engineering industry and the best means for dealing with it, having regard to the position revealed by the war. On page 118 of our issue for March 18th we pointed out that a sub-committee had reported, and had made a certain number of recommendations as to future policy. Subsequently a special committee was appointed to consider the whole matter and report fully to the Club. A copy of this report has now been sent us, and in general it follows the recommendations of the sub-committee.

The Committee is convinced that the British engineering industry must organise without delay to take advantage of present opportunities and to meet the conditions which will follow the termination of the war, it being anticipated that our enemies, whose export trade has for the moment practically disappeared, will renew with increased fervour their characteristic methods of conducting a trade war against our industries. The proposed organisation, as we have already described it, is to be on a non-trading and "non-interference with prices" basis, comprising British manufacturing concerns in all branches of engineering. Such an Association, it is thought, would speak with a powerful collective voice in Parliament, would assist the Government in questions connected with industry and commerce, and would be entitled to representation on the governing bodies of universities and technical colleges. It is pointed out that the trifling subscription of one-tenth of 1 per cent. upon the £300,000,000 capital invested in the British engineering industry would provide an income of no less than £300,000 per annum. The general management of the Association would be in the hands of a competent business man under the direction of a representative and periodically elected council, the headquarters being in London or Manchester. The scheme provides for the establishment of branches at suitable centres in this country and others later on, the local representative being in close touch with the British Consul, the Commercial Attaché, the Colonial Governments, and the British Chambers of Commerce.

The scope of the Association is that already recommended by the sub-committee, although the classification is slightly different, it being now proposed to have standing committees in regard to the following departments, namely, General Purposes; Intelligence; Production; Inventions and Patents; Publicity; Finance; Education and Research; and Parliamentary.

This report was discussed by the members of the Manchester Engineers' Club on Friday, and it will be seen that if the scheme is to be adopted and worked practically, it would involve the disappearance of a large number of existing organisations, such as the B.E.A.M.A. and the British Engineers' Association, not to mention others. The scope of the recommendations is intentionally large and ambitious, because the Committee is convinced that half measures will not command general support. The aim is organisation of the whole engineering industry, so that it may help itself. Although the recommendations are the result of a year's discussion, not only by the Committee, but by many distinguished engineers and men of commerce, who have come from different parts of the kingdom to take part in the debates, yet one is bound to remind the Committee that the scheme is not only wide in itself, but practically involves putting all existing organisations of a similar character in the melting-pot and starting afresh.

A COMMERCIAL ELECTRICAL ASSOCIATION

AT a meeting of the Birmingham Electric Club on the 20th inst. Mr. Howard Foulds, the Secretary of the Birmingham Electric Supply Department, in a Paper upon "Organising the Electrical Industry," advocated the formation of a Commercial Electrical Association. He pointed out the disadvantages of having a large number of bodies dealing individually with work the major portion of which was common to all of them, and thought it would be infinitely better if there was one large Association for the protection and development of the commercial side of the electrical industry. All the existing bodies had the core of something useful, but none of them were doing anything which had a sufficiently important result upon the development of the applications of electricity to industry and commercial uses. What he was really anxious about was that we should establish a body which shall be *prima facie* a commercial association. The nucleus of such an association already existed in the B.E.A.M.A., but something more than this was required. We required in addition a strong association of supply undertakings, including the companies as well as the municipalities,

and further, a sound financial section, which would if necessary provide the funds for extending industrial undertakings. One of the most common remarks heard from the lips of industrial men in this country was that the banks do not support the trade of the country. It appeared to him, however, that it was the business of substantial industries to create their own financial institutions.

As an instance of the absence of organisation in the electrical industry at the present time, he instanced Birmingham. In that city there were some of the largest manufacturing companies in the electrical industry, and yet there was not an association to which anybody could go and say, "I want to know the electrical manufacturers of Birmingham. I want to know something about them, their particular lines of business, their status, and things of that kind." He might go to the Electric Supply Department and get some information there; he might look it up in the directory, or he might go to the Chamber of Commerce, but, in spite of the strength of the Birmingham Chamber of Commerce, which numbers 3,000 members, it had not an electrical section.

The proposed new association should consist of three main sections: (1) Manufacturing and contracting; (2) supply of electricity; (3) financial. Each section would have several sub-committees dealing with the different branches. In addition there ought to be a Benevolent Fund, and this would appeal to a much wider body than either the I.E.E. or the Electrical Trades Benevolent Fund; in fact, the latter might be taken over.

It was not, however, merely protection that such an association would ensure; it ought to have so wide an influence as to be able to carry through Parliament the very necessary amendments to existing Acts of Parliament, whose conditions hinder the development of the uses of electricity. It would stand immensely superior to any of the existing bodies or any temporary body perhaps created for some specific purpose. It was once said by a President of the Board of Trade that no Government is strong enough to resist the Association of Municipal Corporations. He believed, if we organised ourselves on a proper basis and found funds, it could be truthfully said that no Parliament would be a match for the Commercial Electrical Association.

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

THE first meeting of the General Committee took place recently, those attending including the Presidents of the Institutions of Civil, Mechanical, and Electrical Engineers, Sir John Gavey, Mr. J. S. Highfield, Col. Le Rossignol, R.E., Major Henrici, R.E., Capt. Sankey, R.E., Mr. L. B. Atkinson, Lieut.-Colonel C. B. Clay, V.D. (Commandant), and Mr. E. G. Fleming, Adjutant. An Executive Committee was formed consisting of Sir John Snell (retiring President of the Institution of Electrical Engineers), Chairman, Sir Maurice Fitzmaurice, C.M.G. (Vice-President of the Institution of Civil Engineers), Col. Le Rossignol, R.E., Lieut.-Colonel C. B. Clay, Mr. L. B. Atkinson (Hon. Secretary and Treasurer), Mr. E. G. Fleming, and a representative of the Institution of Mechanical Engineers to be nominated by the President.

The report of the Commandant as to the progress of the Corps was most encouraging. An arrangement has been made for sharing headquarters with the 4th Battalion City of London Regiment (Architects' Corps). The premises comprise a spacious drill hall with mess rooms, common room, orderly room, canteen, &c. Through the kindness of Mr. A. A. Campbell Swinton, F.R.S., the Corps has received a present from Messrs. Crompton & Co. of a new Admiralty pattern searchlight. This is being erected on the premises of the London Electrical Engineers (T.F.), where the necessary instruction will be given. Several men have already qualified in this branch, and parties are engaged each week-end on important work in connection with the defence of London.

In inviting suitable men to join the Corps, it is pointed out that only those who are over military age, or disqualified by reasons of health, or who are engaged on war work and not allowed to enlist in the forces, are acceptable.

Electric Power Stations and Munitions.—In the House of Commons last week Dr. Addison, speaking on behalf of the Minister of Munitions, said that it is hoped to deal with the question of taking over, as controlled undertakings, electric power stations and similar businesses essential to munition works in a Bill to be shortly laid before Parliament.

"The Central."—The last issue of *The Central* contains a Paper by Prof. W. E. Dalby on the recent extension of the City and Guilds Engineering College, read at last year's B.A. meeting in Australia, and a Paper on High Tension Power Transmission, read by Mr. B. Hague before the College Engineering Society. The Old Student Notes are particularly interesting at the present time. With the number a list of the past and present students known to be serving with His Majesty's Forces up to last May has been issued.

THE PRESIDENTIAL ADDRESS

Commercial Engineers, Lowest Tenders, and Progress in Electricity Supply

THE inaugural meeting of the new session of the Institution of Electrical Engineers was held last Thursday. After the presentation to the Institution of the Faraday Papers, reported elsewhere in this issue, and the distribution of the premiums and prizes awarded at the end of last session (a list of which was published in ELECTRICAL ENGINEERING of May 20th, p. 213), Mr. C. P. Sparks, the new President, delivered his Address.

After 15 months of war on an unprecedented scale, he said, the present need is not less urgent: the last recruit and the last round of ammunition will be the deciding factor. While the bulk of our 7,000 members are engaged in maintaining the public services or, directly or indirectly, the manufacture of munitions of war in comparative safety, our hearts go out to the 1,150 members of the Institution who are on active service in answer to the national call.

As one-half of my career has been spent in the manufacture of electric supply plant, and the other half as engineer to electric supply undertakings, Mr. Sparks continued, I desire to say a few words on a subject of special interest to all sections of the Institution. It is sometimes suggested that commercial matters should not be dealt with by engineers, who should confine themselves to technical questions. I disagree with this view, and believe that the commercial engineer is just as much a recognised member of our profession as a pure scientist. Now, as to the acceptance of the lowest tender, whether it be British or foreign, it must always be remembered that the onus of development and the successful carrying out of a contract is borne by the contractor, and that if a reasonable margin of profit is not secured, the contractor cannot in the long run do his duty by the purchasers. First, the contractor is crippled, being unable to make provision for development, since without profit new capital cannot be attracted; but, what is more serious, provision cannot be made for improvements, without which we cannot keep pace with our world competitors. The national interest would be better served by encouraging private enterprise to develop invention, by allowing manufacturers a reasonable margin of profit, than by securing—for the moment only—slight fractional reductions in the cost of public service undertakings through acceptance of the lowest tender, which is not always necessarily the most favourable.

Mr. Sparks then followed the example of many previous Presidents in reviewing the position of the section of the industry in which he has been most closely associated, and gave an extremely interesting sketch of the development of electricity supply, particularly in relation to London itself.

He recounted the early history of electric lighting in London, and mentioned how development had been seriously retarded by splitting up the Metropolis into many areas, by making it more or less essential at first for traction undertakings to erect independent generating stations, by the treatment of the London Electric Supply Corporation in refusing its powers for bulk supply in 1888 and allowing competition in its main area, and by the rejection by Parliament of the Merz bulk scheme in 1905.

Some interesting tables showed how electricity supply had developed in London notwithstanding. In the area of 117 sq. miles covered by the metropolis, 334,442,700 units were sold in 1914, as compared with 14,206,900 in 1894, the revenue for the sale of electricity had increased from £352,830 to £2,742,400, and the average revenue per unit had decreased from 5·96d. to 1·97d. The capital expenditure up to 1914 was £21,813,500—about one-third by local authorities, and two-thirds by companies—and the average density of the sales (apart from traction) is 3 million units per annum per sq. mile, reaching 45 units per sq. mile in the area of densest demand. Another interesting figure was that, in spite of the introduction of metal filament lamps, the sales during the past ten years had increased at the rate of 20 million units per annum, compared with an increase of 12 million units per annum for the previous ten years.

The inefficiency from the engineering point of view is brought out by the statement that there are no less than 38 separate supply and traction undertakings in the 117 sq. miles, involving 48 power stations and 9 different frequencies of alternating current. Although reliability of supply is of the first importance and of far greater importance than the provision of a supply at a minimum cost, yet adequate safety could be secured with far less than the present number of power stations; and as most of the individual undertakings are being supplied by a single power station unconnected with any other undertaking, the general safety of supply would be improved if the separate undertakings were interconnected and supplied from a suitable number of modern power stations, each capable of dealing with demands of not less than 100,000 kw. A commencement, Mr.

Sparks suggests, could be made with one station to supplement the supply from existing stations, and as the less efficient of these passed gradually out of use, the main power station would be supplemented by a second or further stations as required.

Mr. Sparks then reviewed the improvements to which progress in electricity supply had been primarily due. Before the discovery of the 3-phase system by Galileo Ferraris and Nicola Tesla between 1885 and 1888, and its development by C. E. L. Brown and Dobrovolski, no transmission system was available capable of giving a general supply for all purposes. The economy in the first cost of 3-phase generators and transmission mains, and the ease of transformation of alternating currents by static transformers, combined with the invention of the induction motor, provided a system which enabled one undertaking to serve every class of demand in a large area. In the original alternating-current systems in this country, started for lighting supply, frequencies of 80 to 100 cycles per second were selected to keep down cost and to raise the efficiency. Although not recognised at the time, the choice of these high frequencies made the development of single-phase alternating-current motors almost impossible. Long before any general change took place in this country, low frequencies had been adopted by C. E. L. Brown in Switzerland for low-speed generators driven by water power, and by Ziperowski, who developed low-speed alternators direct-coupled to reciprocating engines. Although 50 cycles has now been adopted as the standard frequency of supply for all purposes outside special transmissions or single-phase railway work, the effect of developing alternating-current systems on a wrong basis has not yet been eradicated.

The theory of the parallel working of alternators was described by Mr. H. Wilde in 1868 and by Dr. Hopkinson in 1882 (following his tests on the parallel operation of de Merit's magneto machines, which were worked in parallel or run as synchronous motors), but the general parallel working of alternators was a matter of difficulty up to 1889, and was only seriously developed after the reading of Mr. W. M. Mordey's Paper on the subject before the Institution that year. Mr. Mordey had then also shown the possibility of converting single-phase alternating currents into continuous currents by the use of synchronised motor-generators.

The development of the steam turbine, due to Sir Charles Parsons, together with the adoption of superheated steam and suitable condensing facilities, had entirely changed the character of supply undertakings, by increasing the possible size of operating units, reducing the cost of generating and boiler-house plant and buildings, and lowering the operating cost. When an ample supply of cold condensing water is available, modern condensing plant is capable of maintaining a vacuum of 97 per cent. (29 to 30 in. vacuum) of the theoretical value in the turbine casing, as compared with the 25 to 30 in. vacuum (85 per cent.) normally used with reciprocating engines. The use of turbo-generators enables a watt-hour to be generated in large power stations supplying diversified demands for 20 to 25 B.Th.U. (say 1½ to 2 lb. of average coal per unit), as compared with 100 to 150 B.Th.U. (or 8 to 12 lb. of average coal per unit) originally used in the small stations using non-condensing reciprocating engines supplying lighting demands.

In the early days of the industry the average size of the generator in lighting stations was 100 kw., generators rated at 500 kw. being exceptional. The maximum size of turbo-generators is not yet in view; machines rated at 30,000 and 35,000 kw. and made by the General Electric Company (U.S.A.) are at work, while machines of still larger capacity are being designed. The upper limit in the size of generators is at present fixed by the extent of the system to be supplied and the limitations of the method of control, rather than by any limitations in design.

The main improvement in steam-raising is the universal use of large water-tube boilers, in which the superheater and economiser form an integral part, on normal output each boiler evaporating up to 50,000 lb. of steam per hour at 200 to 250 lb. per sq. in. pressure, the steam being superheated 200 to 250° F., as compared with boilers evaporating 8,000 to 10,000 lb. of steam at 80 to 150 lb. pressure.

Great progress has been made in furnace design and in mechanical stokers, thereby enabling small coal of comparatively low calorific value to be efficiently and smokelessly burnt. This has resulted in the average efficiency in conversion of the heat energy of the coal being raised from 65 to 85 per cent. on test and from 50 to 75 per cent. under operating conditions, with a material saving both in the cost of fuel and in labour. Instead of duplicate steam ranges of cast iron, with copper bends, single steel mains are used, while the continuous flow of steam required by turbines, as compared with the intermittent flow of steam with reciprocating engines, has further reduced the area of steam pipes exposed to condensation. The increase in size and the improved design of water-tube boilers and accessories have resulted in the space occupied by the boiler-house plant being reduced to one-fifth of that required for an equal evapo-

tion of steam 30 years ago. Through the introduction of turbo-driven machinery, which requires no internal lubricant, the durability of the boiler plant has been much improved.

The invention and development by Mr. Ferranti of the paper-insulated lead-covered cable not only reduced the cost of transmission and distribution, but has largely increased the reliability of operation.

No conversion of alternating current to continuous current by rotary converters was possible in the early stages owing to the want of an alternating-current motor. Rotary converters were first developed some 25 years ago in the United States for supplying traction systems, a frequency of 25 being standardised for transmission. It was not until 1905 that satisfactory 50-cycle rotary converters were developed. This was rendered possible by the introduction of interpoles, which allowed higher speeds to be used, thus securing reasonable spacing for commutation. The development of the 50-cycle rotary converter has resulted in reducing the space occupied by transforming plant to one-half of that required by motor-generators; the first cost has been reduced to between one-half and two-thirds, and the efficiency of conversion has been raised to 94 per cent. at full load.

Metering was a great difficulty in the case of early undertakings. The first meter developed for continuous-current supply was of the electrolytic type. No meters were available for alternating-current systems, and electricity was sold by annual contract. As an instance of close calibration and accuracy of present-day meters, Mr. Sparks gave the reading of three motor meters, the power factor of the supply varying from 0·8 to unity and the demand from 2·5 to 60 per cent. of the rated capacity of the meters.

| | Meter (1) | Meter (2) | Meter (3) |
|----------------------------|-----------|-----------|-----------|
| Number of units registered | 1,955,700 | 1,945,800 | 1,952,300 |
| Percentage error from mean | +0·23% | -0·28% | +0·05% |

The introduction of the metal filament lamp was, of course, one of the greatest advances. In addition to the 3-fold efficiency, another important result is that the lamp is much less sensitive to fluctuations in pressure. In the case of carbon filament lamps the statutory permissible voltage variation of 4 per cent. means that the light varied between -20 and +25 per cent. With the same pressure-variation and the metal-filament lamp the limits are -14 and +16 per cent. With the half-watt lamp, the variation is further reduced to 12 per cent. + or -.

The high efficiency of conversion from electric to mechanical power in the motor as originally developed left little room for improvement. The main efforts of designers have been devoted to reducing the weight and thus lowering the cost, which has fallen 50 per cent. in motors of moderate size during the last 15 years. The development of the induction motor, with its advantages of close speed-regulation and absence of commutation, has been largely responsible for electric driving being used in many industrial concerns in preference to other forms of power.

In the concluding part of his address, Mr. Sparks reviewed the direction in which further progress might be expected. He pointed out that the economical use of fuel has been hindered in this country by its low price, and that fuel is being used wastefully to the prejudice of future generations. Only a fraction of the total coal consumed is at present used for centralised source of supply of power and heat, the principal future economy in fuel is to be found in increasing this proportion. In the absence of any prospect of the development of an economical system of storage for electricity, which would at once raise the present load factors of from between 25 and 35 per cent. to nearly 100 per cent., and thus materially lower the cost of generation, or until some new method of converting the heat energy of coal to electricity is discovered, one of the next steps to lower the cost of production of electricity will be the gas-firing of boilers, the gas being obtained from producers worked at a low temperature. This will provide by-products from the distillation of the coal as a raw material for other industries. The sizes and positions of most of the present power stations prevent this system being used, as by-product processes can only be successfully worked on a large scale and with plant operating at a high load factor. It is also certain that electricity will prevail more and more as an illuminant owing to the greater number of candle-power-hours that can be obtained from a ton of coal by using electricity as compared with gas. With electricity generated in modern power-houses using a 25 B.Th.U. per watt-hour, and with 85 per cent. efficiency of distribution, the number of candle-power-hours obtained per ton of coal is with ordinary metal-filament lamps of 15 to 20 candle-power, no less than 750,000 as compared with 260,000 in the case of gas, gas mantles of 20 candle-power and 13,000 cubic feet of gas per ton of coal carbonised being assumed. Further research should result in improved dielectrics which would allow higher working pressures for underground cables, thus lowering the cost of transmission, increasing the size of each centralised undertaking, and again raising the operating load factor by the greater diversity in the demand.

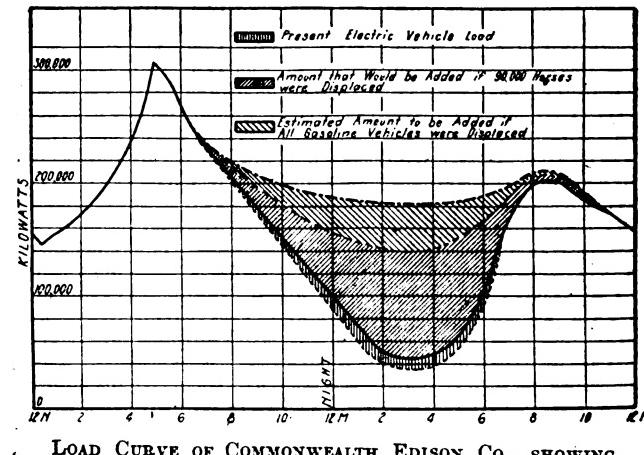

Pending this development, the economical radius of transmission can be increased by using overhead lines outside the thickly populated districts.

Lastly, Mr. Sparks referred briefly to electric cooking and heating. While on the one hand it is only possible to deliver to consumers some 15 per cent. of the heat energy in the coal, regard must be had to the low-efficiency when coal or gas is burnt direct, owing to the necessity of getting rid of the products of combustion. This low efficiency allows electricity to compete successfully for all intermittent uses. The present cost of the apparatus and its maintenance should be reduced by a large expansion of business, as soon as the supply undertakings are prepared to let on hire and maintain apparatus on liberal terms in the same manner as the electric motor business was developed. Low price per unit is also justified for this class of supply by the high diversity factor and the large number of hours of use, resulting in a greatly improved load factor from the residential demand.

EFFECT OF ELECTRIC VEHICLE CHARGING ON THE LOAD CURVE

At a recent convention of the Indiana Electric Light Association Mr. Q. A. Brackett read an interesting Paper on the characteristics of the battery-charging load of electric vehicles. Much has already been done towards increasing the off-peak day load by pushing the sale of electric heating and cooking appliances and the development of the motor load, but much remains to be done in filling in the light load period between midnight and morning. For this there is nothing so well suited as the charging of storage batteries; it can be made to fill up the worst hollow in the load curve during the small hours of the morning; it is a long-continued load, not a fifteen-minute one like cooking devices; it should become a regularly recurring load and frequent, occurring practically every night; it is a comparatively heavy load, usually many times greater than the average lighting load; and it is a steady load of good power-factor, and is not subject to sudden changes like a motor load.

Mr. Brackett emphasised that the first thing that a central station must do to increase the use of electric vehicles in its territory is to make special rates for power when used for

LOAD CURVE OF COMMONWEALTH EDISON CO., SHOWING IMPORTANCE OF BATTERY-CHARGING LOAD.

off-peak charging, and advertise this fact conspicuously. The second step should be to educate the public as to the advantages of the electric vehicle and its real economy over other types by continuing the policy now being adopted by central station electrical vehicle enthusiasts in this country by using these vehicles themselves and securing their adoption by other municipal departments.

For a number of years, said Mr. Brackett, a commercial electric vehicle has always meant a fairly large and expensive chassis, which only large concerns dealing in heavy merchandise would buy. Lately, however, light electric delivery vans, costing below £200, have appeared on the market, and these open up a new field for the application of electric vans to the delivery service of bakeries, grocery and provision stores, light express services, &c., where the one-horse van is so common to-day.

The author showed a load curve, which we reproduce. It represents graphically the vast improvement capable of being effected to the load of a central station by the addition of battery charging for electric vehicles, and incidentally also the limited progress that has so far been made by the Company in question. It must not be forgotten, however, that our municipal electricity works should have considerable advantage over a company in being able to bring about more readily the utilisation of electric cars in the other departments of the Corporation, which, as has already been mentioned, is the best advertisement to the public.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 18th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

16,850/14. **Incandescent Lamps.** H. G. FINCH (LORD GUERNSEY) and J. F. POYNTER. Metal filament lamps with helically-coiled filaments arranged in star form on a series of supports, those at the inner angles of the star being in a plane nearer the neck of the lamp than those at the points. (Two figures.)

24,419/14. **Insulating Compound.** B. T.-H. Co. (G.E. Co., U.S.A.). A moulded compound made by thickening china wood oil mixed with asbestos fibre, ground marble, and carbon black by heating.

4,776/15. **Carbon Filaments.** SIEMENS & HALSKE A.G. Filaments or rods composed mainly of graphitised carbon are made by depositing carbon on a tungsten core, heating in an electric furnace to a temperature equal to or above the melting point of tungsten, and subjecting to high pressures. (One figure.)

8,173/15. **Vapour Rectifiers.** BRITISH WESTINGHOUSE Co. A vapour rectifier system for converting A.C. to D.C. for traction, in which several rectifier units are grouped in conjunction with tappings on a transformer with suitable switchgear to enable a variable voltage to be obtained. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

DYNAMOS, MOTORS, AND TRANSFORMERS: ROUTIN [A.C. motor group control] 4,079/14.

Instruments and Meters: LINCOLN [Thermal meters] 21,792/14; HOLDEN [Moving coil instruments] 23,071/14; BOOTH and MILLER [Prepayment meters] 937/15.

Switchgear, Fuses, and Fittings: B. T.-H. Co. (G.E. Co., U.S.A.) [Electromagnetic switches] 23,544/14.

Telephony and Telegraphy: SHEPPARD and McKECHNIE [Line or wireless telegraphy] 20,319/14; BRITISH INSULATED & HELSBY CABLES, LTD., FULLER and HARRISON [Duplex telephony] 22,554/14; GREENWOOD [Telephone receivers] 22,887/14; PARKER [Telegraph wire joint] 757/15.

Traction: MIDGLEY and VANDERVELL [Electric engine starters] 23,357/14; ÖSTERREICHISCHE DAIMLER-MOTOREN A.G., 9,682/15.

Miscellaneous: RICCI and RICCI [Portable head lamps] 1,689/15; F. BARKER & SON, LTD., and BARKER [Magnetic compasses] 1,818/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Switchgear, &c.: SOC. GÉNÉRALE DE CONDENSATEURS ÉLECTRIQUES [Excess voltage protection] 15,148/15; GILES [Excess voltage protection] 15,196/15.

Opposition to Grant of Patent

A grant of a patent has been allowed on the following application in spite of opposition:—

6,900/13. DORMER. Relays for automatic signalling actuated by superposed A.C. and D.C.

The following are the more important Patents that have become void through non-payment of renewal fees.

DYNAMOS, MOTORS, AND TRANSFORMERS: V. LOWENDAHL [Brushes] 17,002/02; DEUTSCHE-ELECTRISCHE SPARLICHT GES. [Reducing transformers] 17,761/09.

Electrochemistry and Electrometallurgy: AKTIEBOLAGET ELEKTROMETALL [Electric furnaces] 17,342/09.

Incandescent Lamps: D. ASSERSONH [Tubular lamps, reflectors, &c., for strip lighting] 17,855/07.

Switchgear, Fuses, and Fittings: L. M. WATERHOUSE [Resistances] 17,196/02.

Miscellaneous: D. MAGGIORA and J. M. SINCLAIR [Electrically-driven gramophones] 17,864/09; M. KAROLYI and C. BERGER [Electrical control apparatus actuated by sound waves] 17,932/09; SIEMENS BROTHERS & CO., LTD. [Electric clocks] 18,005/09.

DESIGN OF HIGH-SPEED GENERATORS

At the Institution of Electrical Engineers in Birmingham last night Prof. A. B. Field read a Paper on "Some Difficulties of Design of High-Speed Generators." The Paper will be read in London to-night.

The author based his remarks chiefly on the example afforded by a particular machine—a turbo-generator of 20,000 k.v.a., 3-phase, 4-pole, 60-cycle, 13,200 volts, with a rotor measuring 51 inches by 75 inches. He pointed out first that there was the problem of constructing a rotor weighing about 60,000 lbs., and with a peripheral speed of 24,000 ft. per minute, the centrifugal force on a 1 lb. mass at the periphery being about 1 ton.

In discussing the method and material of rotor construction, it was shown that the nature of the stresses in turbo-rotors is different to that occurring in similar forgings for general engineering purposes. In the former there are large radial stresses reaching down to the centre, whereas in the latter the stresses are chiefly longitudinal and near the surface. To meet these difficulties in the case of large, high-speed, waterwheel-driven generators, one firm had used open-hearth rolled plates consolidated and mounted on a shaft. Compared with rolled plates there is probably no other form in which such large masses of steel can be produced at a low cost having such good physical properties in directions of two dimensions. The impossibility of using a central shaft, however, for the largest turbo-rotors, introduced a serious difficulty, and it was due to the suggestion of Behrend that the feasibility was demonstrated of constructing such a rotor with the plates slightly rabbeted into one another, and into a flanged shaft at each end. With this construction, with 4 or 6 chrome-nickel steel bolts each of 4 inches diameter, a 50- to 56-inch diameter rotor can be constructed with practically the solidity of a single piece.

The question of critical speed was next discussed. It is believed to be an advantage to keep the critical speed above the running speed when this is feasible, and this considera-

tion affects the proportions of the whole machine. The rotor body has to be short, which means a high gap density and severe working of the stator material in the neighbourhood of the gap. The shaft diameter must be large, hence high peripheral speeds must be tolerated for journals and slip-rings.

On the subject of ventilation of rotors, the author stated that it is extraordinary how large a rotor loss can be dissipated merely from the drum surface with no ventilation, and that it is commonplace knowledge how little good some fairly elaborate ventilation systems are found to do. He described in detail a simple and effective system of ventilation to which the plate construction of rotor specially lends itself. It consists essentially of axial vents beneath the slots, with radial discharge openings cut out between the plates before the latter are assembled.

The matter of the support of the rotor windings against centrifugal forces, and forces caused by short circuits, was entered into. For the support of the slot portion of the winding, special wedges were described, and the question of retaining rings for the support of the end-connections was discussed at considerable length. In rotors of this size mechanical considerations must take precedence over everything else, hence weldless chrome-nickel steel is used for these end-rings, in spite of magnetic difficulties being introduced.

Although the construction of rotors forms the main theme of the Paper, the subject of stator construction was also treated at some length. The arrangements for stator ventilation and mechanical support of the windings to stand severe short circuits were discussed. With regard to the latter the author said that it was now considered necessary to build these large machines so that they could be dead short-circuited at their terminals when running excited and giving full voltage.

The Paper was concluded with a description of a special type of "magnetic wedges" which were inserted in large stator slots, to overcome the difficulty encountered of considerable rotor face losses occasioned by large open stator slots and comparatively small air-gaps.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,470.

We have occasion to make good welded joints in copper wires of all sizes, from the smallest up to $\frac{1}{8}$ in. square. Would a "welding transformer" be suitable for this? If so, what is the arrangement made for adjusting the current to the right value for various sizes of wire?

(Replies must be received not later than first post,
Thursday, Dec. 2nd.)

ANSWERS TO No. 1,468.

I have a D.C. motor rated at 20 h.p., 950 r.p.m., which drives some line shafting for machine tools. It is a 220-volt, 4-pole, shunt machine, with lap-wound armature, and has good commutation. I wish to increase the normal speed to 1,100 r.p.m. for special work during the war, and then to reduce it again to its normal value. What is the most economical way of doing this?

The first award (10s.) is given to "Alpha" for the following reply:—

There are two ways in which the speed of a shunt-wound motor can be readily increased:—

(1) By increasing the air-gap between pole face and armature.

(2) By reducing the field current.

I suggest that in the present case the inquirer should first slack off the bolts holding one of the main poles in the frame, and see whether there are any thin iron shims behind the pole. If so, these should be removed from behind all the poles, and the bolts tightened up again. If this increases the speed of the motor too much, thinner shims of soft sheet-iron should be substituted for those taken out. Assuming normal values for the air-gap length and the saturation curve of the motor in question, it is probable that an increase in the length of the air-gap of about $1/32$ " will give somewhere near the required speed. It is impossible to give more definite figures without full particulars of the design of the motor, but if there are shims behind the poles the matter can easily be settled by experiment as described above. The shims taken out can be kept and replaced when the motor speed is required to be reduced to 950 r.p.m. again. The cost of this method would only be the man's time in removing the shims.

If there are no shims behind the poles, it would be possible to increase the gap by grinding back the pole faces or by increasing the bore of the frame, but it would be simpler and cheaper in this case to reduce the field current by connecting a resistance in series with the shunt winding. The makers of the motor would doubtless supply a suitable resistance, all they would require to know being the particulars given on the name-plate (particularly the serial number of the motor) and the amount of speed increase required. If for any reason they cannot be communicated with, an ammeter and a variable resistance should be connected in the shunt-field circuit, the resistance being variable from 0 to, say, 150 ohms, with a current capacity of about 2 amps. The particulars required are the terminal voltage, the shunt-field current taken by the machine with no resistance in circuit, and the shunt-field current, with such value of resistance as

will give the required speed. The test should preferably be taken with the motor warm, i.e., after not less than three hours' run on normal load, and could be carried out in a few minutes by any competent local electrician. From the figures obtained any manufacturer of electrical control gear could make up a suitable resistance unit. No sliding contacts or switch would be necessary, the resistance being merely connected in the field circuit and left there until it is desired to reduce the motor speed to 950 r.p.m., when it can be disconnected. The cost of the resistance would be about 10s. or 15s., to which would be added the man's time in making the necessary test and connecting up the resistance.

As the commutation of the motor is good under present conditions, it is not likely that it would be materially affected by the proposed increase in speed if the machine has commutating poles. If not, it is possible that the operation would be impaired, since the h.p. will presumably be increased at least in proportion to the speed. If it is, the brushes can be given a little more backward lead, and this will probably put matters right. It should not be necessary to adjust the brush position if the motor has commutating poles, but the effect of a small movement forward or backward may be tried if the operation is bad. The best position with commutating poles will be found to be on the neutral point.

The second award (5s.) is made to "E. H." for the following reply:—

The two methods of increasing the speed of a shunt motor are either to increase the length of the air-gap or to increase the resistance of the shunt circuit, the effect in both cases being to decrease the flux. The increased air-gap is generally obtained by taking out the "liners," or thin sheets of iron, that are placed at the back of the pole-cores or of the pole-shoes; but the thickness of these sheets is exceedingly seldom sufficient to give the 16 per cent. speed variation required in the question. Since the commutation at the present speed appears to be good, it will be simpler and more economical to get the whole of the speed variation by decreasing the shunt current. A rough approximation of the value of the extra resistance can be found thus:—

The normal loss in the shunt winding of a 20 h.p. 950 r.p.m. protected type motor is about 500 watts, so that the corresponding shunt current is 2.3 amperes. The magnetisation curve for the machine is not given, but taking values off a typical curve for such a motor, the shunt current must be decreased to about 0.73 of its normal value in order to decrease the flux sufficiently to give 16 per cent. increase of speed. Hence the shunt current at 1,100 r.p.m. is $0.73 \times 2.3 = 1.68$ amps.

The resistance of the shunt circuit for 950 r.p.m. is about $\frac{220}{2.3} = 95.6$ ohms, and the new resistance is $\frac{220}{1.68} = 131$ ohms, so that the resistance of the shunt circuit must be increased by 35.4 ohms. The writer would therefore suggest that a resistance of about 40 ohms capable of carrying 3 amperes (this being approximately the current when the machine is cold) should be connected in series with the shunt winding. Should this be a little too much, it is an easy matter to cut some of it out. When the speed is to be reduced to its original value, all that need be done is to remove or short-circuit the extra resistance.

Injunction against Electricity Works for Nuisance.—In the Chancery Division on Friday, Mr. Justice Neville granted an injunction against the Aldershot Urban District Council to restrain them from so running and working their electrical plant as to cause a nuisance. The injunction, however, is only to come into effect three months after the declaration of peace. The application was made by a Mrs. Dexter, who occupies a house about 70 yards distant from the station, and takes in paying guests. Evidence was given to the effect that there was considerable noise and vibration from a Diesel engine, and it was alleged that the spray driven over from a cooling tower was also objectionable. In delivering judgment, Mr. Justice Neville said that the evidence on behalf of the plaintiff had been free from the exaggeration which usually was a feature of such cases, and he had come to the conclusion that the noise and vibration did amount to an actionable nuisance, but that the nuisance arising from the cooling tower was very slight. The cooling tower is 65 ft. high—20 ft. higher than the ridge of the plaintiff's house. An offer to pay the plaintiff £5 to defray her costs, and to undertake not to use the Diesel engine, except during peak load, had been refused.

THE ELECTRICAL INDUSTRY AFTER THE WAR

M R. D. A. STARR, in his Chairman's address to the Scottish Local Section of the Institution of Electrical Engineers on November 9th, first made reference to the death of Captain E. George Tidd, who for many years had been connected with the Section as Honorary Secretary and afterwards as Chairman. Captain Tidd was killed in action in the Dardanelles.

The greater portion of the address was a review of the multifarious applications of electricity in all spheres of action in the war, but towards the end Mr. Starr went into a little detail as to how the electrical industry as a whole is going to be affected when the war is over. It is, he said, very difficult to forecast what may happen, but a few points which occurred to him might be worthy of consideration. It was almost certain that there would be a reduction in the supply of electrical energy required for munition work, many power contracts having been made for the duration of the war only. It would take some time to re-organise industrial works temporarily equipped for this class of work, and to restore the plant to normal industrial capacity. On the other hand, it was quite possible that a great many manufacturers will find new markets for their products both at home and abroad. During the war our shipyards have been almost invariably engaged on war material. A great many ships have been rendered useless for their original purposes through being stripped of their fittings and converted into armed cruisers, transports, &c. The shortage of merchant ships consequent on German submarine activities must to some extent be made up, and it was therefore reasonable to expect that ship-builders and a great many engineering concerns dependent on the subsidiary work in connection both with naval and mercantile shipbuilding and ship repairing would be exceedingly busy. The restrictions placed on the export of coal would be withdrawn, and the output of the collieries should be consequently increased.

Opportunities, too, would be afforded to British manufacturers to obtain a firm footing in markets all over the world, which hitherto have been entirely in the hands of the Germans, and if these opportunities were grasped an increase in the number of industrial factories might be looked for. Naturally, money to finance new projects would be both scarce and dear, but making allowances for these we should be in a better position than our enemies or allies. This was a subject which should engage the most thorough consideration and attention of the personnel of the electrical industry in common with that of other British manufacturers.

Another matter which Mr. Starr dealt with to some extent was the cost of production, in which the two items entering very largely were, he said, coal and labour. He drew attention to the fact that the present prices of coal, compared with 1911 and 1912, show an increase of nearly 100 per cent., as far as the West of Scotland is concerned, and looked at from the power producers' point of view the remedy was to have a coal clause in all contracts with consumers. As regards labour, he strongly condemned the agitation which has been going on since the war started for increased wages, and he felt sure that all true patriots would have welcomed, either at the time war was declared or shortly afterwards, a Royal Proclamation putting every man, woman, and child in the country under martial law.

The Western Electric Co. Fined.—At the Woolwich Police Court on Friday the hearing was concluded of several summonses against the Western Electric Co., Ltd., for sending by post some small parcels of telephonic apparatus, being prohibited exports, to Norway on various dates from January to June this year. The fines and costs amounted to £54 12s., the magistrate remarking that the offences had evidently been caused by gross carelessness on the part of certain members of the staff, there being no intention that the goods should reach the enemy. It was explained during the proceedings that the Company undertook to complete certain contracts for the Bell Telephone Co. of Antwerp after the German occupation, and the latter company's staff and manager came to England in this connection. It appeared that the manager, who was also fined, sent the parcels in question by post to avoid the delay of getting the licences which are necessary when goods are sent from the docks.

Suspension of Sec. 27 of Patents Act.—A Bill has been introduced into the House of Commons by the Government suspending during the continuance of the present war and for six months thereafter Section 27 of the Patents Act of 1907. This section is the one compelling a patentee to work his patent within the United Kingdom, and enables a person to apply for revocation on the ground that the patented article is manufactured or carried on exclusively or mainly outside the United Kingdom.

DESIGN OF POWER STATION SWITCHBOARDS

M R. P. V. HUNTER'S address on November 8th as Chairman of the Newcastle Section of the Institution of Electrical Engineers was devoted to a general discussion of the design of power-station switchboards and arrangement of switchgear.

A number of diagrams of bus-bar connections in power stations were exhibited with the object of showing the difference in the extent to which they provide against internal breakdown of the switchboard. He demonstrated that multiplication of parts, designed to provide against breakdown, may actually prove conducive to breakdown, and considered that in general it would be preferable to spend money on apparatus having larger provision against accident, than in resorting to a more complicated arrangement.

He then entered into a discussion of the more common kinds of trouble met with in switchgear, referring to mistakes of staff, such as opening the isolator of a feeder carrying load instead of the one next to it; unforeseen effects, as, for instance, the abnormal mechanical forces occurring on short circuits; and weakness or deterioration of apparatus, this, however, being of rare occurrence. He considered that perhaps undue faith had been placed on the use of reactances for meeting severe conditions, and that the possibility of oil-switches for opening even heavy short-circuits had been overlooked.

In conclusion, the Chairman said that experience led him to the view that it would be a mistake to attempt to standardise switchboard arrangements or switches.

HOW TO KEEP STORAGE BATTERIES "FIT"

A THOROUGHLY practical Paper on storage batteries was read before the Association of Supervising Electricians by Mr. R. Rankin on Tuesday, Nov. 2nd. In the choice of a battery, he said, the most important point is to get it large enough. Having got the large battery, there are important things to remember in connection with the first charge. A continuous 24-hour run is essential for this, and it does not do, therefore, to make this charge the first trial of the generating plant. The latter should be well tested before the cells are filled with acid; then they should be filled and the charge started as soon as this is completed. The initial specific gravity of the acid is usually about 1.200 at normal temperature. In giving the first charge, only about two-thirds the normal charge rate should be followed, which is, in general, roughly equal to the 7-hour discharge rate. During this charge the temperature of the cells should be observed, and if it rises above 100° F., the charging current should be reduced to keep the temperature below this value. The specific gravity will first drop and then rise, and the voltage, of course, will gradually rise, and charging should be continued until there is no increase in either for about six hours. It is wrong to assume that the first charge is complete when a certain voltage or specific gravity is reached, or when the plates assume a good colour, or when they are gassing freely, or merely after a definite number of hours. With regard to constancy of specific gravity, however, it may be noted that if the temperature is rising, the specific gravity may decrease. A correction of one point for every 3° F. above 60° F. may be applied.

As soon as the first charge is completed the battery may be put into commission, but it will usually be necessary first to adjust the specific gravity of some cells and level of the electrolyte in all the cells, and at first also a generous amount of excess charge should be given after each discharge.

The Paper contains the following useful table, giving the relative capacities, corresponding currents, and final voltages at different discharge rates:—

| Duration of discharge (hours). | Capacity in terms of maximum | Rate of discharge in terms of 10-hour rate. | Final P.D. (volts.) |
|--------------------------------|------------------------------|---|---------------------|
| 10 | 1.00 | 1.00 | 1.83 |
| 9 | .98 | 1.09 | 1.83 |
| 8 | .95 | 1.19 | 1.83 |
| 7 | .92 | 1.31 | 1.83 |
| 6 | .88 | 1.46 | 1.83 |
| 5 | .83 | 1.67 | 1.83 |
| 4 | .78 | 1.95 | 1.80 |
| 3 | .72 | 2.39 | 1.80 |
| 2 | .63 | 3.17 | 1.78 |
| 1 | .50 | 5.00 | 1.75 |
| .75 | .45 | 5.84 | 1.70 |
| .5 | .37 | 7.45 | 1.70 |
| .25 | .22 | 8.95 | 1.70 |
| Peak | | 12.50 | 1.60 |

Users of batteries are warned of the danger of deciding when the battery is sufficiently discharged merely by the

Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,470.

We have occasion to make good welded joints in copper wires of all sizes, from the smallest up to $\frac{1}{8}$ in. square. Would a "welding transformer" be suitable for this? If so, what is the arrangement made for adjusting the current to the right value for various sizes of wire?

(Replies must be received not later than first post,
Thursday, Dec. 2nd.)

ANSWERS TO No. 1,468.

I have a D.C. motor rated at 20 h.p., 950 r.p.m., which drives some line shafting for machine tools. It is a 220-volt, 4-pole, shunt machine, with lap-wound armature, and has good commutation. I wish to increase the normal speed to 1,100 r.p.m. for special work during the war, and then to reduce it again to its normal value. What is the most economical way of doing this?

The first award (10s.) is given to "Alpha" for the following reply:—

There are two ways in which the speed of a shunt-wound motor can be readily increased:—

(1) By increasing the air-gap between pole face and armature.

(2) By reducing the field current.

I suggest that in the present case the inquirer should first slack off the bolts holding one of the main poles in the frame, and see whether there are any thin iron shims behind the pole. If so, these should be removed from behind all the poles, and the bolts tightened up again. If this increases the speed of the motor too much, thinner shims of soft sheet iron should be substituted for those taken out. Assuming normal values for the air-gap length and the saturation curve of the motor in question, it is probable that an increase in the length of the air-gap of about $1/32$ " will give somewhere near the required speed. It is impossible to give more definite figures without full particulars of the design of the motor, but if there are shims behind the poles the matter can easily be settled by experiment as described above. The shims taken out can be kept and replaced when the motor speed is required to be reduced to 950 r.p.m. again. The cost of this method would only be the man's time in removing the shims.

If there are no shims behind the poles, it would be possible to increase the gap by grinding back the pole faces or by increasing the bore of the frame, but it would be simpler and cheaper in this case to reduce the field current by connecting a resistance in series with the shunt winding. The makers of the motor would doubtless supply a suitable resistance, all they would require to know being the particulars given on the name-plate (particularly the serial number of the motor) and the amount of speed increase required. If for any reason they cannot be communicated with, an ammeter and a variable resistance should be connected in the shunt-field circuit, the resistance being variable from 0 to, say, 150 ohms, with a current capacity of about 2 amps. The particulars required are the terminal voltage, the shunt-field current taken by the machine with no resistance in circuit, and the shunt-field current, with such value of resistance as

will give the required speed. The test should preferably be taken with the motor warm, i.e., after not less than three hours' run on normal load, and could be carried out in a few minutes by any competent local electrician. From the figures obtained any manufacturer of electrical control gear could make up a suitable resistance unit. No sliding contacts or switch would be necessary, the resistance being merely connected in the field circuit and left there until it is desired to reduce the motor speed to 950 r.p.m., when it can be disconnected. The cost of the resistance would be about 10s. or 15s., to which would be added the man's time in making the necessary test and connecting up the resistance.

As the commutation of the motor is good under present conditions, it is not likely that it would be materially affected by the proposed increase in speed if the machine has commutating poles. If not, it is possible that the operation would be impaired, since the h.p. will presumably be increased at least in proportion to the speed. If it is, the brushes can be given a little more backward lead, and this will probably put matters right. It should not be necessary to adjust the brush position if the motor has commutating poles, but the effect of a small movement forward or backward may be tried if the operation is bad. The best position with commutating poles will be found to be on the neutral point.

The second award (5s.) is made to "E. H." for the following reply:—

The two methods of increasing the speed of a shunt motor are either to increase the length of the air-gap or to increase the resistance of the shunt circuit, the effect in both cases being to decrease the flux. The increased air-gap is generally obtained by taking out the "liners," or thin sheets of iron that are placed at the back of the pole-cores or of the pole-shoes; but the thickness of these sheets is exceedingly seldom sufficient to give the 16 per cent. speed variation required in the question. Since the commutation at the present speed appears to be good, it will be simpler and more economical to get the whole of the speed variation by decreasing the shunt current. A rough approximation of the value of the extra resistance can be found thus:—

The normal loss in the shunt winding of a 20 h.p. 950 r.p.m. protected type motor is about 500 watts, so that the corresponding shunt current is 2.3 amperes. The magnetisation curve for the machine is not given, but taking values off a typical curve for such a motor, the shunt current must be decreased to about 0.73 of its normal value in order to decrease the flux sufficiently to give 16 per cent. increase of speed. Hence the shunt current at 1,100 r.p.m. is $0.73 \times 2.3 = 1.68$ amps.

The resistance of the shunt circuit for 950 r.p.m. is about $220 / 2.3 = 95.6$ ohms, and the new resistance is $220 / 1.68 = 131$ ohms, so that the resistance of the shunt circuit must be increased by 35.4 ohms. The writer would therefore suggest that a resistance of about 40 ohms capable of carrying 3 amperes (this being approximately the current when the machine is cold) should be connected in series with the shunt winding. Should this be a little too much, it is an easy matter to cut some of it out. When the speed is to be reduced to its original value, all that need be done is to remove or short-circuit the extra resistance.

Injunction against Electricity Works for Nuisance.—In the Chancery Division on Friday, Mr. Justice Neville granted an injunction against the Aldershot Urban District Council to restrain them from so running and working their electrical plant as to cause a nuisance. The injunction, however, is only to come into effect three months after the declaration of peace. The application was made by a Mrs. Dexter, who occupies a house about 70 yards distant from the station, and takes in paying guests. Evidence was given to the effect that there was considerable noise and vibration from a Diesel engine, and it was alleged that the spray driven over from cooling tower was also objectionable. In delivering judgment, Mr. Justice Neville said that the evidence on behalf of the plaintiff had been free from the exaggeration which usually was a feature of such cases, and he had come to the conclusion that the noise and vibration did amount to an actionable nuisance, but that the nuisance arising from the cooling tower was very slight. The cooling tower is 65 ft. high—20 ft. higher than the ridge of the plaintiff's house. An offer to pay the plaintiff £5 to defray her costs, and to undertake not to use the Diesel engine, except during peak load, had been refused.

THE ELECTRICAL INDUSTRY AFTER THE WAR

M R. D. A. STARR, in his Chairman's address to the Scottish Local Section of the Institution of Electrical Engineers on November 9th, first made reference to the death of Captain E. George Tidd, who for many years had been connected with the Section as Honorary Secretary and afterwards as Chairman. Captain Tidd was killed in action in the Dardanelles.

The greater portion of the address was a review of the multifarious applications of electricity in all spheres of action in the war, but towards the end Mr. Starr went into a little detail as to how the electrical industry as a whole is going to be affected when the war is over. It is, he said, very difficult to forecast what may happen, but a few points which occurred to him might be worthy of consideration. It was almost certain that there would be a reduction in the supply of electrical energy required for munition work, many power contracts having been made for the duration of the war only. It would take some time to re-organise industrial works temporarily equipped for this class of work, and to restore the plant to normal industrial capacity. On the other hand, it was quite possible that a great many manufacturers will find new markets for their products both at home and abroad. During the war our shipyards have been almost invariably engaged on war material. A great many ships have been rendered useless for their original purposes through being stripped of their fittings and converted into armed cruisers, transports, &c. The shortage of merchant ships consequent on German submarine activities must to some extent be made up, and it was therefore reasonable to expect that ship-builders and a great many engineering concerns dependent on the subsidiary work in connection both with naval and mercantile shipbuilding and ship repairing would be exceedingly busy. The restrictions placed on the export of coal would be withdrawn, and the output of the collieries should be consequently increased.

Opportunities, too, would be afforded to British manufacturers to obtain a firm footing in markets all over the world, which hitherto have been entirely in the hands of the Germans, and if these opportunities were grasped an increase in the number of industrial factories might be looked for. Naturally, money to finance new projects would be both scarce and dear, but making allowances for these we should be in a better position than our enemies or allies. This was a subject which should engage the most thorough consideration and attention of the personnel of the electrical industry in common with that of other British manufacturers.

Another matter which Mr. Starr dealt with to some extent was the cost of production, in which the two items entering very largely were, he said, coal and labour. He drew attention to the fact that the present prices of coal, compared with 1911 and 1912, show an increase of nearly 100 per cent., as far as the West of Scotland is concerned, and looked at from the power producers' point of view the remedy was to have a coal clause in all contracts with consumers. As regards labour, he strongly condemned the agitation which has been going on since the war started for increased wages, and he felt sure that all true patriots would have welcomed, either at the time war was declared or shortly afterwards, a Royal Proclamation putting every man, woman, and child in the country under martial law.

The Western Electric Co. Fined.—At the Woolwich Police Court on Friday the hearing was concluded of several summonses against the Western Electric Co., Ltd., for sending by post some small parcels of telephonic apparatus, being prohibited exports, to Norway on various dates from January to June this year. The fines and costs amounted to £54 12s., the magistrate remarking that the offences had evidently been caused by gross carelessness on the part of certain members of the staff, there being no intention that the goods should reach the enemy. It was explained during the proceedings that the Company undertook to complete certain contracts for the Bell Telephone Co. of Antwerp after the German occupation, and the latter company's staff and manager came to England in this connection. It appeared that the manager, who was also fined, sent the parcels in question by post to avoid the delay of getting the licences which are necessary when goods are sent from the docks.

Suspension of Sec. 27 of Patents Act.—A Bill has been introduced into the House of Commons by the Government suspending during the continuance of the present war and for six months thereafter Section 27 of the Patents Act of 1907. This section is the one compelling a patentee to work his patent within the United Kingdom, and enables a person to apply for revocation on the ground that the patented article is manufactured or carried on exclusively or mainly outside the United Kingdom.

DESIGN OF POWER STATION SWITCHBOARDS

M R. P. V. HUNTER'S address on November 8th as Chairman of the Newcastle Section of the Institution of Electrical Engineers was devoted to a general discussion of the design of power-station switchboards and arrangement of switchgear.

A number of diagrams of bus-bar connections in power stations were exhibited with the object of showing the difference in the extent to which they provide against internal breakdown of the switchboard. He demonstrated that multiplication of parts, designed to provide against breakdown, may actually prove conducive to breakdown, and considered that in general it would be preferable to spend money on apparatus having larger provision against accident, than in resorting to a more complicated arrangement.

He then entered into a discussion of the more common kinds of trouble met with in switchgear, referring to mistakes of staff, such as opening the isolator of a feeder carrying load instead of the one next to it; unforeseen effects, as, for instance, the abnormal mechanical forces occurring on short circuits; and weakness or deterioration of apparatus, this, however, being of rare occurrence. He considered that perhaps undue faith had been placed on the use of reactances for meeting severe conditions, and that the possibility of oil-switches for opening even heavy short-circuits had been overlooked.

In conclusion, the Chairman said that experience led him to the view that it would be a mistake to attempt to standardise switchboard arrangements or switches.

HOW TO KEEP STORAGE BATTERIES "FIT"

A THOROUGHLY practical Paper on storage batteries was read before the Association of Supervising Electricians by Mr. R. Rankin on Tuesday, Nov. 2nd. In the choice of a battery, he said, the most important point is to get it large enough. Having got the large battery, there are important things to remember in connection with the first charge. A continuous 24-hour run is essential for this, and it does not do, therefore, to make this charge the first trial of the generating plant. The latter should be well tested before the cells are filled with acid; then they should be filled and the charge started as soon as this is completed. The initial specific gravity of the acid is usually about 1·200 at normal temperature. In giving the first charge, only about two-thirds the normal charge rate should be followed, which is, in general, roughly equal to the 7-hour discharge rate. During this charge the temperature of the cells should be observed, and if it rises above 100° F., the charging current should be reduced to keep the temperature below this value. The specific gravity will first drop and then rise, and the voltage, of course, will gradually rise, and charging should be continued until there is no increase in either for about six hours. It is wrong to assume that the first charge is complete when a certain voltage or specific gravity is reached, or when the plates assume a good colour, or when they are gassing freely, or merely after a definite number of hours. With regard to constancy of specific gravity, however, it may be noted that if the temperature is rising, the specific gravity may decrease. A correction of one point for every 3° F. above 60° F. may be applied.

As soon as the first charge is completed the battery may be put into commission, but it will usually be necessary first to adjust the specific gravity of some cells and level of the electrolyte in all the cells, and at first also a generous amount of excess charge should be given after each discharge.

The Paper contains the following useful table, giving the relative capacities, corresponding currents, and final voltages at different discharge rates:—

| Duration of discharge (hours). | Capacity in terms of maximum | Rate of discharge in terms of 10-hour rate. | Final P. 11 (volts.) |
|--------------------------------|------------------------------|---|----------------------|
| 10 | 1·00 | 1·00 | 1·83 |
| 9 | .98 | 1·09 | 1·83 |
| 8 | .95 | 1·19 | 1·83 |
| 7 | .92 | 1·31 | 1·83 |
| 6 | .88 | 1·46 | 1·83 |
| 5 | .83 | 1·67 | 1·83 |
| 4 | .78 | 1·95 | 1·80 |
| 3 | .72 | 2·39 | 1·80 |
| 2 | .63 | 3·17 | 1·78 |
| 1 | .50 | 5·00 | 1·75 |
| .75 | .45 | 5·84 | 1·70 |
| .5 | .37 | 7·45 | 1·70 |
| .25 | .22 | 8·95 | 1·70 |
| Peak | | 12·50 | 1·60 |

Users of batteries are warned of the danger of deciding when the battery is sufficiently discharged merely by the

switchboard voltmeter reading. Instruments are liable to error, and if the voltmeter is reading high, it may happen that the battery is over-discharged on every occasion.

A fact not so well known as it should be is that a cell must not be charged at very low rates, and the attendant should ascertain the minimum charging current from the makers. If charged below this rate the negative plates will be charged, but the positive plates merely sulphated instead of being charged. For this reason "milking" boosters must always be capable of charging at full normal charging current.

On the other hand, charging at too high a rate is also bad; it results in violent gassing long before the charge is completed, and consequently loosening the active material on the positives, which means loss of capacity, and therefore leads to subsequent over-discharge, and the effect will thus be cumulative.

A common error is to assume that if the charge in ampere-hours is 10 per cent. above the discharge, everything is right. But 90 per cent. ampere-hour efficiency may be regarded as the limit, and this means that the charge should at any rate be one-ninth and not merely a tenth more than the previous discharge, even if the very best charging rate is hit upon.

Practically every one of the mistakes mentioned will eventually lead to the cell getting badly sulphated, and when in this condition it exhibits the misleading characteristic of gassing freely long before the charge is completed; this is particularly deceptive, as a high voltage accompanies this phenomenon. With a cell in this condition, if the charge is further continued, the milky appearance will gradually disappear again and the voltage again drop, after which the charging should be continued until the cell becomes normal.

The loss of capacity due to the electrolyte falling below the top of the plates is not always realised. A drop of $\frac{1}{2}$ in. in the case of a plate measuring $7'' \times 7''$ means a reduction of area (and of capacity) by 7 per cent. Low level of the electrolyte also gives rise to corrosion of the positive plates at surface of the liquid, which is assisted by the fact that the specific gravity is lowest at the top, and corrosion proceeds most rapidly in weak electrolyte. "Topping up" water (which should be pure distilled water) should therefore always be added through a funnel and tube so that it reaches the bottom of the cell.

A BOARD OF INDUSTRY : TECHNICAL EDUCATION

Chairman's Address to Yorkshire Local Section

THE inaugural address to the Yorkshire Local Section of the Institution of Electrical Engineers by Mr. H. Hodgson Wright on November 11th was concerned solely with the war and its effect upon the nation from the engineering point of view. After mentioning the extent to which electrical engineering has entered into the present military and naval operations, he anticipates that once hostilities are ended the ability and organisation of Germany will be directed to underselling us in every market of the world. Prohibitive tariffs will, he thinks, to a large extent prevent Germany trading with Belgium, France, Italy, and Russia for many years, but whether we shall allow her to compete freely with us and our allies within the Empire was, he hoped, at least doubtful. To meet the new conditions after the war we must cheapen production by better organisation, improved machinery, designs, and co-operative sales methods. We require a higher and more general standard of specialised technical education for our engineers, in which matter Germany had gone ahead since 1870, and there must be a complete change of the old-fashioned sales methods, which many British manufacturers still continued, of waiting for customers instead of waiting on them. If financial reasons prevent the employment of a staff of highly salaried experts abroad, then co-operative sale methods must be resorted to. At the same time, however perfect we may be individually as salesmen, and however closely we might study foreign markets, there would still be wanting for complete success that organised State assistance which Germany has so lavishly expended upon her foreign industry. Our foreign trade will, said Mr. Wright, never be developed without diplomatic, legislative, and financial assistance. For this purpose a permanent and non-party board of industry was required, presided over by one of our most experienced business men, and advised by a permanent staff of experts.

The address concluded with some detailed references to the education and training both of workmen and young electrical engineers, capable of taking higher commands. So far as the

former are concerned, Mr. Wright advocates the leaving age for primary schools being raised, and finishing schools made compulsory, the last period at the primary school being devoted to apprenticeship training, during which a youth's aptitude or otherwise for engineering would be proved. In 1905 the Leeds Education Authority started as an experiment a day preparatory trades school for boys between 12 and 15 years of age, which has proved a decided success.

As to higher technical education for engineers, this should be sub-divided into "Design," "Works Management," and "Commercial Engineering," and in order to bring out the best that is in those being trained, there must be a closer association between the universities, technical high schools, and the engineering industry. At present much work was done of a purely academic character, which had little practical application. Great advantages would result to the electrical and engineering trades if they submitted to the universities for solution those problems which they have neither the staff nor the time to solve. This in turn could not fail to be of practical value in technical education, and would result in the teaching staff being kept in closer touch with industrial problems.

MICHAEL FARADAY PAPERS

AT the Institution of Electrical Engineers last Thursday, Mr. D. J. Blaizeley, whose wife is Michael Faraday's niece, presented to the Institution some papers of great historical value which had been left at his disposal by his sister-in-law, Miss Jane Barnard, who died in 1911. Miss Barnard lived at her Uncle Faraday's house until his death in 1867. The papers include:—

(1) Letters written to Faraday between 1845 and 1860, from Lord Kelvin, Clark Maxwell, and S. J. B. Morse. (2) Miscellaneous papers. (3) English letters to Faraday from Sir J. Clark, Sir Humphrey and Lady Davy, Charles Dickens, Sir C. Eastlake, J. D. Forbes, Sir W. Henschel, J. Nasmyth, R. Murchison, Lord Roscoe, and many others. (4) Foreign correspondence, including letters from Ampere, De La Rive, Bunsen, Dumas, Gay Lussac, and other well-known men of the period. (5) Three books of lecture notes written by Faraday himself. (6) Miscellaneous autograph letters of Faraday. (7) A book of chemical notes. (8) A book on "Nitrous Oxide," bound by Faraday himself. (9) Pamphlets on Spiritualism, Dry Rot in Timber, and other miscellaneous subjects.

A vote of thanks for this exquisite gift to the Institution was proposed by Dr. S. P. Thompson, who briefly referred to some of the events which were leading influences in the great man's career, particularly his Continental tour at the age of twenty-two as assistant to Sir Humphrey Davy. This journey, said Dr. Thompson, was to Faraday what a university education is to many young men; it changed him from a mere bookbinder's apprentice into an educated man able to think and reason in a scientific manner.

The vote was seconded by Mr. Mordey, who also presented the Institution with a copy of Faraday's "Philosophical Miscellany," which had been given to him earlier by Miss Barnard.

NEW PUBLICATIONS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

"Continuous and Alternating Current Machinery Problems." By W. T. Ryan. 37 pp. $7\frac{1}{2}$ in. by $5\frac{1}{4}$ in. 7 figures. (New York: John Wiley & Sons; London: Chapman & Hall, Ltd.) 2s. 6d. net; by post, 2s. 8d.

"The Testing of Machine Tools." By G. W. Burley. 231 pp. $7\frac{1}{2}$ in. by $4\frac{3}{4}$ in. 110 figures. (London: Scott, Greenwood & Son.) 4s. net; abroad, 4s. 4d.

"Mechanical Technology." By G. F. Charnock. 635 pp. $8\frac{1}{2}$ in. by $5\frac{1}{2}$ in. 503 figures. (London: Constable & Co., Ltd.) 7s. 6d. net; abroad, 8s. 5d.

"Overhead Transmission Lines and Distributing Circuits: Their Design and Construction." By F. Kapper. Translated by P. R. Friedlaender. 300 pp. $10\frac{1}{2}$ in. by $7\frac{1}{2}$ in. 297 figures. (London: Constable & Co., Ltd.) 16s. net; abroad, 17s. 1d.

"Handbook of Technical Instruction for Wireless Telegraphists." By J. C. Hawkhead. Second edition. Revised by H. M. Dowsett. 310 pp. $8\frac{1}{2}$ in. by $5\frac{1}{2}$ in. 242 figures. (London: Wireless Press, Ltd.) 3s. 6d. net; abroad, 4s. 1d.

"Electric Arc Phenomena." By E. Rasch. Translated from the German by K. Tornberg. 194 pp. $8\frac{1}{2}$ in. by $5\frac{1}{2}$ in. 52 figures. (London: Constable and Co., Ltd.) 8s. 6d. net; abroad 9s. 1d.

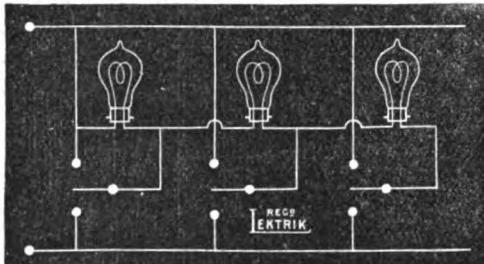

CORRESPONDENCE

ADJUSTABLE RESISTANCES..

To the Editor of ELECTRICAL ENGINEERING.

SIR.—Referring to "J. G. M.'s" reply to Question No. 1,468 in your issue of 11th instant, the variable lamp-resistance illustrated in the adjoining figure may be of interest. The arrangement was devised by Prof. J. D. Cormack, M.I.E.E.

The switches are of our two-way-off ("Duplex") type, and the combinations possible with three lamps and switches are as

follows: 3 series, 2 series, 1, 1 in parallel with 2 series, 2 par, 3 par. Assuming the resistance of each lamp to be 100 ohms, the resistances given by the above-mentioned groupings will be 300, 200, 100, 66·6, 50, and 33·3 ohms respectively.

With four switches and lamps, one can get 4 series, 3 series, 2 series, 1, 2 rows of 2 ser, 1 par with 3 ser, 1 par with 2 ser, 2 par, 2 par with 2 ser, 3 par, 4 par. At 100 ohms per lamp the resistances vary from 400 to 25 ohms.

Trusting this information may be of interest,

Yours faithfully,

A. P. LUNDBERG & SONS.
477, Liverpool Rd., Islington, London, N. Nov. 17th, 1915.

ELECTRIC TRACTION NOTES

Trial trips have been made on the Kingston loop of the newly electrified portions of the London & South-Western Railway Co. The service on this line is to commence on the 28th inst. We published a description of the general equipment of the line and the power-house in our issue for Sept. 23rd, p. 387, and Sept. 30th, p. 395. The first portion between Wimbledon and Waterloo is already working.

In his report upon the trade of Australia for 1914, H.M. Trade Commissioner states that contracts for machinery and plant for the electrification of the suburban railways of Melbourne, amounting to over £2,250,000, had been placed up to June 30th, 1914, and that work was in progress at the power-house at Newport, the car repair shops at Jolimont, and at the various sub-stations. The construction of new cars and alteration of existing cars is being carried out at the Newport workshops. It is proposed to instal the latest system of power and automatic signalling based on the best features of the system now in use on the Metropolitan and District Railways in London. An engineer of the Pennsylvania Railroad Co. has been engaged to superintend the installation of this signalling system. It was anticipated that the first section of the suburban line to be electrified would be completed about the end of this year, but delays have occurred due to the war, and it is uncertain when it will be completed.

The Stirling and Bridge of Allan Tramways Co., which at present runs a horse-car system, propose to convert to petrol-driven cars after the war. The Stirling Council is not convinced that this would be a satisfactory solution, and has intimated to the Company that further consideration of the matter should be postponed until after the war, when the Stirling Council itself will give a decision as to whether it will itself proceed with a scheme of electric traction.

CATALOGUES, PAMPHLETS, &c., RECEIVED

DOMESTIC ELECTRICAL APPARATUS.—A folder from Messrs. Haylock & Haslett (63 Queen Victoria Street, London, E.C.) deals with a series of "hot point" domestic electrical apparatus.

THE MAGNET OF COMMERCE.—With this heading the Great Central Railway Co. has issued a second edition of their booklet dealing with the various coalfields in reach of their railway system. At the same time a good deal of information is given with regard to the Company's new dock at Immingham.

HALF-WATT AND INCANDESCENT LAMP FITTINGS.—Engineering & Arc Lamps, Ltd (Sphere Works, St. Albans, Herts), has prepared a list covering a very complete range of requirements in the matter of half-watt and metal filament lamp fittings, both indoors and out. These fittings are all made at the St. Albans Works, but it is frankly admitted that some of them have been copied from German designs. This does not, however, apply to the details or the mechanical construction, which are claimed to be far more robust. For several types of fittings lanterns are supplied as an alternative to globes, which, owing to their excellent distribution and low cost of replacement, are becoming more and more popular.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Australia.—The Board of Trade Journal, quoting from the Melbourne Argus, states that the Queensland Minister for Works proposes to engage an electrical engineering expert to report as to erecting electric power and lighting stations at Brisbane and Ipswich.

Bo'ness.—The Secretary for Scotland proposes to instal new plant at an estimated cost of between £6,000 and £7,000 provided that it is urgently required to enable the undertaking to meet the demands of firms engaged on Government contracts.

Coventry.—A further expenditure of £30,278 upon new plant has been sanctioned by the Minister of Munitions.

London: Islington.—A loan of £5,455 for mains is recommended by the Finance Committee of the L.C.C., repayable in 25 years.

St. Pancras.—After a controversy lasting over a considerable period arrangements have at last been made between the Borough Council and the L.C.C. for a loan for the purchase of a new 5,000 kw. turbo-alternator, one of the terms being an acceleration of the repayment of certain outstanding loans on old plant.

Woolwich.—The Finance Committee of the L.C.C. recommends sanction to a loan of £4,700 in connection with the linking-up of the Borough Council's electricity undertaking with that of the South Metropolitan Electric Light & Power Co.

Uruguay.—The Canadian Department of Trade and Commerce at Ottawa, says the Board of Trade Journal, reports a demand for electrical machinery here.

Wiring

Cardiff.—Completion of electrical installation at technical college.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Cardiff.—New fire station.

Chesterfield.—Sanction has been given to a loan of £6,000 for extensions at Penmore Hospital.

Eastbourne.—New building for Prudential Assurance Co.

Miscellaneous

Australia.—The Deputy Postmaster-General, Melbourne, requires electric motors, polarised relays, Morse sounders, telephones, and voltmeters. Dec. 7th. He also requires common-battery, wall-pattern telephones. Dec. 14th. Further particulars at 73 Basinghall Street, E.C. These announcements are, of course, only of use to firms who can cable agents.

Japan.—Extensions to the Nagasaki tramways are contemplated. Further particulars at 73 Basinghall Street, E.C.

South Africa.—The South African Railways Administration requires a twelve-months' supply of rubber-insulated cable. Further particulars at 73 Basinghall Street, E.C.

APPOINTMENTS AND PERSONAL NOTES

At the Institution of Electrical Engineers last Thursday the retiring President, Sir John Snell, announced that M. Maurice Leblanc had been elected an honorary member of the Institution. M. Leblanc, in addition to his other scientific work, was one of the pioneers in the development of the modern alternator, and the invention of the Amortisseur or

damping coil was due to him in conjunction with his colleague Hutin.

In consequence of the absence of Capt. Wallis-Jones on active service, Mr. H. W. Couzens, of the firm of Couzens & Brown, has kindly undertaken to execute on behalf of Messrs. Wallis-Jones & Dent, all work now in hand and any future work that may be entrusted to the firm. The postal and telegraphic addresses will remain the same, but the telephone number will now be Victoria 5029.

Mr. B. Sleath, who travels for Messrs. Chamberlain & Hookham and Messrs. Venner & Co. in the west of England and South Wales, and Mr. J. S. Carter, who has recently been travelling in many parts of the world for Messrs. Chamberlain & Hookham, have both joined the Motor Transport Section of the A.S.C.

The whole of the male staff of the Hull Corporation Telephone Exchange marched to the Town Hall on Tuesday, headed by the Manager, Mr. T. Holme, and enlisted under Lord Derby's scheme.

The numerous friends of Mr. A. V. Gifkins, who was so seriously injured a short time ago in the recent Zeppelin raid, will be pleased to hear that he is making excellent progress, and hopes to leave hospital within a fortnight.

The Birmingham Electricity Department require a Telephone Inspector for private telephone system. (See an advertisement on another page.)

An Electrical Engineer is required by the Mexborough Council. (See an advertisement on another page.)

Mr. A. C. Bott, of Anglesea, has been appointed Resident Electrical Engineer by the Holmfirth District Council.

the rateable value of their premises by £1,000. It was pointed out that the Assessment Committee had made the increase in view of certain structural alterations at the works, and also by reason of an increase in the net profits of the undertaking during 1912-13 compared with the profits taken into account at the time of the last quinquennial valuation. Eventually the Court decided to reduce the proposed increase by £400, and held that an increase of £600 was justifiable.

Manchester: *The Barton Electricity Works.*—The Manchester Ratepayers' Association should by now have realised that its opposition to the new power scheme at Barton is futile, and it will be well advised to leave the Electricity Committee and the Corporation to develop the scheme upon the most natural lines. The President of the L.G.B. has replied to a further communication from the Association to the effect that in the opinion of the Board the Corporation has proper grounds for proceeding with the full scheme at the present time, and that the Board is not prepared to intervene in the matter. We gave a description of the station on page 379 of our September 16th issue, and Mr. S. L. Pearce, the Chief Engineer, gave similar information in a lecture to the Manchester Association of Engineers on Saturday last. As showing more than ever the absurdity of the arguments of the Ratepayers' Association, the Minister of Munitions has recently pointed out to the Corporation the enormous importance of adding to the quantity of electric power available in Manchester. The consumption during the past six months has been some 30 per cent. higher than in the corresponding half-year, and the Electricity Committee is doing everything possible to meet the increasing demands.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £97 10s. to £98 10s. (last week, £91 10s. to £92 10s.).

Liquidations.—A meeting of the creditors of Kyl-Fyre, Ltd., will be held at 72 Borough High Street, London, S.E., on December 2nd, at 2.30 p.m. Creditors are requested to send statements of claims to the liquidator, Mr. W. H. Cork, 19 Eastcheap, London, E.C.

LOCAL NOTES

Darlington: Electric Power Output.—As has been the case in all other manufacturing centres, the demands upon the electricity undertaking have been making rapid strides, and the Electricity Committee has been left with no alternative but to instal new plant. At the present moment a 3,000 kw. turbo-alternator is on order, and by the aid of this it is hoped to deal with the position for a short time ahead.

Dublin: Position of Electricity Undertaking.—In connection with a proposal to accept a tender for an underfeed stoker for the Pigeon House Fort power station, Mr. John Ryan, a member of the Corporation, said that as an expert would report upon the present position of the electrical undertaking and the means for remedying any defects that might be found, it would be better to postpone this matter. Eventually the report was sent back to the Committee.

Holmfirth: Progress of Electricity Scheme.—The buildings for the electricity works have now been erected, and most of the foundation work for the engines and plant completed. The laying of the cable in the central portion of the district is well in hand, and the contractors will shortly commence erecting the generating plant.

London: Kensington: Electric Supply Co.'s Assessment.—The Brompton & Kensington Electric Supply Co. appealed at the London Quarter Sessions last week against an increase in

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Edison & Swan United Electric Light Co.—At the meeting on Thursday the report and accounts given in our last issue were adopted. Mr. C. J. Ford, the chairman, who presided, said that the net profit for the year was £14,147, against £4,695 in the previous twelve months, but for the reasons pointed out in the report it was not proposed to declare a dividend. The directors thought it the wisest policy to keep the profits in the business rather than to divide them. With regard to lamps, there had been no difficulty whatever in disposing of the whole output, and, indeed, more could have been sold if the manufacturing capacity could have been greater.

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDING.

Drills, 6.25 to 7.25; 7.25 to 8.25 p.m.

(To-day) Thurs., Nov. 25th: Sections I. and II. and Signalling Section, shooting.

Fri., Nov. 26th: Sections III. and IV., technical. Sections I. and II., squad, signalling section, and recruits.

Mon., Nov. 29th: Sections I. and II., technical. Sections III. and IV., squad signalling section and recruits.

Tues., Nov. 30th: School of Arms with Architects Corps, 6.00 to 8.00 p.m.

Wed., Dec. 1: Opening of New Headquarters (See Below). 6.25 p.m.

Thurs., Dec. 2nd: Sections III. and IV., shooting.

Fri., Dec. 3rd: Sections III. and IV., technical. Sections I. and II., squad signalling section and recruits.

Technical drill at Headquarters, London Electrical Engineers.

Unless otherwise ordered, all parades at Chester House, Eccleston Place, S.W.

The opening of the new Headquarters takes place on Wed., Dec. 1st, at 6.25 p.m. All members are requested to attend in uniform if possible.

Members are requested to bring as many recruits as possible on this occasion.

Members desirous of applying for commission in the technical branches of the Army should apply immediately to the Commandant or Adjutant, who will give them all the information they require.

Arrangements for the Week.—(To-day) Thursday, Nov. 25th. Institution of Electrical Engineers. "Some Difficulties of Design of High-speed Generators," by Prof. A. B. Field. 8 p.m.

Tuesday, Nov. 30th. Manchester Section, I.E.E. Engineers' Club, Albert Square. "Some Difficulties of Design of High-speed Generators," by Prof. A. B. Field. 7.30 p.m.

Friday, Dec. 3rd. "The Generators." Dinner at Trocadero. 6.15 p.m.

SUMMARY

MR. G. SCOTT RAM'S annual report upon electrical accidents in generating stations and factories contains, as usual, a mass of interesting matter (p. 478).

SOME new American rules for flame-proof motors are discussed (p. 480).

A NUMBER of practical points in connection with the use of electricity in mines are discussed in a paper recently read before the National Association of Colliery Managers (p. 480).

THE importance of care in dealing with the bearings of electrical machinery is pointed out (p. 481).

AN electrical method of thawing frozen ground for mining operations has been patented (p. 481).

AMERICAN specifications for miners' electric lamps are reviewed (p. 482).

WE point out the classes of electrical workmen to whom, under Lord Derby's recruiting scheme, total exemption from military service, or some measure of exemption, is to be given (p. 482).

PROF. FIELD'S Paper on turbo-generator design was discussed at the Institution of Electrical Engineers in London on Thursday (p. 482).

AMONG the subjects of specifications published at the Patent Office on Thursday last are thermal meters,

duplex telephony, contactor switches, and single-phase motors. An application has been made for the suspension of an electrochemical patent. The B.T.-H. "dead man's handle" controller patent and a wireless telegraph patent expire this week after a full life of fourteen years (p. 483).

OUR "Questions and Answers" page this week deals with methods of dimming the lights of a small hall (p. 483).

A NUMBER of books are reviewed (p. 484).

THE Illuminating Engineering Society last week discussed the first report of the Home Office Committee on Factories and Workshop Lighting. A further report based on work already done will shortly be published, but the work of the Committee at the moment is at a standstill (p. 485).

AN important correspondence has passed between the Institution of Electrical Engineers and the Local Government Board on the question of the loan periods for electrical machinery (p. 486).

PARTICULARS are given of a number of contracts for telephone apparatus, tramways, and generating plant (p. 486).

DUBLIN wiremen have been granted an increase in wages of $\frac{1}{2}$ d. per hour.—Some interesting figures are given of the output of the Manchester electricity undertaking.—High-tension A.C. supply has been inaugurated at Gravesend (p. 487).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDING.

Drills, 6.25 to 7.25; 7.25 to 8.25 p.m.

(To-day) Thurs., Dec. 2nd: Sections III. and IV., shooting.
Fri., Dec. 3rd: Sections III. and IV., technical. Sections I. and II., squad signalling section and recruits.

Sat., Dec. 4th: Parade in uniform at East Putney Station at 2.45 p.m. Train Mansion Ho. Station, 2.22 p.m.

Mon., Dec. 6th: Sections I. and II., technical. Sections III. and IV., squad. Signalling sections and recruits.

Tues., Dec. 7th: School of Arms with Architects Corps, 6.00 to 8.0 p.m.

Thurs., Dec. 9th: Sections I. and II., shooting.

Fri., Dec. 10th: Sections III. and IV., technical. Sections I. and II., squad. Signalling section and recruits.

Sat., Dec. 11th: Instruction class at 2.30 p.m.

Sections for technical parade at Headquarters, London Electrical Engineers, 46 Regency Street, S.W.

Sections for shooting parade at miniature ranges.

Unless otherwise ordered, all parades at Chester House.

(For "Arrangements for the Week" see p. 487.)

ELECTRICAL ACCIDENTS IN POWER STATIONS AND FACTORIES

THE annual report of H.M. Electrical Inspector of Factories, Mr. G. Scott Ram, is, as usual, a thoroughly practical and interesting document. In his introductory remarks he calls attention to the evidence obtained by certain of the divisional inspectors who have assisted him that many contractors put in inferior apparatus and material, on account of cheapness, well knowing that it does not comply with the regulations, but afraid that other contractors are following the same course, and that in competition with them on the basis of plant complying with the regulations the order might be lost. The factory-owner eventually has to suffer, being put to greater expense in putting things in order than if he had paid for the proper material in the first instance. The obvious course for consulting engineers and owners is to specify that the installation shall comply with the Home Office regulations, and if it does not, then the contractor can be compelled to put it right. Having regard to the large amount of standard apparatus which is now made to comply with the regulations, the question of price is not so important as it was some time ago. Local contractors are beginning to realise that bad work is liable to be found out and condemned, and for this reason are improving their standard accordingly. The district inspectors' reports also call attention, among other details, to the inefficiency of earth connections, and high-tension switchboards having passage-ways only 18 inches wide with unprotected conductors along one side. Generally, the inspectors refer to the increased use of electrical energy for power purposes, but the usual estimate of the increase cannot be made, as the necessary returns from sources outside the Department are not available. Four prosecutions for breach of regulations were taken during the year, penalties of £5, £10, and £50 being imposed. The other case failed on legal technical grounds.

The mechanical accidents in electrical generating stations and sub-stations are fewer by 58 than in the previous year, a reduction of 13 per cent. The number of electrical accidents is slightly larger—99 as against 94 in the previous year, with four fatalities as against three. Under the first heading of the table some of the accidents were due to mistakes on the part of the switchman; others were due to matters beyond his control, either to faulty switchgear or to faults on the circuit at some distant point. In all cases the injuries were burns. In one the tank of an oil switch burst, and the attendant was injured by the burning oil. Six of the accidents occurred in the renewing of fuses.

TABLE I.—ACCIDENTS AT ELECTRICAL GENERATING STATIONS AND SUB-STATIONS IN 1914.

(The small figures relate to fatal accidents and are included in the principal figures.)

| Description. | | Stations for Public Supply and Electric Railways and Stat- Traways. | Tons. |
|---------------------------------------|----------------------------|---|-------|
| Non-Electrical :— | | | |
| At engines, pumps, and generators ... | ... 36 | 11 ^a | |
| At boilers and steam plant ... | ... 76 | 1 | |
| At coal-handling plant ... | ... 18 ¹ | 1 | |
| Falls ... | ... 97 ² | 5 | |
| Struck by falling bodies ... | ... 35 ² | 1 | |
| Miscellaneous ... | ... 88 ¹ | 12 | |
| Total ... | ... 350² | 31^a | |

Electrical :—

| | | |
|--|---------------------------|-----------------------|
| At switchboards when engaged in ordinary routine work ... | 19 | 7 |
| Cleaning, repairing, &c., at "live" switchboards or other "live" conductors ... | 29 ¹ | 20 ¹ |
| Cleaning, repairing, or other handling of switchboards supposed to have been made "dead" ... | 2 ¹ | — |
| Adjusting brushes and cleaning commutators and flashing at commutators ... | 2 | 4 |
| Miscellaneous ... | 13 ¹ | 3 |
| Total ... | ... 64² | 34¹ |

One half of the total accidents in electrical stations occurred to men when working on live conductors—mostly on switchboards. Eight occurred on extra high tension systems, and three on high tension systems. Two cases were fatal. One of these occurred in a consumer's sub-station to a man dusting a switch (5,000 volts) in a compartment with a door normally kept locked, but which he had himself opened. He was probably under the impression that the switch was dead, but the controlling switch in another compartment had been left "on." The other case occurred to a man working in an underground sub-station making contact with an inadequately protected tem-

porary cable (2,400 volts). In most of the high tension accidents the injured persons were doing work which was unauthorised and were themselves to blame. In one case an engineer attempted to do some work in a switch cubicle (10,000 volts). The switch was not in use, although live on one side, and it could have been made dead by means of the isolating switches provided for the purpose. This, however, involved the taking down of a heavy iron screen, and rather than take the trouble to do this he took the risk. This accident emphasises the desirability that such doors should be hinged or made to slide on runners so that they may be readily opened. One accident was caused through a short circuit to the framework of the switchboard by the metal end of the insulating pole provided for operating the isolating switches. One accident was due to the misunderstanding of a telephone message. Of the accidents on medium pressure and low pressure systems, 16 were caused by making short circuits with ordinary spanners, screwdrivers, or pliers. One accident was due to short circuit in attempting to remove the tank on a live oil switch. Two other fatal accidents under this heading were reported, but they are not included in the table as they did not occur on premises under the Act. One was in a switch-house on a 10,000-volt system, and the other at a transformer box in the street at 2,400 volts.

The remaining fatality occurred owing to an engineer-in-charge taking hold of live conductors of a high-tension arc lighting switchboard presumably thinking they were dead. A switch controlling the switchboard had apparently, contrary to the usual custom, been left on inadvertently from a previous shift. The victim was no doubt to some extent blameworthy in not ascertaining for himself whether the board was dead.

Under the miscellaneous accidents the fatal case occurred to a man who touched with his head a neutral conductor of a high-tension alternator. Several alternators were running in parallel, the neutral point of one being definitely connected to earth. It had previously been assumed that the neutral points of the other machines would have been very nearly at earth potential. In this case it proved that there was 500 volts pressure to earth. The machines were of different types, and the one in question was of lower voltage than the others and connected through a step-up auto-transformer.

TABLE II.—ELECTRICAL ACCIDENTS IN FACTORIES OTHER THAN ELECTRICAL STATIONS IN 1914.

(The small figures relate to fatal accidents and are included in the principal figures.)

| | |
|---|-----------------------------|
| Arcing of { switches | ... 38 |
| fuses | ... 9 |
| Shock or burns when replacing fuse wires | ... 22 |
| Portable apparatus, connectors, and flexible wires | ... 65 ^a |
| Unprotected conductors, switches, terminals, fuses, &c. | ... 36 ^a |
| Working on live electrical apparatus or conductors: | |
| Skilled persons | ... 42 ¹ |
| Unskilled persons | ... 46 ² |
| Miscellaneous accidents in electrical manufacturing and repair works—mostly in testing operations | ... 55 ¹ |
| Adjusting brushes and cleaning commutators and flashing at commutators | ... 6 |
| Miscellaneous | ... 31 ^{2*} |
| Total ... | ... 350¹⁴ |

The electrical accidents in factories are fewer by 68, or 16 per cent., than in the previous year, the number of fatalities (16) being one less. The accidents in renewing fuses afford examples of the dangers of different types of fuses to which attention has been drawn in former reports. Most of the injuries are burns from short circuit, but some from shock. In some cases short circuits were made by getting the fuse wire or pliers or other tool across the terminals of both poles or between one pole and the metal case. In some instances the fuses had been protected by a switch, but this being at a distance was not used. In other cases, where there was a switch at the fuses it was connected on the wrong side so that the fuse terminals were live whether the switch was "on" or "off." Several occurred with fuses in porcelain carriers having the fuse wire in a groove in the front of the porcelain. In these cases the fuse having blown, the attendant replaced it without having investigated and rectified the fault which caused it to blow in the first instance, with the result that immediately the fuse holder with the new fuse wire was put into contact, the fuse blew again, burning his hand. Others, causing shock, occurred with the "bobbin" or "grip" type carrier having live metal at each end of the porcelain. None of the above arrangements of fuses complies with the Regulations. Fuses not protected on the live side by switches should be of the switch-fuse type so constructed that the hand when grasping the handle cannot touch live metal and is shielded from the arc should a fuse blow when being plugged in.

Of the accidents in the use of portable apparatus, 26 occurred in handling the flexible conductors. One case, having fatal

* One fatality, fall following shock.

results, occurred to a man when working on the wet floor of a dry dock. He was engaged in scraping a ship's bottom and is supposed to have trodden on the flexible cable of a portable lamp cluster, a nail in his boot piercing the insulation of the cable. In many works there is no proper examination of the flexible conductors which remain in use after being badly damaged and worn out. In some cases the metallic armouring of the flexible wires had broken and pierced the insulation. Metallic armouring, especially in the form of a wire helix, is not a desirable form of protection. The earth connection is liable to become disconnected, and through rough usage and constant bending the wire is apt to break and pierce the insulation, and becoming live is very dangerous. Other forms of protection, such as rubber or hard-core braiding, are generally preferable. Twenty of the accidents occurred in connecting the flexible wires to the circuit. In six cases "adapters" were being put into lamp-holders and short circuits occurred. In other cases pin plugs of the old type were used, the wires short-circuiting at the point where they enter the plug. In most of these cases the use of safety-type hand shield plugs would have prevented the accidents. The short circuits which occur in this way are often very heavy, leading to very severe burns, by reason of the circuit being too heavily fused. In one case it was found that the circuit for a hand lamp was fused for 60 amperes. Three cases of shock occurred from unearthing portable drills. Some cases of shock from hand lamps also occurred. One fatal case—also in a dry dock—occurred in the use of a portable "cargo lamp," a cluster of several lamps being mounted in a metal reflector. The whole fitting became live by reason of a terminal screw in one of the lamp-holders being in contact with the barrel of the holder. The man took hold of the reflector of the fitting and was killed. The fitting was not earthed and was not in accordance with the requirements of the Regulations. It is noteworthy that safety-type cargo fittings have been devised and are now on the market.

Under the next heading, "Unprotected Conductors," there were seven fatalities, of which six were due to contact with overhead wires. The wires, although out of reach from the ground, were so placed that workmen in the course of their duties might have at some time to get into close proximity to them. In one case wires covered only with braiding were run out of doors close to a steam valve. A man had to get to the valve and came into contact with the wires (440 volt 3-phase) and was killed. The braiding of wires without any insulating covering is quite useless, and may lead persons erroneously to suppose that they are insulated and safe to touch. The next case was similar, the bare wires although out of reach from the ground were within reach from a pipe bridge on which the man got in the course of his duties. He made contact with the wires and fell to the ground, a distance of 11 ft., and although he died from the results of the fall, he was able to state that he received a shock. The next case occurred at a wharf where pit props were unloaded and stacked. The wires were 22 ft. from the ground, but the props were stacked in some places to within 3 ft. of the wires. The supply was 440 volts, 3-phase. A man on one of the stacks touched the wires and was killed. The next case was also on a 440 volt, 3-phase system. Bare wires were run under the roof of a large engineering shop. Men were at work painting the roof and one of them took hold of the wires and was killed. His mate managed to hold him until assistance came and he was lowered to the ground. Another case was similar in all respects except that the system was 400 volts, 3-phase. Two men tried to get the victim off the wires, but themselves received shocks and he fell to the ground. In the other similar fatality a man was sent to clean out a gutter close to which were live wires at 500 volts, 3-phase. The seventh fatal case occurred in an engineering works to a man touching the live parts of a 240-volt, 3-phase switch which had no cover and which he had to use. It was a throw-over type of switch having double blades at right angles on each pole so arranged that in grasping the handle the hand would be liable to touch the projecting blades of the outgoing side. Of the non-fatal accidents nine were in connection with electric cranes. Five were by men touching the bare trolley wires when getting in or out of the cage. Four were due to unprotected conductors in the cage.

Under the next heading, "Skilled persons working on live conductors," the fatality occurred on a 440-volt, 3-phase system. Alterations had to be made to a motor circuit, and the electrician cut into a live wire with a pair of pliers. It was found that the fuses protecting the circuit had been removed from two of the wires, but not from the third. The accidents under this heading might for the most part have been avoided if the work had been done at night when the works were shut down. Several occurred at switchboards when tightening nuts with ordinary uninsulated spanners.

The corresponding accidents to unskilled persons are less excusable, as the men should not have been allowed to attempt the work. In many works, sometimes even in large works using a very considerable amount of electric power, no technically qualified person is employed, and unskilled workmen are consequently permitted to attempt repairs or alterations at great risk to themselves. The two fatalities occurred on travelling cranes. In one case the driver was oiling the gear on the crab crane. In the other a fitter was repairing the crane and came into contact with the

live trolley wires. In both cases the system was 440 volts, 3-phase. Of the non-fatal accidents the victims were described as labourers (13), fitters (9), bricksetters, oilers, &c. They were mostly attempting to do some work on the electrical apparatus for which they were quite incompetent.

That the testing of electrical apparatus in electrical manufacturing works is largely carried on by apprentices and pupils is again indicated by the ages of the persons meeting with accidents. The fatal accident occurred, however, to an experienced electrician, who touched wires at 2,000 volts apparently under the impression that they were dead. Artificial respiration was carried on for two hours without success. In another case a man touched some testing leads at 12,000 volts pressure. He was rendered unconscious, but was brought round by artificial respiration. In the other cases the injuries were mostly burns from short circuits. The testing departments of electrical manufacturing works are often carried on in a very unsatisfactory manner. There is unnecessary exposure of live conductors where they are liable to be accidentally touched. Any old connecting cables with damaged insulation are considered good enough. Even in high pressure testing unnecessary risks are run. In one large armature winding shop it was customary to test the armatures by applying 2,000 volts between the commutator and the spindle. A twin flexible cable was connected to a transformer in a cabin, the other end being moved about to whatever part of the shop a test was required, perhaps twenty or thirty yards from the cabin. The cable terminated in bare ends projecting from short vulcanite sleeves. There was only one tester, who could, of course, not be at both ends of the cable at the same time. An accident occurred at an armature under test, the armature winder, who was applying the ends of the test leads, getting a shock. The tester was walking back to the test cabin where at the moment there was no one to switch off the current. In this shop also there was no one qualified or instructed in first aid methods, someone having to be fetched from another department of the works.

Amongst the miscellaneous accidents there were three fatalities. One occurred to an electrician in a large iron works in switching on a lighting circuit transformer, arranged across one phase of a 460 volt 3-phase system, at a totally enclosed ironclad switch, the case of which was not earthed. The switch was of a well-known type, having fuses in the same box so arranged that when the switch is in the "off" position the fuses are withdrawn from the contacts, and by opening the cover they can be renewed in safety. The apparatus was intended by the makers for use with cartridge type fuses. As so often happens, however, the cartridge fuses had been replaced by wires. The electrician in question had the duty of switching on the lights at dusk, and in order to prevent other employees switching on before the proper time, it appears that he had disconnected one end of one of the fuse wires and had closed the cover of the switch. Later on, when he went to turn on the lights, he had evidently forgotten that the fuse was disconnected, and the effect of putting the switch to the "on" position was to make the fuse wire live and bring it into contact with the metal case, giving him at the same time a shock which proved fatal. The accident would, no doubt, have occurred to any other employee attempting to turn on the lights. At the inquest it was urged that the apparatus was advertised as being "fool-proof." It is evident that this description requires some qualification. In the second fatal case the man received a shock from a 200 volt 2-phase motor, the frame of which was live and not earthed. He was about to start up the motor and had turned on the main switch, but not the starting switch. He was engaged in shifting the belt on to a loose pulley and his hand was trapped between the pulley and the belt. A man who went to his rescue also received a shock. The third fatality occurred to a boy, who climbed up on to a roof where he had no business, and took hold of two wires of a 440 volt 3-phase system. Amongst the non-fatal accidents two were due to stay wires of poles becoming live. In one case an electrical engineer took hold of a stay wire and was unable to let go. His two assistants, who were fortunately at hand, succeeded in pulling him off by his clothes. The system was 440 volts 3-phase, and the leakage was due to the failure of an insulator.

(To be concluded.)

Institution of Electrical Engineers.—The following is the result of the ballot for the election of new members, and transfers from one class to another, at the meeting on Thursday.
Members: H. E. Brockwell, F. A. Nield. *Associate Members:* E. Graves, C. E. Wright. *Graduates:* J. M. Bhattacharjee, A. M. Bower, J. W. Collett, J. S. Jenkins, A. Lauder, C. H. Sparks, G. M. Templer. *Students:* T. B. Berry, J. E. Brigg, W. B. Coulthard, E. E. de Boissière, A. C. Ferreira, E. Forster, H. J. Hindom, R. M. Holland-Pryor, A. Howard, I. Levy, R. E. M. Linay, W. Moore, B. M. Murray, J. E. Price, A. Raistrick, J. W. Ryde, D. H. Simmonds, F. Smith, E. Walker, H. B. Warden.

Candidates transferred:—*Associate Member to Member:* L. G. Caunter. *Graduate to Associate Member:* S. Burns. *Student to Associate Member:* D. B. Da Cunha, H. J. Eley, W. A. Hatch, A. F. Sykes. *Student to Graduate:* A. L. Bedford, L. M. Jockel.

ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Published on the First Thursday of each month

AMERICAN RULES FOR FLAME-PROOF MOTORS AND ACCESSORIES

AN excellent set of rules has been drawn up by the American Bureau of Mines, specifying the precautions to be taken in the manufacture of explosion-proof motors and accessories.

The design and construction must be especially durable, and the protective devices used must not only be capable of preventing the passage of flames from the interior to the exterior of the motor casing, but must also possess sufficient mechanical strength to insure against the accidental destruction of their protective qualities.

Starting rheostats and other necessary equipment that may cause an ignition of gas must be protected as adequately as the motor itself. The casings of starting rheostats must be explosion-proof. The resistances and contacts of the starting rheostats used with portable motors of not more than 50-h.p. capacity should be enclosed in the same box, unless enclosed in separate boxes connected by approved piping through which all leads are carried. All leads entering the explosion-proof casing of a starting rheostat should pass through the casing in the form of properly-protected insulated studs of approved design. The use of rubber bushings will not be approved, because the bushing may become displaced and thus destroy the explosion-proof quality of the casing. The casing of the starting rheostat should be mounted on the motor casing, if possible, and the intercommunicating openings for the passage of leads should be made large in order to prevent the rise of pressure that always attends the propagation of an explosion through a small hole from one compartment to another. If it is not possible to mount the starting rheostat on the motor frame, all leads connecting the starter with the motor should be carried in rigid metallic conduit.

Unless means for opening the circuit both automatically and by hand are provided in a separate explosion-proof casing, they should be incorporated in the design of the starting rheostat. If the starting rheostat is mounted on the frame of the motor, provision should be made for entirely disconnecting the electric circuit from the starting rheostat.

All joints in the casing of a motor or of any of its accessories must be metal-to-metal joints with faces not less than 1-in. wide, and if the pressure developed in the motor casing by explosions can exceed 50 lb. per sq. in., the faces must be not less than 1½ in. wide. All bolt-holes must be bottomed or so arranged that the accidental omission of a bolt will not give an opening through the casing. All openings in the motor casing other than those provided with protective devices by the manufacturers must be tightly closed. It is desirable that such openings be as few as possible. There should be no exposed terminals or contacts outside the motor casing. If there are glass-covered openings in the casing of a motor, the glass should be of ample thickness and should be protected by strong metal covers that close automatically unless held open by hand. Armature bearings must be so designed that under no circumstances can an explosion be propagated from the interior of the motor casing around the armature shaft or through the oil wells.

If there are any sliding or rubbing contacts in connection with the cable reel, such contacts should be provided with explosion-proof protection, and any plug connections should be constructed so that they will be explosion-proof. At the point where trailing cables enter the frames of portable motors, the cable should be protected with suitable armour or flexible metallic conduit, securely fastened to the frame of the motor, and of a sufficient flexibility to prevent short bends from occurring in the cable. The cable should not be fastened to this armour, but there should be provided inside the frame of the motor an insulated clamp of approved design for securely fastening the cable and taking all mechanical strains that may be put upon it.

In testing a motor to establish its permissibility, the motor casing will be filled and surrounded with the most explosive mixture of Pittsburgh natural gas and air. The motor will then be operated at its rated speed and the mixture within the casing ignited by a spark plug, by a spark from the motor

brushes, or by any other means that simulates the conditions of actual practice. Similar tests will also be made with greater and with less amounts of gas in the explosive mixture and with coal-dust sifted into the motor casing or into the protective devices.

Tests will also be made to determine the point of ignition that gives the greatest pressure, and tests will be made by igniting from such a point. In order for a motor to pass these tests, it shall in none of them cause an ignition of the gas surrounding the motor or discharge flames from any part of the motor casing. Neither shall the motor develop dangerous after-burning or excessive pressure in the case of the motor or its starting rheostat.

PRACTICAL POINTS FOR COLLIERY MANAGERS

AT a recent meeting of the Lancashire Branch of the National Association of Colliery Managers a Paper was read by Mr. Ralph R. Smith on "Practical Points in Connection with the Use of Electricity in Mines."

The subject of switchgear was first treated. It was stated that preference should be given to switches of the oil-immersed type, and, in general, selection of switchgear should not be governed by price, but requirements should be stated to manufacturers of repute, when satisfaction would be assured. The chief points to be considered are strength, simplicity, liberality in design of copper parts and of insulation, and absence of all possibility of open sparking or risk of shock. Switchgear should be of the floor-mounting type in preference to wall-mounting, as in the latter case the walls are apt to "squeeze," and break the switch-frames.

Turning to a consideration of motors, the author said these should be chosen with an ample margin for overload, and with due regard to the class of work to be done. For instance, a squirrel-cage motor, although the hardest and least susceptible to sparking, will not start up under a heavy load, such as a haulage gear. Slip-ring and continuous-current motors, however, will start up under very heavy loads. It is a good plan where motors up to, say, 80 or 40 h.p. are working in a damp or dusty atmosphere to have them totally enclosed, as that preserves the insulation of the windings. With larger motors than this, special arrangements have to be made, because a totally-enclosed motor will only develop about half its horse-power, the output being limited by the temperature rise.

Attention was called to the importance of the size of the air-gap. Alternating-current induction motors have a very small clearance between the rotor and stator, and the danger, of course, is that the bearings will wear and allow the rotor to foul the stator, thereby causing a burn-out of the windings. For mining work, it is advisable to choose a rotor with a large air-gap, and sacrifice to some extent the efficiency. Some makers have adopted an adjustable bearing which adds to the reliability of the motor and the life of the bearings.

With regard to cables, the most suitable type for mining work was the bitumen-insulated, as water has little or no effect on it.

The author next turned attention to the subject of power distribution. Three-phase current, he said, has advantages over direct current owing to its ease of transformation to different voltages, its consequent suitability for long-distance transmission at high voltage with a minimum of loss due to resistance, and the saving of copper that can be effected. A.C. motors are less liable to breakdown or sparking, and commutator troubles are eliminated. He recommended the use of high voltage for motors of 50 h.p. and upwards, in order to do away with transformer losses.

On the subject of earthing, the best way to accomplish this, said Mr. Smith, is to secure a suitable place on the surface to bury a main earth-plate. The ground should be of a damp, clayey nature. Two earth-plates, about 4 ft. square, connected together at about 20 to 30 yards apart, are much more effective than a single plate twice the size. All electrical apparatus working with a voltage exceeding that of low pressure should be earthed. A very important point is not to rely upon the cast iron of the switch cases and joint-boxes to

form part of the circuit, as cast iron has a very high resistance. In all such cases the switches, &c., should be bonded. In addition to this, it is advisable to have two distinct earth connections to all apparatus, so that if one works loose there is always a safeguard. A good way to ensure against loose connections is to use lockwashers on all joints; this also applies to the live conductors.

The best way to test an earth circuit was stated to be as follows:—Disconnect both plates from each other, and with a low-reading ammeter and voltmeter, and about three or four dry cells, see how much current can be sent from one plate to the other through the earth, with a certain voltage. The Board of Trade standard for this is that a pressure of four volts shall suffice to pass a current of 2 amperes from one plate to another, through the earth. In this case the resistance works out to 2 ohms. Under these conditions one can feel quite content about the main earth-plates.

The author then read, in a form suitable for issuing with instructions to electricians and others, a list of faults likely to cause shocks or breakdowns. The more important of these are as follows:—

Cables: Slinging unarmoured cables without regulation slings, insufficient number of slings, passing between roof and beams, or between wall and props, abrasion of covering, damp situation, inefficient bonding of armouring, joints without boxes.

Motors: Excessive heating, excessive vibration, oil leaking from bearings, faulty connections, sparking, wearing of bearings, accumulation of oil and dirt on the windings, oil rings not rotating.

Transformers: Excessive heating, insufficient oil.

Switches & Starters: Dirty or insufficient oil, loose nuts, bad contacts, defective springs, water on or near switches, oil creeping along cables.

Earth Wires: Broken or damaged, hanging loose, connections badly made, loose or dirty, signs of corrosion, twisted joints.

Lighting: Wires too tightly stretched or too slack, joints not insulated, lamps and wires likely to catch persons passing, &c., wet places, defective fittings.

Accessories: Defective rubber gloves (rubber gloves much safer when faced with leather), wet or dirty sand.

Mr. Smith concluded his Paper with an explanation of his arrangement of signalling underground to prevent open sparking by putting the wires together. One wire is run on one side of the road and one on the other, insulated or bare as desired, and in one of the lines, usually the manhole side, about every 75 yards a small pull switch is inserted which is flame- and explosion-proof. It then requires only a slight pull at any portion of the wire to make contact from inside the switch to the wire on the other side of the road. The wire with the switches inserted is supported on the props by being passed through porcelain tablin insulators. The system is very simple and cheap, and has so far given remarkably good results.

BEARINGS OF ELECTRICAL MACHINERY

THE electrical engineer has not only to keep bearings in good running order, but on occasions has to decide which type of bearing is most suitable for certain conditions of load. In a recent paper before the West of Scotland Branch of the Association of Mining Electrical Engineers, Mr. Andrew Gibson dealt with the whole subject of bearings of electrical machinery in a comprehensive manner. At first sight it would appear, he said, that problems regarding bearings are easy of solution, but that this is not so had been proved by mysterious cases of heating and seizing of a perfectly sound bearing which, perhaps, was one of three identically the same on the same shaft. The remarkable effect of a thin film of oil in an ordinary bearing had been well shown in Beauchamp Tower's famous experiments, which showed that a steel shaft in a gunmetal bearing lubricated with sperm oil seized at a pressure of about 600 lbs. per square inch under steady running, whereas when dry the same materials seized at about 10 lbs. per sq. in.

The oily or greasy film between the shaft and the bearing seems to act in the same way that a great number of metallic balls would, by supporting the load and keeping the surfaces apart. The breakdown of this film allows the surfaces to come together, and the consequent metallic friction, producing heat, to all intents and purposes welds the two surfaces together. The load at which this occurs depends chiefly upon the viscosity of the oil, in which temperature plays an important part. The thicker and less free-flowing an oil is the greater unit pressure it will stand in a bearing without squeezing out. A very light spindle oil, for instance, will stand, say, a pressure of about 50 lbs. per sq. in., whereas a cylinder oil of good body will stand a pressure of over 2,000 lbs. per sq. in. on the same bearing. Therefore, the unit pressure which any bearing will stand depends chiefly upon the lubricating film, which in turn is influenced by the arrangement of the bearing surfaces.

The allowance commonly made for the running fit of the

bearing and shaft is about $0.0005 (D+1)$, where D is the nominal diameter of the shaft in inches. Some manufacturers of fast-running machinery make the diameter of the bearing exceed that of the shaft by nearly twice that amount. This clearance allows the shaft to take up an eccentric position in the bearing, leaving a space on the side from which the load is applied. It is at this point that the lubricant should be introduced, so as to spread itself upon the shaft, adhere to it, and travel round upon the surface, being forced between the bearing surfaces at the pressure necessary to support the load.

The cutting of oil grooves in bearings is a matter requiring extreme care and attention, as a groove placed where the oil is under pressure would act merely as a collector for the oil, and provide it with a path of escape before it had accomplished its purpose. As much thought and care should be given to the grooves as to the rest of the bearing, and it should be kept in mind that their function is to distribute the oil between the bearing and shaft where the load is not supported.

With regard to ball bearings, the author pointed out that these fulfil the condition of reducing friction to the lowest possible amount, and better, perhaps, than any other type, but there are certain disadvantages with them. The principal one seems to be delay in the working of the machine if repairs have to be made to the ball bearing. Nevertheless, there is a growing demand for them for all classes of machinery because of their free-running properties and the small amount of attention required to maintain them. An important point is to have self-aligning ball bearings, because a bearing which cannot adjust itself to suit the shaft requires extreme accuracy in fitting up, and the least inaccuracy in alignment and housings results in wedged and broken balls and abnormal wear.

ELECTRICAL MINING PATENTS FOR NOVEMBER

THE only electrical patent of mining interest published during last month is for an electrical method of thawing frozen ground for mining operations in cold climates, which is described by J. R. Quain in Specification No. 20,721 of 1914. A spiked tool containing a heating element, which is resiliently mounted to be unaffected by shocks, is driven into the ground.

ELECTRIC MINING LAMPS IN AMERICA

A N interesting Paper was read before the West Virginia Coal Mining Institute by Mr. H. H. Clark, of the United States Bureau of Mines, and we give the following information from an abstract recently published in the *Colliery Guardian*. It appears that the Bureau of Mines has been encouraging the development and adoption of portable electric mining lamps for some years as a measure of safety. They have issued a set of specifications, which include a fair amount of detail. The lamps are to contain a device which will extinguish the lamp as soon as the bulb is broken. The minimum amount of light recommended is the amount given by a good safety lamp, but almost every electric lamp submitted to the Bureau gave more light than this. The time of burning was set at 12 hours, in order to leave a margin over usual hours of use.

Considerable emphasis is placed upon the distribution of light. A narrow ray of light giving contrasting areas of light and shade is not approved of, and the Bureau asks that the angle of the ray should be so large that the light is thrown practically everywhere that a man's eye could turn. To secure a longer life and more uniform performance than hitherto in the actual lamps, the Bureau has prepared a specification to which some lamp manufacturers already adhere. Great stress is placed upon the importance of mechanical details in the construction of the complete lamp. One of the parts that has given considerable trouble is the flexible wire connecting the headpiece and lamp on the miner's cap to the battery. It is this part which has given out most frequently in the cases investigated by the Bureau. In conclusion, emphasis is laid upon the necessity of selecting a capable man to take charge of the lamp-house, and mention is made of the fact that electric lamps require less lamp-house space per lamp than oil lamps, and this should be borne in mind when adopting them.

THE ELECTRICAL INDUSTRY AND RECRUITING

A LTHOUGH the list of trades which are vitally important at the present time for war work or for other essential requirements, and the list of reserved trades essential for the maintenance of some other branches of trade and industry, are not yet complete, it is possible from the lists which have already been published to gather some idea of the extent to which the electrical industry will be exempt from recruiting under Lord Derby's scheme. To begin with, the whole of the employees in public utility services, which include electric supply and tramways, are indicated as reserved occupations, but this list is subject to reconsideration according to circumstances. This action on the part of the Reserved Occupations Committee, which, it is said, is sitting daily, will, at any rate, remove to some extent the anxiety which many central station engineers have been put to in order to keep their staffs either from enlisting or going elsewhere by the attraction of higher wages. It has been urged for a long time that an official pronouncement of this character would imbue the men with a full sense of their responsibility, and cause them to remain in their positions. Incidentally, it may be here pointed out that the Local Government Board is understood to be considering the whole position of placing employees at electricity works on the same footing as employees working in Government factories, thus giving an electricity committee the right to object before a Munitions Tribunal to men leaving their service for enlistment or other purposes. In the same reserved class are included electricians engaged upon the maintenance and repair of tools and machinery of any sort. Among the trades in the list of those vitally important at the present time for war or other essential requirements are included wiremen and electricians engaged in shipbuilding or upon ships, as well as armature-winders and electrical instrument makers. Similarly, all classes of workers below ground in mines come within the same category, and among the workers above ground are included electricians.

Fire Damp Detector.—A pamphlet has been issued by The General Electric Co., Ltd. (67 Queen Victoria Street, London, E.C.), describing the "Migas" detector. This is an instrument for determining rapidly and accurately the percentage of fire damp (marsh gas) in the air at any point. It is stated that a reading can be taken in about 15 secs., and its accuracy depended upon to within 0·03 per cent. The detector is made in two forms, the "standard," which indicates from 0 to 3 per cent. of inflammable gas, and the "naked light" form, which is specially designed for high accuracy between 0 and 1 per cent. The latter is intended for use in collieries in which naked lights are permitted. The instrument is strong and portable, weighing about 13 lb.

TURBO-GENERATOR DESIGN

T HE Paper on the design of high-speed turbo-generators, summarised in our last issue, was read by Prof. A. B. Field at the Institution of Electrical Engineers in London last Thursday. The meeting was held in the library of the Institution, and Mr. C. H. Wordingham, who presided, said they were gathered in the library as "in the case of certain events it might be safer" than the lecture hall.

The discussion on the Paper was opened by Professor S. P. Thompson, who referred to the core discs $2\frac{1}{2}$ in. thick without any central core, and asked what was the basis for the statement that the plate construction gave a rotor as rigid as a solid one. He also regretted the American frequency of 60 cycles per sec., as against the standard frequency of 50, which was now being almost universally adopted. Dr. Thompson also made use of the opportunity to call members' attention to the interesting old Holmes machine in the basement of the Institution (see ELECTRICAL ENGINEERING of August 19th, p. 347).

Mr. F. H. Clough (B.T.-H. Co.) approved of the method of rating the machine given in the Paper, and said that under the old rating standards, with their overload allowances, and making provision for the power factor, he assumed this machine would be about 14,000 kw. With regard to the rotor construction, he considered the use of through shafts quite feasible on machines of this size, and their use would permit of ventilation holes through the rotor and hence a smaller diameter of machine. Then he thought the machine would have been cheaper had it been designed with less flux and higher current density. He did not agree with the making of rotors without fans in order to shorten them and run them below critical speed. It was quite feasible to run above critical speed. With regard to the rotor winding, pressure on the slot portion of the winding was not essential, as this pressure could not be placed on the end bends. The elaborate rotor coil bracing he thought unnecessary, as, owing to the large angular momentum of the coils when in motion, there was little risk of their being moved by the retarding forces on short circuit.

Mr. H. Burge (Crompton & Co.), referring to the plate construction of the rotor, questioned whether the plates would not be liable to rotate with respect to one another on short circuit. He approved of the magnetic wedge described, and said that even on small machines the use of an iron wedge might reduce the iron losses by 50 per cent. He advocated the use of stranded conductors for avoiding eddy losses.

Dr. S. P. Smith asked why it was considered advantageous to run rotors below their first critical speed; if the running speeds of these machines were to be thus limited, we should very soon come to the limits of output of turbo-generators. With regard to the built-up rotor, he thought a solid rotor with bolts through, as described, might be as strong or better in some ways.

Mr. W. M. Mordey said the feature of ability to stand short circuits on test should be insisted upon in specifications for turbo-generators. Short circuits should be required on full load (with full steam pressure behind), as well as on no load.

Mr. R. Livingstone (Dick, Kerr & Co.) did not think that the time had yet come in this country for the use of such large machines as the one described, and attention might usefully be devoted to smaller units. With regard to the use of magnetic material for end bells, he thought the difficulties caused by leakage were generally over-estimated. He thought that in power stations of the future more elaborate provision would be made for the provision of special ventilating plant, including the necessary apparatus for washing the air.

A communication was read from Professor Miles Walker, in which he said that he considered solid forged rotors would be suitable for machines up to a size of 50 inches and 1,500 r.p.m. He thought forgings of sufficient strength and reliability could be obtained. With reference to the edge-wound rotor coils described in the Paper, he considered they were suitable for machines up to this size, but for larger machines better construction would have to be adopted, and lantern slides were exhibited showing a type of construction having concentric space end connections for the rotor winding.

Professor Field, in replying to the discussion, said that it had been his experience in the United States that solid forgings of suitable strength could not be obtained for rotors. In replying to Dr. Thompson, he said that stiffness of the rotor was proved by its high critical speed. With regard to the rating of machines, he considered the new standard ratings very much better, as machines are more likely in the future to be run continuously at or near full load. Regarding the feasibility of using through shafts instead of rotors, he did not deny this at all, but did not consider there was any advantage in doing so. He considered that the bracing of rotor windings, as he had described, was most essential, as the retarding forces on the coils were enormously large. He had seen large square shafts twisted by these forces, and inspection of some old machines whose windings had not been braced led him to believe that these would cause trouble in the future.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 25th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

21,792/14. **Thermal Meters.** P. M. LINCOLN. A wattmeter comprising two derived circuits traversed by two superposed currents, one of which is proportional to the voltage and the other to the amperage of the circuit in which the energy is to be measured. These currents are additive in one of the circuits and opposed in the other. Means are associated with each circuit for receiving and temporarily storing during a definite time the energy effect therein, and means are provided for indicating the difference between the average stored during the period in question. (One figure.)

22,554/14. **Duplex Telephony.** BRITISH INSULATED & HELSBY CABLES, LTD., W. P. FULLER, and H. H. HARRISON. A system of duplex telephony over long lines, in which the physical and phantom circuits are simultaneously loaded by a single inductance coil of special construction, without the production of a stray field. (Eight figures.)

23,544/14. **Contactors.** B.T.-H. Co. (G.E. Co., U.S.A.). An electromagnetic lock-out switch having an armature acted upon by two opposing magnetic forces, and an auxiliary armature adapted when the switch is excited to place a spring under stress, the force of which causes the switch to close when the exciting current falls to a value at which the spring force exceeds the difference between the opposing main forces. (Eleven figures.)

4,079/15. **Single-phase Motors.** J. L. ROUTIN. The combination of several single-phase motors with slip-rings connected to suitable points on their armature windings, arranged in parallel. The stator of each has two coils, one to neutralise the self-induction of the armature and the other, not in series with the rotor winding, fed at constant pressure with a suitable phase difference from the supply voltage. (One figure.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Arc Lamps: STEVENSON and WILLIAMS [Span wire arc lamp suspension] 21,706/14; UCAR [Establishing an arc between electrodes not in contact] 2,349/15.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: W. T. HENLEY'S TELEGRAPH WORKS CO. and SAVAGE [Gripping cables] 2,289/15.

Dynamos, Motors and Transformers: B.T.-H. Co. (G.E. Co., U.S.A.) [D.C. dynamos] 22,131/14; KUYSER [Dynamo] 22,383/14; COLLET [Generating set] 6,098/15.

Electrometallurgy and Electrochemistry: NELSON [Electrolytic cells] 9,411/15.

Heating and Cooking: HOLDSWORTH [Electrically heated boilers] 1,892/15.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no

Incandescent Lamps: GROTE and REYNOLDS [Tungsten filaments] 22,057/14; KUYSER [Dynamos] 22,383/14.

Storage Batteries: NAYLOR [Accumulators] 3,326/15.

Switchgear, Fuses and Fittings: IGRANIC ELECTRIC CO., LTD. (Cutler Hammer Mnf. Co., U.S.A.) [Electromagnetic switches] 3,837/15, [Pressure actuated switches] 4,561/15, and [Controllers] 5,001/15.

Telephony and Telegraphy: MUIRHEAD & CO. and SQUIER [Telegraphy] 22,265/14; KERSTING [Intercommunication telephones] 22,549/14.

Miscellaneous: MAITRE and MARTIN [Contact breaker for electromagnetic vibrating members] 3,583/14; BEIN [Watertight bells] 21,536/14; GOLDSTONE [Dry battery torches] 2,036/15; KILNER [Bells] 9,441/15.

The following Amended Specification is now available:—
Telegraphy: V. BOUCHARDIN [Polyphase wireless sender] 18,009/14.

Amendment made

19,484/14. **Radiators.** P. GOOD and A. E. WOODHOUSE. This specification for a former for heating elements for electric fires has been amended by references to Patents Nos. 21,557/10 and 17,945/14.

Application for Suspension

605/09. **Electrochemistry.** SIEMENS BROS. & CO., LTD. (Siemens & Halske.) An application for the suspension of this patent of enemy origin has been made by the Refractory Zinc Ore Treatment Co., and will be heard on December 10th. The specification describes the electrolysis of aqueous saline solutions by means of manganese dioxide electrodes.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

24,807/01. **Traction Controllers.** B.T.-H. CO. (F. Case, U.S.A.). Controllers with a form of the "dead man's handle" feature, which breaks the circuit when the driver relaxes his grip of the handle.

24,825/01. **Wireless Telegraphy.** J. A. FLEMING and MARCONI'S WIRELESS TELEGRAPH CO., LTD. A wireless sending system, in which two or more subsidiary condensers are placed in the secondary circuit of the transformer, besides the active condenser in circuit with the primary of the oscillation transformer.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: F. M. LEWIS [Arc lamp carbons] 18,469/09.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: A. M. BOURKE [Insulators] 18,690/09.

Electrochemistry and Electrometallurgy: H. SCHMIDT [Electroplating] 18,043/07.

Ignition: C. A. VANDERVELL [Magneto switches] 534/09.

Storage Batteries: A. M. TAYLOR [Battery boosters] 18,636/09.

Switchgear, Fuses and Fittings: G. WILKINSON [Automatic transformer switches] 17,786/06; F. SCHOFIELD, E. EDWARDS, and C. TICKELL [Tramway signals] 4,600/09.

Traction: E. G. PINK [Overhead conductors] 18,499/09.

award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,471.

I have about twelve motors, varying in size from 30 to 200 h.p., running on a 25-cycle, 3,000-volt system, all driving haulage gears. I propose to double this number of motors, at least, and to add motors up to about 500 h.p. for driving heavy haulages, air compressors, &c. Would it be efficient and worth the extra capital outlay for more flexible running and standardisation, &c., to change my system, to, say, 40 or 50 frequency? In order to do this I have to add considerably to my power-

station units. In this case I should have to scrap the above 25-cycle system or instal some method for running 25-cycle motors from a new system of 40 or 60 cycles, assuming that my existing 25-cycle generators require absolutely renewing. What is the best arrangement for running 25-cycle motors from a 40-cycle system? And what are the principal factors to take into consideration for embarking upon such a scheme.

"REPRESENTATIVE."

(Replies must be received not later than first post, Thursday, Dec. 8th.)

ANSWERS TO No. 1,469

The lighting of a small hall is effected by 54 metal-filament lamps connected to a 100-volt A.C. supply of 50 periods per second frequency. What is the best method of using choking coils for dimming purposes, on two groups of 26 100-watt lamps and 20 32-watt? The remaining eight lamps are 40-watt, and require no dimming. How does the candle-power of a lamp vary with the applied voltage?

The first award (10s.) has been made to "Arc" for the following reply:—

Since the lamps in any one of the two groups are to be dimmed simultaneously, the simplest arrangement is to connect two choking coils, one in series with each group, the chokers being each fitted with tappings and a switch, so that the number of turns in circuit can be varied. Such an arrangement is described and illustrated in Maycock's "Alternating-Current Work," pages 220-1.

As regards the variation of the candle-power of metal-filament lamps with the voltage, this is given approximately by the expression $C.P. = kE^2$, where k is a constant. From this expression the first two columns in the following table have been calculated, the first column being the percentage of the normal candle-power of the lamp, and the second being the corresponding voltage across the lamp.

| Percentage candle-power. | Volts across lamps. | 26 100-watt lamps. | | 20 32-watt lamps. | |
|-----------------------------|------------------------|--------------------|-------------|-------------------|-------------|
| | | Current. | Inductance. | Current. | Inductance. |
| 100 | 100 | 26 | 0 | 6.4 | 0 |
| 90 | 97.5 | 25.5 | .0027 | 6.27 | .011 |
| 80 | 94.6 | 24.9 | .0040 | 6.12 | .017 |
| 70 | 91.4 | 24.2 | .0053 | 5.96 | .022 |
| 60 | 87.9 | 23.5 | .0064 | 5.78 | .026 |
| 50 | 84.1 | 22.6 | .0076 | 5.57 | .031 |
| 40 | 79.4 | 21.6 | .0089 | 5.33 | .036 |
| 30 | 74.0 | 20.4 | .0105 | 5.03 | .042 |
| 20 | 66.8 | 18.8 | .0126 | 4.64 | .051 |
| 10 | 56.2 | 16.4 | .016 | 4.04 | .065 |

If L be the inductance of the choking coil required to cause a certain reduction in the candle-power, and if R and I be respectively the corresponding resistance of the group of lamps, and the total current through them, then

$$100 = I \sqrt{R^2 + (2\pi \times 50L)^2}.$$

Now the resistance of the filaments does not remain constant, but decreases as the lamps are being dimmed. This can be taken into account thus:—The relationship between the current and the candle-power for metal-filament lamps is given roughly by $C.P. = k_1 I^2$, where k_1 is a constant. From this equation the third and fifth columns in the table have been calculated. The resistances of the lamps in both groups are then found from the ratio of the voltage to the corresponding current, and the inductances are afterwards determined from the expression given above.

The second award (5s.) is given to "L. R." for the following reply, which we have abridged:—

The best method of using choking coils for the purpose suggested depends to a large extent on the effect desired, and the existing switching arrangements. It may be required to have a continuously variable dimming scheme, or a form with two points only, such as lights full on, lights dim. Again, the groups may be controlled by a single switch or by a series of switches.

Assume for the moment that each group has a double-pole switch controlling it. Then probably the most convenient method would be to use an auto-transformer connected across the mains at this switch, and tap off whatever voltage be required to give the desired effect.

With an ordinary metal-filament lamp a reduction of about 5 per cent. in the voltage reduces the candle-power by approximately 15 per cent. A reduction of 10 per cent. lowers it by about 25 per cent., whereas with a reduction of 50 per cent. it only glows. From these figures the kind of voltage change can easily be determined, and one can make two or three tappings if desired.

If an auto-transformer cannot be employed, then a choking coil would be introduced to give a similar voltage drop, and it is quite likely that the standard transformers and chokers

used with alternating current arc lamps can be applied, but that depends on the particular case.

An ordinary 100- to 110-volt transformer of this kind gives 75 volts on the secondary, and the choker reduces this to 42 volts. Such a choker carries anything up to 15 amperes, which seems to be about the correct size in the present case.

Again, it may be possible to use one auto-transformer for supplying the two groups of lights. A standard choking coil with iron core and air-gap can be readily adapted, if not already suitable, by adjusting its air-gap.

REVIEWS OF BOOKS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

The Wireless Telegraphist's Pocket Book of Notes, Formulae, and Calculations. By J. A. Fleming, F.R.S. 347 pp. 7½ in. by 4½ in. 38 figures. (London : Wireless Press, Ltd.) 6s. net; abroad 6s. 3d.

ONE of the most remarkable features of this work is a compressed treatise on mathematics, embracing a vector analysis and many other refinements in tabloid form occupying no more than 54 pages—a task that few would dare attempt. The remainder forms an admirable bridge between mathematics and practice, and discusses the quantitative aspect of high frequency currents and their application in transmitting and receiving circuits, besides giving a host of useful practical information for operators as well as designers, and a selection of conveniently arranged tables.

Experimental Physics. A Text-book of Mechanics, Heat, Sound, and Light. By H. A. Wilson. 405 pp. 8½ in. by 5½ in., 235 figures. (Cambridge : The University Press.) 10s. net; abroad, 10s. 7d.

THE scope of this book is indicated in its sub-title—"A text-book of mechanics, heat, sound, and light." It is intended as a text-book for use in connection with a course of experimental lectures. Although no previous knowledge of physics on the part of the reader is assumed, a thoroughly sound knowledge of elementary mathematics is essential in order to derive the greatest benefit from the book. The principles of the subject are treated accurately, and the experiments described are well chosen; but there is something in the author's style and method which makes the book unnecessarily "hard reading." This will, however, possibly be alleviated when the student can actually see experimental illustrations.

An Introduction to Applied Mechanics. By E. S. Andrews. 316 pp. 9 in. by 5½ in., 205 figures. (Cambridge : The University Press.) 4s. 6d., abroad, 5s 5d.

This differs from the old text-books in that it is much more practical and not merely a treatise of applied mathematics; at the same time, the author has avoided the danger of going to the opposite extreme, as some more recent writers have done, by giving too much engineering application without sufficient explanation of fundamental principles. Among the best features of the book are its excellent diagrams, the numerous worked examples and well-chosen numerical exercises, and concise summaries of the chapters. The whole subject, though copiously illustrated by experiment and example, is treated in a continuous manner, and in logical sequence throughout.

A First Course in Engineering Science. By P. J. Hales and A. H. Stuart. 191 pp., 7 in. by 5 in., 159 figures. (London : W. B. Clive.) 2s. 6d., by post 2s. 9d.

Although not going far enough for the serious student of engineering, this small volume forms a very good popular introduction to the subject. The first part deals with applied mechanics, and the second with heat and the steam engine. The authors have made themselves acquainted with the recent Board of Education Memorandum on engineering teaching in evening schools, and have made a praiseworthy attempt to cover the ground allotted to the first year of the major course of "engineering science," and at the same time to conform with the syllabus of the City and Guilds' examination in Mechanical Engineering, Division I., Grade I.

The Testing of Machine Tools. By G. W. Burley. 231 pp. 7½ ins. by 4½ ins. 110 figures. (London : Scott, Greenwood & Son.) 4s. net; abroad 4s. 4d.

THE treatment of the subject covers the three general sections : (1) shop tests, i.e., tests made to keep up the standard of the machines so far as accuracy is concerned; (2) commercial tests, having as their immediate object the improvement of the output and the general conditions of operation; and (3) scientific and laboratory tests, made for the information of the designer as well as the user. While the book discloses little that is novel to the competent engineer, it undoubtedly contains much useful information on the subject.

THE LIGHTING OF FACTORIES AND WORKSHOPS

A DISCUSSION took place at the meeting of the Illuminating Society on Tuesday, November 23rd, upon the first report of the Home Office Committee on the Lighting of Factories and Workshops. This report was summarised in our issue for September 16th, p. 378, and the discussion was opened by Mr. L. Gaster, who was a member of the Committee. The object of the discussion was to secure from those interested in the matter suggestions for the future guidance of the Committee, which has at present another report in preparation based upon the work already done. Further work, however, is, not unnaturally, for the moment held up.

Mr. Gaster summarised the report of the Committee and put forward a number of points which he considers worthy of further consideration. It is not without interest to point out, however, that although one of the reasons why Government action was secured in this country in this matter was the repeated statements that Governments in many other countries of the world had taken the problem in hand officially, yet the outstanding facts by which the Committee was faced was the absence anywhere in the world of any general provisions in respect of lighting of the kind in question. The report contains a summary of the legislation bearing upon industrial and school lighting in the chief European countries and the United States of America, but many of the regulations were introduced a number of years ago. The result is that the Committee's report can, without exaggeration, be said to be the most complete publication on industrial lighting in the world.

As we have already pointed out, the general recommendation of the Committee was that a minimum of 0·25 ft. candle should at some future date be specified by legislation as the minimum illumination for storage, passages, stairways, &c., leaving the actual working place to be dealt with as a separate problem. Emphasis is laid upon the point that this is the *minimum*, but in many cases the *desirable* illumination might be a good deal higher. From Mr. Gaster's remarks it is clear that there is considerable work still awaiting the Committee as regards the effect of glare, and the avoidance of excessive contrasts in illumination. There is room also for a detailed and systematic study of the requirements in regard to lighting in specific industries, whilst information gained during the past twelve months has shown a definite relationship between illumination and the physical condition of workers. A Department Committee under the auspices of the Home Office and the Minister of Munitions has recently been appointed to deal with the subject, and there is every prospect of co-operation between this Committee and the Factory Lighting Committee.

Several speakers took part in the discussion, and all with one exception were in complete accord with the suggestions and recommendations in the first report. Mr. G. Campbell, however, went so far as to stigmatise the report as a dismal failure from the point of view of its recommendations. He contended that an illumination of 0·25 ft. candle for factory lighting would be totally inadequate for 99 per cent. of cases, and suggested that a minimum of from 1 to 3 ft. candles would not be too much.

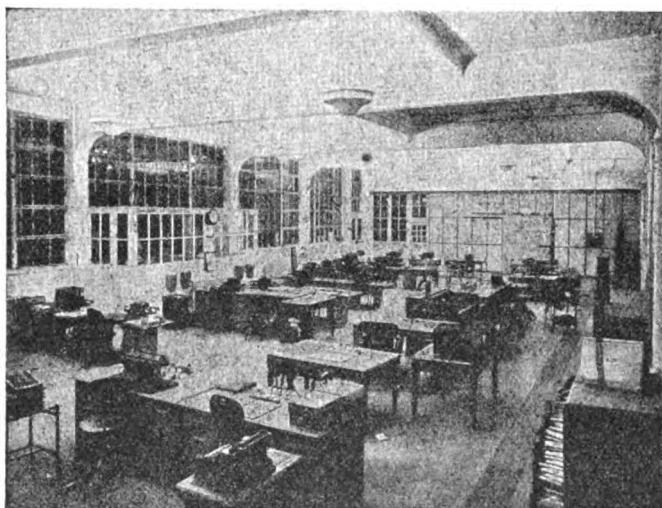

The relationship between fatigue and illumination was mentioned by one or two speakers, but the most interesting speech was that by Mr. A. Cunningham, of the London & South-Western Railway, who dealt with the question of lighting railway goods yards. He contended that 0·25 ft. candle would be an unreasonably high degree of illumination in many railway goods yards, and instanced a 14-acre yard belonging to his Company in which the present lighting is considerably less, although it is ample in his opinion. To increase this to a minimum of 0·25 ft. candle would be to increase the annual cost for current alone from £300 to £1,500. Incidentally, mention may be made of the fact that the Committee propose an exemption clause for special cases, and probably railway goods yards would come within this category.

Summing the discussion up, it may be said that a splendid start has been made by the Committee, and that there is practically no controversy as to the soundness of the views it has already expressed. At the same time, experience goes to show that even now there is room for a considerable amount of educational work amongst factory owners, the examples of badly lighted factories being all too frequent. The best line of argument with such owners, of course, is to impress upon them the intimate relationship between efficient lighting and both the quality and quantity of the output.

The B.E.A.M.A. Annual Dinner.—We are informed that the British Electrical & Allied Manufacturers' Association will not give an annual dinner for the session 1915-1916.

A MODERN LIGHTING INSTALLATION

YET another fine example of thorough efficiency in office lighting arrangements is shown in the accompanying illustration, which depicts the typist's room of the Chiswick Polish Company. The installation has been carried out with Mazda "eye-rest" fittings. In each of the handsome bowls shown

there are five Mazda lamps in separate X-ray reflectors, throwing light on to the white ceiling, whence it is reflected. The quality of this artificial illumination is seen by the fact that the photograph was taken by the artificial light alone, although even the reproduction of the photograph does scanty justice to the actual brilliancy of installation.

OSRAM LAMPS AND THE WAR

THE large response of the electrical industry to the call for recruits has resulted in difficulties for the lamp manufacturer as well as for other departments of electrical enterprise. At the same time, the war has created many special demands for lamps and so encouraged makers to maintain the standard of technical progress and productive efficiency. At the Osram-Robertson Lamp Works (Hammersmith, London, W.), for instance, the management has been able, since the war broke out, to effect a steady improvement all round. Reports of the National Physical Laboratory comment upon the fact that the wattage and candle-power of Osram drawn wire lamps correspond with exceptional accuracy to the standards in each case. This is all the more satisfactory inasmuch as every part of the Osram drawn-wire lamp is produced in this country. The bulbs are produced in Great Britain, and at Hammersmith every process of manufacture is carried out by British workpeople, from the treatment of the tungsten ore to the finished filament, including the making of the supports, hooks, caps, and other details.

"Industries of the Empire Fair."—A preliminary prospectus of the proposed Industries of the Empire Fair to be held at the Palace of Industry, Willesden Green, London, N.W., from March 6th to March 25th, 1917, has been sent to us. The organisers, whose offices are at Lincoln House, High Holborn, W.C., urge British manufacturers to prepare for the position after the war. The Industries of the Empire Fair is not a private enterprise, but is controlled by the principal trade associations of the Empire, which will refund to the exhibitors in the form of a bonus, in the same way as is done with the electrical exhibitions, any profit accruing from the Fair.

The Electric Vehicle Committee.—A note from the Honorary Secretary of the Electric Vehicle Committee comments upon the fact that the Manchester Corporation has recently served notices upon a large number of owners and tenants in that city to abate an alleged nuisance by discontinuing to keep horses on their premises. The obvious bearing of this upon the future of the electric vehicle industry is clear, and Sanitary Committees and other municipal departments are reminded that there is nothing experimental about the modern electric vehicle.

The L. & S.W. Railway Electrification and Telephones.—It is stated that the postponement of the date for the commencement of running the electric train service on the Kingston loop line of the L. & S.W. Railway, announced in our last issue, is due to an alleged interference with the telephone circuits at one portion of the line. Necessary adjustments, however, are being made, and it is hoped that the service will be brought into operation before the end of the year.

LOAN REPAYMENT PERIODS

AS was mentioned in the annual report of the Council of the Institution of Electrical Engineers, the question of obtaining an alteration in the periods at present allowed for the repayment of loans for electrical plant has been under consideration for some time, and the *Journal* of the Institution for December 1st reproduces correspondence which has passed between the Council and the President of the Local Government Board on the matter. The Institution asked for a period of 30 years for all classes of underground mains, instead of the present 25 years for the solid system, 15 years for armoured cables laid direct in the ground, and 20 years for armoured cables coated with jute and bitumen and covered with bricks. It was further suggested that in the case of cables drawn into substantially constructed conduits, the cost of the latter, and of laying them, should be spread over a period of sixty years. For storage batteries 15 years was suggested instead of the present 5 years, and for reinforced concrete work 30 years instead of the present 15. At the same time it was suggested that a deputation should wait upon the President of the Local Government Board.

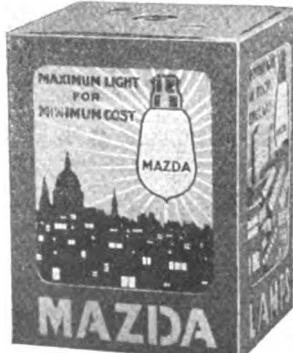

The reply from the Local Government Board, which was dated August 10th last, stated that it was not thought a deputation was necessary. With regard to underground cables it was pointed out that the period has been recently altered to 25 years for all types, and no longer period can be allowed. As to conduits, the Institution's proposal of 60 years was not assented to, but the Board will be prepared to grant 30 years in suitable cases when asked for. The present period of 5 years for storage batteries is to be increased to 7 years, but the Board will not make any alteration in the present period for reinforced concrete work.

LUNDBERG SWITCHES

WE have received from Messrs. A. P. Lundberg & Sons (477-489 Liverpool Road, London, N.) a copy of the handsome and well-printed 4to volume of some 90 pages, which constitutes their new List No. 1. Notwithstanding its size, the list deals only with four of the firm's many types of Tumbler and other small switches—namely, "Single Way," "Twinob," "Double Pole," and "Triple Pole," the prices of "Two-Way" switches being also given. The book contains over 200 illustrations, and a considerable portion of it deals with the thirty or so different kinds of single-way switch and modifications thereof. These thirty kinds are divided into five groups, viz., tumbler, turn, push and pull, pendant, and miscellaneous, and as regards modifications it may be mentioned that the "pivot" switch, for example, can be supplied with one or more of about ten different modifications in its standard construction. As usual with the Lundberg publications, extreme care has been taken in the arrangement, the diagrams of circuits which are given being exceedingly helpful. The dimensions also are given both in inches and millimetres, and the full range of catalogue numbers renders ordering from the list free from any possible misunderstanding.

A MAZDA LAMP SHADE

THE British Thomson-Houston Co. (Mazda House, 77 Upper Thames Street, London, E.C.) have designed the lamp shade shown in the accompanying illustration to assist in carrying out the existing lighting regulations. One of the main objects in view was to deal with railway carriages upon lines running underground for any considerable part of their journey. These Mazda shades are now to be seen, among

others, on the Great Western and Metropolitan Joint Railway, between Hammersmith and New Cross. They are of rectangular construction, one side being opaque and the other three framing transparencies of the very effective design reproduced. The new shade is also available for use in contractors' and dealers' windows, or in conjunction with the Mazda revolving shade, the new type forming a splendid advertisement, besides serving a utilitarian purpose under present conditions.

CATALOGUES, PAMPHLETS, &c., RECEIVED

FACTORY HEATING.—A combined steam heater and electric propeller fan system for factory heating is described in a folder from the Ventilating Engineering Dept., General Electric Co. (67 Queen Victoria Street, E.C.). The unit comprises a battery of cast-iron gilled radiators enclosed in a strong sheet-steel casing, at the top of which is mounted an electric propeller fan fitted to a continuous- or alternating-current motor, the current consumption being approximately 220 watts. The fan blows the air downwards through the heater and distributes it near the floor level.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

CARBON FILAMENT LAMPS.—A two-page pamphlet from Pope's Electric Lamp Co. (Hythe Road, Willesden, N.W.) deals with carbon filament lamps. The company will be pleased to supply to, and overprint for, trade customers in quantities.

TENDERS INVITED AND PROSPECTIVE BUSINESS

In consequence of certain restrictions placed upon technical papers by the Press Bureau, it is not possible, during the present war conditions, to give our readers as much information as hitherto in these columns.

Generating Stations, Sub-Stations, Mains, &c.

Australia.—The Deputy Postmaster-General, Sydney, requires 3,750 common battery, automatic wall pattern telephones; 300 common battery table pattern telephones; 150 wall sets, magneto telephones; and 50 portable telephones. Dec. 20th. Also a common battery multiple switchboard for six subscribers' sections. January 19th.—The Deputy Post-Master-General, Brisbane, requires telephone instruments, parts, and accessories. January 26th.

The Metropolitan Board of Water Supply and Sewerage, Sydney, requires electrically-driven centrifugal pumps. Dec. 20th.

This information is only useful to firms having agents who can be instructed by cable, but copies of specifications, &c., may be seen at 72 Basinghall Street, S.W.

The Berrigan (N.S.W.) Council proposes to instal an electric power station. The name and address of the consulting engineer is on file at 73 Basinghall Street, E.C.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

Brighouse.—New mill. Architect, E. C. Brooke, Central Chambers.

Hitchin.—New premises for Capital & Counties Bank, Ltd., corner of Brand Street.

Miscellaneous

Australia.—The Footscray (Victoria) Council contemplates the installation of electric trams. The name of the consulting engineer is on file at 73 Basinghall Street, E.C.

New Zealand.—The Public Service Stores Tender Board, Wellington, N.Z., requires 6,700 telephone cords and 120 miles of rubber-insulated twin twisted wire. Further particulars at 73 Basinghall Street, E.C.

Diesel Engine Association.—At the November meeting of this Association questions relating to income-tax assessment and allowance for depreciation of Diesel engine plant, price of fuel oil, and cracked and seized pistons were discussed. We will deal more fully with the meeting in our next issue. The next meeting of the Association will be held on the 20th inst.

LOCAL NOTES

Belfast: *Loans Refused.*—The Treasury has intimated to the Corporation its inability to sanction any further loans for mains and services. Consequently, the Electricity Committee will be unable to accept any new applications for supply.

Blackpool: *Threatened Strike of Employees.*—Practically the whole of the employees of the Corporation recently threatened to strike unless increases of wages were granted. After consideration of the position by the Sub-Committee, it has been decided by the men to accept a bonus of 2s. for those earning up to 30s. per week, and 1s. for all earning between 30s. and 35s. The men are also to have a bonus not paid since May owing to a misunderstanding.

Dublin: *The Wiremen's Dispute.*—Although a short time ago it was stated that the dispute between the wiring contractors of Dublin and their employees had, so to speak, come to an end automatically by reason of the fact that many of the men had obtained employment in munitions factories, there has nevertheless been an arbitration, over which the Recorder of Dublin has presided. The present rate is 9d. per hour, but the men demanded an increase of 1½d., as well as a war bonus. The arbitrator's decision is that the men should be granted an increase of 1d. per hour, making 9½d., but an addition of 6d. per day is to be paid to men engaged on War Office work.

Explosion in Sub-station.—There appears to have been a very serious explosion in a Corporation sub-station only a few hundred yards away from the Ringsend power station on Saturday. At the moment the cause of it has not been definitely ascertained. There seems no electrical theory to account for it.

Gravesend: *High-Tension Supply.*—The feature of the past year's working of the electricity undertaking has been the inauguration of high-tension A.C. supply. Hitherto, direct current only has been available. There was a net surplus of £827 for the year, notwithstanding £1,378 extra cost of coal, higher wages, and war allowances.

Liverpool: *Increased Charges.*—An increase of 12½ per cent. in the charges for electricity is recommended, to start in the new year.

London: Poplar: *The "Contract" System.*—The Electricity Committee states that it cannot recommend any reduction, notwithstanding the reduced lighting regulations, in the fixed charge per kilowatt to consumers who are upon the contract system, either for inside or outside lighting.

Manchester: *Output of Electricity.*—At the last meeting of the Electricity Committee it was stated that the output of the Department in the preceding week was the record of 720,000 units, whilst the maximum load on the undertaking during that period was 55,000 kw. It was further stated that difficulties are still being experienced in the matter of coal supplies, the amount received from the contractors being very much below that contracted for. The consequence is that there has had to be recourse to the reserve supplies.

Middlesbrough: *The Electric Transporter Bridge.*—An interesting point was mentioned at the last meeting of the Corporation in connection with the energy consumption of the electrically-driven transporter bridge across the Tees. It was stated that whereas during a given period on a calm day only 87 units were used, during a similar period on another day with a strong wind blowing this was increased to 184 units.

Wirral: *Electric Supply.*—An application by Messrs. Johnson & Phillips for the Council's permission to apply for an electric lighting Provisional Order has been adjourned for a month.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £98 10s. to £99 10s. (last week, 497 10s. to £98 10s.).

Competition.—The recent offer of two guineas for a suitable house name for the new premises of the Electrical Supplies Co. at 233 Tottenham Court Road, London, W.C., brought in nearly 200 names. The judges, after considerable discussion, eventually decided that "The Light House" was the most

suitable for the purpose, and as no fewer than six competitors submitted this same name it was decided, in consequence of this unexpected development, to increase the prize from two to three guineas to enable each successful competitor to receive the sum of half-a-guinea. The names and addresses of those who sent in "The Light House" will be sent to anyone interested.

Agencies.—The *Board of Trade Journal* points out that a British engineer in Moscow desires to represent United Kingdom manufacturers of dynamos, electric lifts, &c. Further particulars at 73 Basinghall Street, E.C.

A Johannesburg agent desires to represent United Kingdom manufacturers of electrical fittings, wires, &c. Further particulars at 73 Basinghall Street, E.C.

Brazil.—According to the *Board of Trade Journal* there is an urgent demand for electric lighting appliances among other goods in various States in Brazil. Further particulars are available at 73 Basinghall Street, but it is pointed out that the districts referred to are full of German settlers and traders.

Trade with New Zealand.—The Commercial Intelligence Branch of the Board of Trade is notified that the Wellington (N.Z.) Chamber of Commerce is organising an exhibition of goods of British manufacture to be held during one week in February next. It is suggested that British firms who are unable to supply the New Zealand market at the present time, either at all or on the same terms as previously, should endeavour to keep their names before the public, not only by participating in the exhibition, but also by carrying out a campaign in the local Press, pointing out exactly why their goods are not obtainable at the moment, or why they are perhaps higher in price.

Dissolution of Partnership.—The partnership between P. L. Dwyer and P. R. Winterson, trading as P. L. Dwyer & Co., electrical manufacturers and suppliers, 66 Victoria Street, London, S.W., has been dissolved. P. W. Dwyer continues.

APPOINTMENTS AND PERSONAL NOTES

The appointment of Mr. R. H. Scotson, Electrical Engineer to the Middlesbrough Corporation at a salary of £300 per annum is recommended. We reported a short time ago that Mr. H. M. Taylor, the Borough Electrical Engineer hitherto, had received a commission in H.M. Forces. It is stated, however, that the matter of this appointment is to be raised before the Council meeting.

Works Manager for motor and electrical engineering factory in the Midlands. (See advertisement on another page.)

The Bennett College require Tutor in electrical department. (See advertisement on another page.)

Oldham Electricity Department want a Shift Engineer. (See an advertisement on another page.)

Canterbury Electricity Works want a Switchboard Attendant. (See an advertisement on another page.)

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

"Z" Electric Lamp Mfg. Co.—Mr. Justice Astbury, in the Chancery Division on Wednesday last week, sanctioned a reduction in the capital of this Company from £150,000 to £15,000. During the course of the proceedings it was stated that the chief loss was in respect of the value of the Company's patents.

Durham Electrical Power Distribution Co.—The capital of this Company was reduced from £500,000 in £5 shares to £300,000 in £1 shares in the Chancery Division on Wednesday last week. It was stated that capital to the extent of at least £200,000 has been lost or is unrepresented by available assets, a position said to be due to the vast changes in the methods of electrical generation and distribution since the Company was incorporated in 1899.

Arrangements for the Week.—*Fri., Dec. 3rd.* "The Generators." Dinner at Trocadero. 6.15 p.m.

Wed., Dec. 8th. Institution of Electrical Engineers. Yorkshire Section. Philosophical Hall, Leeds. "Some Difficulties of Design of High-speed Generators," by Prof. A. B. Field. 7 p.m.

Association of Engineers-in-Charge. St. Bride's Institute, Bride Lane, E.C. "Ammunition Manufacture." By A. E. Perin. 8 p.m.

SUMMARY

FURTHER reference is made to the Annual Report of H.M. Electrical Inspector of Factories. A number of miscellaneous matters are also dealt with, including lead poisoning in accumulator factories, the lighting of factories, and the electrical disposal of dust and fumes (p. 490).

WE give the complete list, to Nov. 20th, of those members of the Institution who have lost their lives fighting (p. 491).

A NEW lamp has been developed in which an arc burns between tungsten electrodes in a bulb containing an inert gas. It has an efficiency of half a watt per candle, a life of several hundred hours, and the light is emitted from almost a point. The size of the bulb is smaller than that of a half-watt incandescent lamp. Lamps are about to be made from 200 to 2,000 c.p. (p. 492).

AMONG the subjects of specifications published by the Patent Office last Thursday are water-tight bells, metal filaments, telegraphy, cables, and electro-magnetic switches. Opposition has been entered to an engine starter patent and withdrawn from an indicating electric moving-target patent.—A patent for an A.C. automatic signalling system expires this week after a full life of 14 years (p. 493).

OUR Questions and Answers page this week deals with the welding of copper wires by the use of welding transformers (p. 493).

AN interesting discussion took place at the last meeting of the Diesel Engine Users' Association on the subject of cracked and seized pistons (p. 494).

ARRANGEMENTS are being made for finding capital at

Marylebone to continue hiring out apparatus; electrical fittings are required by the Brighton and West Ham Guardians; quantities of telephone apparatus in Australia; and electricity generating plant at Manchester and Aberdeen (p. 495).

THE Marylebone Electricity Department will not allow more employees to enlist. Practically the whole of the staffs at Bristol and Burnley have attested.—An emergency supply involving a kw. charge of £12,000 has been arranged between the Marylebone Electricity Department and the Central Electric Supply Co.—The question of the excess profits tax in relation to municipal undertakings has been discussed at Manchester (p. 496).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDING.

Drills, 6.25 to 7.25; 7.25 to 8.25 p.m.

(To-day) Thurs., Dec. 9th: Sections I. and II., shooting.

Fri., Dec. 10th: Sections III. and IV., technical. Sections I. and II., squad. Signalling section and recruits.

Sat., Dec. 11th: Instruction class at 2.30 p.m.

Mon., Dec. 13th: Sections I. and II., technical. Sections III. and IV., squad. Signalling sections and recruits.

Tues., Dec. 14th: School of Arms with Architects Corps, 6.0 to 8.0 p.m.

Thurs., Dec. 16th: Sections III. and IV., shooting.

Fri., Dec. 17th: Sections III. and IV., technical. Sections I. and II., squad. Signalling sections and recruits.

Sat., Dec. 18th: Uniform parade. Time and place to be posted at headquarters later.

Sun., Dec. 19th: Trench digging for Sections I. and II. Parade at Victoria Station—time to be announced later.

Sections for technical parade at Headquarters, London Electrical Engineers, 46 Regency Street, S.W.

Sections for shooting parade at miniature ranges.

Unless otherwise ordered, all parades at Chester House.

(For "Arrangements for the Week" see p. 496.)

SUBSCRIPTION RATES.

The postage on ELECTRICAL ENGINEERING is unaffected by the new postal regulations, and the subscription for the United Kingdom is as hitherto, 6s. 6d. per annum, post free.

REDUCED SUBSCRIPTION RATES FOR COLONIES AND ABROAD.

The subscription in future will be 8s. 6d. per annum, post free, instead of 13s. All subscriptions are payable in advance.

Orders should be addressed to and cheques made payable to—

Temple Chambers, London, E.C.

ELECTRICAL ACCIDENTS IN POWER STATIONS AND FACTORIES

(Concluded from p. 479.)

AMONGST the electric shock accidents there were several cases where the victim was brought round by means of artificial respiration. On the other hand, in several of the cases which ended fatally no adequate measures were taken to attempt to restore animation. In one case the patient was sent on an ambulance to the hospital, where the doctor pronounced him dead. At the inquest the doctor stated that as he was informed that the man had received a 5,000 volt shock it would have been of no use if artificial respiration had been carried out in the first instance. In another case (440 volts 3-phase) artificial respiration was started by the employees. Fifteen minutes after the accident a doctor arrived and pronounced the victim dead, and no further efforts at resuscitation were made. In another case (200 volts 2-phase) artificial respiration was conducted until a doctor ten minutes afterwards pronounced life extinct, and no further efforts were made. Similarly in two other cases efforts were abandoned after 25 and 30 minutes respectively on the doctor pronouncing the patient dead. Two years ago attention was drawn to a letter by Dr. Reginald Morton, which appeared in the *Lancet* and other papers, pointing out that death from electric shock is in general at first only apparent, and that by means of artificial respiration promptly and carefully carried out patients may often be revived, even as long as two hours from the time of the accident. In general, however, says Mr. Ram, the medical profession appears to be somewhat ignorant on this matter, with the result that in many cases adequate efforts at resuscitation are not carried out.

TABLE III.—SHOWING VOLTAGE AND SYSTEM IN FATAL CASES.

| Number of Fatalities. | Voltage of System. | Voltage of Circuit or Probable Voltage of Shock. | System. |

| 1‡ | 200 | 200 | 2-phase. |

20

It will be noticed that all the fatalities were due to shock from alternating current; 18 were due directly to shock and two to fall following shock. 15 were from pressures of 440 volts or less. Most of the shocks being to earth from touching one conductor only of the system, the voltage received by the victim was less than the voltage between phases.

In his visits during the year Mr. Ram again found numerous examples of dangerous switch gear and other apparatus contravening the requirements of the Regulations. In high pressure and extra high pressure stations switchboards without any protection of conductors within easy reach of persons in the passage-ways were noted. In one case there were bare conductors at 10,000 volts along one wall with a gangway about three feet wide, a single iron rail 12 inches out was all the protection. At the far end there were isolating switches requiring to be operated at intervals of a few days, necessitating the use of the passage while the conductors were live. In another case, although the passage was wider, there was not even a hand rail. The excuse sometimes offered is that only authorised persons are allowed in the passage-ways. When an accident happens to the authorised person and experience shows that such persons are by no means immune, he is blamed for not having been more careful. In one case such a passage-way was also used as a store room. Sometimes where bus-bars and isolating switches are placed out of reach from the floor, lamps for lighting the passage-ways are placed close to them, so that when a lamp fails and requires renewing the attendant will have to get up dangerously close to the live conductors. In some cases where the protection was adequate as regards ordinary routine operations and inspection, and where duplicate bus-bars were provided, the arrangement was such that when cleaning or other work should have to be done the advantage of the duplicate bars was lost. Thus the generator and feeder cells were arranged for connecting to either set of bus-bars by selector switches. Both sets of selector switches were, however, in the same compartment, and the two sets of bus-bars were not separated, so that when it should become necessary to clean the insulators of the isolating switches or bus-bars or otherwise work upon them, it would be necessary to shut down on both sets and therefore to stop the supply. This point has been

overlooked in a number of public supply stations from which the supply is supposed to be continuous. In some cases a still more obvious mistake has been made in putting the isolating switches in the same compartment with the oil switches, so that unless special screens are provided for covering up the live side of the isolating switches, which is not always practicable, an oil switch cannot be overhauled without shutting down the whole switchboard. On a 2,000 volt direct current switchboard there were double pole switches having exposed blades five inches apart with the handle arranged as a cross piece between. Although there was a flange at each end of the handle, the arrangement was obviously very dangerous.

Further examples of medium pressure 3-phase switchboards, mostly with oil switches, were found on works where the supply has to be maintained continuously, including night time and Sundays, and where no provision was made for isolating the oil switches or other parts when any work should become necessary. On some switchboards, fuses, even for main circuits, were placed at the back in positions (e.g., between the bus-bars and the slate panels) where they could not be reached without danger. On a 550 volt switchboard having three rows of double pole switches, the switches of the lower rows were arranged so that their handles came between the blades of the switches in the row above. In a works using large electric welders, the primary switchboards, 440 volts alternating, having bare switches, fuses, &c., were placed behind the welders where they could only be reached by standing on the welding machines, and where the metal hoops being handled would be liable to be accidentally brought into contact with them. At a large new dock the cranes had bare switchboards in the confined space of the driving cabins. The connector plugs for the main cables to the cranes were not protected by switches, and were so designed as to be liable to short circuit on plugging in. The most common faults in works concern the distribution fuse boards. Fuse-holders which cannot be handled without risk of touching live metal, and in which the fuse wires are unprotected, are still supplied for new installations. In one 400 volt 3-phase installation cartridge fuses with thumb-screw terminals were found in iron cabinets and over non-insulating floors. In a timber-yard having portable electric saw benches out of doors on a 440 volt 3-phase system, the flexible conductors were not protected by switches and the fuses were of a type dangerous to handle, and the metal saw benches were not earthed.

Mr. Ram's report, of course, is embodied in the annual report of the Chief Inspector of Factories and Workshops, and we refer now to a number of matters mentioned in other parts of the full report which will be of interest to our readers.

Mr. J. H. Rogers, H.M. Superintending Inspector, in the section on sanitation, deals with lighting, the importance of which, both natural and artificial, he points out, is being appreciated more every year. Although the inspectors have at present no statutory power to require a standard of lighting, nevertheless suggestions which they make at their visits are resulting in the remedying of conditions which must have caused injury not only to eyesight, but to general health. Though the more modern works have usually enough lighting, the arrangement of the lights is often bad. Metal filament lamps in clear bulbs are frequently placed too close to the eyes of the workers, and large opaque shades are recommended. It is interesting, in connection with the first report of the Departmental Committee on Lighting (ELECTRICAL ENGINEERING, December 2nd, p. 485), to find it pointed out that very little attention appears to be given to providing good or rather well-arranged artificial lighting, it being largely left to the contractor who puts up the lights to decide the number of points and the proper distribution. Reference is specially made to the defective lighting of grinders' shops in Sheffield, some of which are very gloomy places.

In connection with the disposal of dust and fumes collected by fans in town factories, Mr. Harston, reporting from Birmingham, suggests that Sir Oliver Lodge's idea of thirty years ago of depositing fumes and dust by means of electricity might be revived now that there are convenient means of producing the high-tension current needed, and that the problems of adequate insulation and other difficulties have now been more or less solved. He mentions that a system based upon this is in use in America in many factories, but doubts if the process could be employed with advantage where carbonaceous dusts are dealt with.

Overhead electric cranes have been responsible for a number of fatal and serious accidents, but largely from mechanical causes.

With regard to the electric accumulator industry, several new factories have been built on modern lines, whilst older ones have been reconstructed and much improved. The irregularities during the year were chiefly due to lack of maintenance of washing conveniences, inefficient exhaust draught at lead melting-pots, due to faulty construction of ducts, and at the filling, filing, and brushing benches. In one works a new device consisting of a combined mixing and pasting machine has been introduced which is said to work satisfactorily. In consequence of cases of lead-poisoning to men engaged at a machine for pressing plates filled with paste a system of exhaust ventilation has been tried. This, however, is a difficult matter, as

* Shock from neutral conductor. † 1 fall due to shock. ‡ 1 fall due to shock.

the exhaust has to be arranged near the edge of the press bed plate, the only place where dust could escape, but the difficulties are being overcome. Perforated grids over water trays to catch the heavier particles of lead, and exhaust hoods to deal with the dust, have been installed in several works at the filing and brushing benches. The number of lead poisoning cases in the electric accumulator works was 41, as compared with 44 in the previous year. There was, however, no death from this cause.

THE INSTITUTION ROLL OF HONOUR

WE have from time to time recorded the names of members of the Institution of Electrical Engineers who have lost their lives in the service of their country. The last Journal of the Institution, however, gives a full list compiled to November 20th. We give this below:—

MEMBERS: *Killed in Action.*—Capt. W. Casson, 7th London Regt.; Capt. E. G. Tidd, 6th Highland Light Infantry.

Killed.—Capt. G. L. Slater, R.N., H.M.S. *Bulwark*.

ASSOCIATE MEMBERS: *Killed in Action.*—Lieut. A. W. Brydon, 2/4th Queen's Royal West Surrey Regt.; Sub-Lieut. W. J. Henry, Anson Batt., R.N.D.; H. Labour, French Army; Private N. V. Lloyd, 6th Manchester Regt.; Major Marsh, H.H.S., 2nd London Divisional R.E.; 2nd Lieut. J. L. Moffet, 3rd Royal Scots Fusiliers; Capt. V. W. Newman, Loyal North Lancs. Regt.

Died of Wounds.—Private A. M. Doig, 6th Manchester Regt.; Private J. Gilbert, 6th Manchester Regt.; Corporal R. P. Hulton, Divisional Engineers, R.N.D.; Lance-Corpl. A. H. Read, Divisional Engineers, R.N.D.; Sapper F. E. Tilley, Divisional Engineers, R.N.D.; 2nd Lieut. W. Winkworth, 5th Northumberland Fusiliers.

ASSOCIATE: *Killed in Action.*—Major A. Gardiner, Royal Engineers.

GRADUATE: *Died of Wounds.*—Sapper P. A. E. Warburton, New Zealand Engineers.

STUDENTS: *Killed in Action.*—2nd Lieut. H. G. Byng, 2nd Border Regt.; 2nd Lieut. S. Gudgeon, 3rd Manchester Regt.; Lance-Corporal C. W. Miller, 6th Manchester Regt.; Private E. C. H. Slater, 6th Manchester Regt.; 2nd Lieut. E. W. Wilson, West Yorkshire Regt.; 2nd Lieut. A. Y. Young, 2nd Royal Scots Fusiliers.

Died of Wounds.—Sapper A. H. Ogden, Divisional Engineers, R.N.D.; 2nd Lieut. E. Swinton, Royal Field Artillery.

Died.—Sapper J. A. Donald, Divisional Engineers, R.N.D.; Trumpeter N. V. Foote, 2nd Australian Light Horse; Sapper W. W. Pullen, Divisional Engineers, R.N.D.; Sapper H. Woodside, Divisional Engineers, R.N.D.

The Institution and Research.—The last issue of the *Journal of the Institution of Electrical Engineers* states that the Council have made application for a grant under the Government scheme for the organisation and development of industrial research. On September 7th Sir John Snell and Dr. S. P. Thompson, F.R.S., on behalf of the Research Committee, had an interview with Sir William McCormick, Chairman of the Research Advisory Council which has been appointed by the Board of Education to deal with this matter. The views of the Research Committee were given at the interview, together with a statement of the researches in hand or decided upon. A letter has since been received from the Research Advisory Council asking the Research Committee to submit schedules of particulars of the above-mentioned researches, with notes of the grants desired for each by the Institution, &c. This information has been furnished.

The Council have approved a report of the Research and Wiring Rules Committees urging the desirability of carrying out an investigation into the mechanical and physical properties of rubber considered as an insulating material, and they have included it in the list of researches for which a grant is being sought from the Research Advisory Council of the Board of Education.

Million-volt Transformer.—A transformer has been constructed for the Panama-Pacific International Exposition at San Francisco to give a million volts at its high-tension terminals. Some particulars of this transformer are given in the "American Electrical Review." It is designed to develop 1,000kw. at 60 cycles per sec. The primary receives its supply at 2,200 volts. A special building, with the appearance of a Zeppelin hangar, has been erected to house it, both ends of the building being open to give clearance to the H.T. wires passing out. There are no nails in the building, which is held together by iron bolts running parallel to the H.T. wires "to avoid the danger of fire from static stress." The transformer is placed in a metal lined cement tank containing 225 barrels of high-grade insulating oil. The secondary winding consists of 190 coils of aluminium strip in series, one end being earthed. The weight of the transformer is about 30,000 lb.

A TUNGSTEN ARC LAMP

AFTER carbon had been regarded for many years as the only material for filaments of incandescent lamps, it was superseded by the metal tungsten, and the efficiency of the lamp was improved three-fold. While it is too soon to prophesy a similar development in arc lamps, yet the first step has been taken, and a lamp has been successfully developed at the Ediswan laboratory at Ponders End in which the source of light is an arc between tungsten electrodes. In spite of the enormous increase in the value of carbons since the outbreak of the war, tungsten is still the more precious material, and it would, of course, be out of the question to burn the metal away in the atmosphere in an open arc. The arc therefore burns in an inert gas, such as nitrogen or argon, and the lamp is contained in a glass bulb of the same shape and size as that of an incandescent lamp.

An ingenious method is employed to strike the arc. To employ in a closed incandescent lamp bulb an ordinary arc lamp series coil and electromagnetic mechanism would be hardly feasible, and it was found that a thermal expansion strip made up of two metals with different coefficients of expansion did not move with sufficient speed to prevent the electrodes sticking together or spluttering. An incandescent filament, especially if, instead of being of pure tungsten, it is composed of that metal in combination with refractory oxides, such as zirconia, yttria, or thoria, has powerful ionising properties, and such a filament is employed to ionise the gas in the gap between the electrodes, so that the arc can strike across.

Fig. 1 shows (diagrammatically) a lamp constructed on this principle. The positive lead is connected to the tungsten electrode E through a steady resistance and a relay, C. Before the lamp is switched on, the secondary contacts of this relay are closed, and a current passes through the ionising filament B B'. This ionises the gas around E, and a small current passes from E to the ioniser and back to the negative pole; this current gradually increases until the cut-out relay is operated, breaking the ioniser circuit, and "striking" the arc. The sequence of operations is not quite complete at this point, as, if the arc remained at the same part of the filament at which

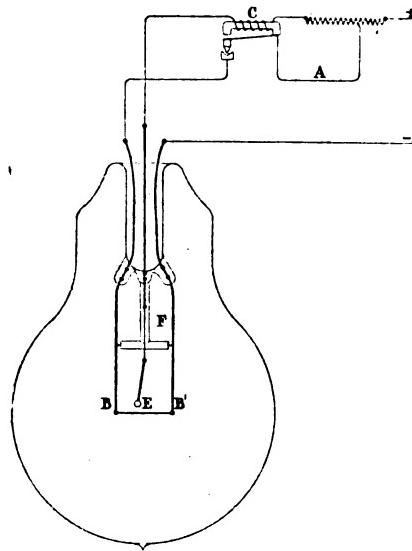

FIG. 1.

the arc was struck, it would soon destroy the ionising properties of the filament. The expansion strip F is therefore retained, and, as it is warmed by the heat rising from the arc, it warps and moves the electrode E to another position on the filament. In this lamp practically the whole of the intense white light emanates from the small globule of tungsten E, about one-tenth of an inch in diameter.

For lamps of larger candle-power, the expansion strip is dispensed with, the filament is placed vertically, and the electrode is in the form of a small plate, the edge of which faces the filament. After the arc strikes, it rises to the upper part of the filament, which is closer to the plate and thickened. In another method there is a fourth lead through the stem of the lamp, holding a smaller electrode fixed between the positive plate

ELECTRICAL ACCIDENTS IN POWER STATIONS AND FACTORIES

(Concluded from p. 479.)

AMONGST the electric shock accidents there were several cases where the victim was brought round by means of artificial respiration. On the other hand, in several of the cases which ended fatally no adequate measures were taken to attempt to restore animation. In one case the patient was sent on an ambulance to the hospital, where the doctor pronounced him dead. At the inquest the doctor stated that as he was informed that the man had received a 5,000 volt shock it would have been of no use if artificial respiration had been carried out in the first instance. In another case (440 volts 3-phase) artificial respiration was started by the employees. Fifteen minutes after the accident a doctor arrived and pronounced the victim dead, and no further efforts at resuscitation were made. In another case (200 volts 2-phase) artificial respiration was conducted until a doctor ten minutes afterwards pronounced life extinct, and no further efforts were made. Similarly in two other cases efforts were abandoned after 25 and 30 minutes respectively on the doctor pronouncing the patient dead. Two years ago attention was drawn to a letter by Dr. Reginald Morton, which appeared in the *Lancet* and other papers, pointing out that death from electric shock is in general at first only apparent, and that by means of artificial respiration promptly and carefully carried out patients may often be revived, even as long as two hours from the time of the accident. In general, however, says Mr. Ram, the medical profession appears to be somewhat ignorant on this matter, with the result that in many cases adequate efforts at resuscitation are not carried out.

It will be noticed that all the fatalities were due to shock from alternating current; 18 were due directly to shock and two to fall following shock. 15 were from pressures of 440 volts or less. Most of the shocks being to earth from touching one conductor only of the system, the voltage received by the victim was less than the voltage between phases.

In his visits during the year Mr. Ram again found numerous examples of dangerous switch gear and other apparatus contravening the requirements of the Regulations. In high pressure and extra high pressure stations switchboards without any protection of conductors within easy reach of persons in the passage-ways were noted. In one case there were bare conductors at 10,000 volts along one wall with a gangway about three feet wide, a single iron rail 12 inches out was all the protection. At the far end there were isolating switches requiring to be operated at intervals of a few days, necessitating the use of the passage while the conductors were live. In another case, although the passage was wider, there was not even a hand rail. The excuse sometimes offered is that only authorised persons are allowed in the passage-ways. When an accident happens to the authorised person and experience shows that such persons are by no means immune, he is blamed for not having been more careful. In one case such a passage-way was also used as a store room. Sometimes where bus-bars and isolating switches are placed out of reach from the floor, lamps for lighting the passage-ways are placed close to them, so that when a lamp fails and requires renewing the attendant will have to get up dangerously close to the live conductors. In some cases where the protection was adequate as regards ordinary routine operations and inspection, and where duplicate bus-bars were provided, the arrangement was such that when cleaning or other work should have to be done the advantage of the duplicate bars was lost. Thus the generator and feeder cells were arranged for connecting to either set of bus-bars by selector switches. Both sets of selector switches were, however, in the same compartment, and the two sets of bus-bars were not separated, so that when it should become necessary to clean the insulators of the isolating switches or bus-bars or otherwise work upon them, it would be necessary to shut down on both sets and therefore to stop the supply. This point has been

overlooked in a number of public supply stations from which the supply is supposed to be continuous. In some cases a still more obvious mistake has been made in putting the isolating switches in the same compartment with the oil switches, so that unless special screens are provided for covering up the live side of the isolating switches, which is not always practicable, an oil switch cannot be overhauled without shutting down the whole switchboard. On a 2,000 volt direct current switchboard there were double pole switches having exposed blades five inches apart with the handle arranged as a cross piece between. Although there was a flange at each end of the handle, the arrangement was obviously very dangerous.

Further examples of medium pressure 3-phase switchboards, mostly with oil switches, were found on works where the supply has to be maintained continuously, including night time and Sundays, and where no provision was made for isolating the oil switches or other parts when any work should become necessary. On some switchboards, fuses, even for main circuits, were placed at the back in positions (e.g., between the bus-bars and the slate panels) where they could not be reached without danger. On a 550 volt switchboard having three rows of double pole switches, the switches of the lower rows were arranged so that their handles came between the blades of the switches in the row above. In a works using large electric welders, the primary switchboards, 440 volts alternating, having bare switches, fuses, &c., were placed behind the welders where they could only be reached by standing on the welding machines, and where the metal hoops being handled would be liable to be accidentally brought into contact with them. At a large new dock the cranes had bare switchboards in the confined space of the driving cabins. The connector plugs for the main cables to the cranes were not protected by switches, and were so designed as to be liable to short circuit on plugging in. The most common faults in works concern the distribution fuse boards. Fuse-holders which cannot be handled without risk of touching live metal, and in which the fuse wires are unprotected, are still supplied for new installations. In one 400 volt 3-phase installation cartridge fuses with thumb-screw terminals were found in iron cabinets and over non-insulating floors. In a timber-yard having portable electric saw benches out of doors on a 440 volt 3-phase system, the flexible conductors were not protected by switches and the fuses were of a type dangerous to handle, and the metal saw benches were not earthed.

Mr. Ram's report, of course, is embodied in the annual report of the Chief Inspector of Factories and Workshops, and we refer now to a number of matters mentioned in other parts of the full report which will be of interest to our readers.

Mr. J. H. Rogers, H.M. Superintending Inspector, in the section on sanitation, deals with lighting, the importance of which, both natural and artificial, he points out, is being appreciated more every year. Although the inspectors have at present no statutory power to require a standard of lighting, nevertheless suggestions which they make at their visits are resulting in the remedying of conditions which must have caused injury not only to eyesight, but to general health. Though the more modern works have usually enough lighting, the arrangement of the lights is often bad. Metal filament lamps in clear bulbs are frequently placed too close to the eyes of the workers, and large opaque shades are recommended. It is interesting, in connection with the first report of the Departmental Committee on Lighting (ELECTRICAL ENGINEERING, December 2nd, p. 485), to find it pointed out that very little attention appears to be given to providing good or rather well-arranged artificial lighting, it being largely left to the contractor who puts up the lights to decide the number of points and the proper distribution. Reference is specially made to the defective lighting of grinders' shops in Sheffield, some of which are very gloomy places.

In connection with the disposal of dust and fumes collected by fans in town factories, Mr. Harston, reporting from Birmingham, suggests that Sir Oliver Lodge's idea of thirty years ago of depositing fumes and dust by means of electricity might be revived now that there are convenient means of producing the high-tension current needed, and that the problems of adequate insulation and other difficulties have now been more or less solved. He mentions that a system based upon this is in use in America in many factories, but doubts if the process could be employed with advantage where carbonaceous dusts are dealt with.

Overhead electric cranes have been responsible for a number of fatal and serious accidents, but largely from mechanical causes.

With regard to the electric accumulator industry, several new factories have been built on modern lines, whilst older ones have been reconstructed and much improved. The irregularities during the year were chiefly due to lack of maintenance of washing conveniences, inefficient exhaust draught at lead melting-pots, due to faulty construction of ducts, and at the filling, filing, and brushing benches. In one works a new device consisting of a combined mixing and pasting machine has been introduced which is said to work satisfactorily. In consequence of cases of lead-poisoning to men engaged at a machine for pressing plates filled with paste a system of exhaust ventilation has been tried. This, however, is a difficult matter, as

* Shock from neutral conductor. † 1 fall due to shock. ‡ 1 fall due to shock.

the exhaust has to be arranged near the edge of the press bed plate, the only place where dust could escape, but the difficulties are being overcome. Perforated grids over water trays to catch the heavier particles of lead, and exhaust hoods to deal with the dust, have been installed in several works at the filing and brushing benches. The number of lead poisoning cases in the electric accumulator works was 41, as compared with 44 in the previous year. There was, however, no death from this cause.

THE INSTITUTION ROLL OF HONOUR

WE have from time to time recorded the names of members of the Institution of Electrical Engineers who have lost their lives in the service of their country. The last Journal of the Institution, however, gives a full list compiled to November 20th. We give this below:-

MEMBERS: *Killed in Action.*—Capt. W. Casson, 7th London Regt.; Capt. E. G. Tidd, 6th Highland Light Infantry.

Killed.—Capt. G. L. Sclater, R.N., H.M.S. *Bulwark*.

ASSOCIATE MEMBERS: *Killed in Action.*—Lieut. A. W. Brydon, 2/4th Queen's Royal West Surrey Regt.; Sub-Lieut. W. J. Henry, Anson Batt., R.N.D.; H. Labour, French Army; Private N. V. Lloyd, 6th Manchester Regt.; Major Marsh, H.H.S., 2nd London Divisional R.E.; 2nd Lieut. J. L. Moffet, 3rd Royal Scots Fusiliers; Capt. V. W. Newman, Loyall North Lancs. Regt.

Died of Wounds.—Private A. M. Doig, 6th Manchester Regt.; Private J. Gilbert, 6th Manchester Regt.; Corporal R. P. Hulton, Divisional Engineers, R.N.D.; Lance-Corpl. A. H. Read, Divisional Engineers, R.N.D.; Sapper F. E. Tilley, Divisional Engineers, R.N.D.; 2nd Lieut. W. Winkworth, 5th Northumberland Fusiliers.

ASSOCIATE: *Killed in Action.*—Major A. Gardiner, Royal Engineers.

GRADUATE: *Died of Wounds.*—Sapper P. A. E. Warburton, New Zealand Engineers.

STUDENTS: *Killed in Action.*—2nd Lieut. H. G. Byng, 2nd Border Regt.; 2nd Lieut. S. Gudgeon, 3rd Manchester Regt.; Lance-Corporal C. W. Miller, 6th Manchester Regt.; Private E. C. H. Slater, 6th Manchester Regt.; 2nd Lieut. E. W. Wilson, West Yorkshire Regt.; 2nd Lieut. A. Y. Young, 2nd Royal Scots Fusiliers.

Died of Wounds.—Sapper A. H. Ogden, Divisional Engineers, R.N.D.; 2nd Lieut. E. Swinton, Royal Field Artillery.

Died.—Sapper J. A. Donald, Divisional Engineers, R.N.D.; Trumpeter N. V. Foote, 2nd Australian Light Horse; Sapper W. W. Pullen, Divisional Engineers, R.N.D.; Sapper H. Woodside, Divisional Engineers, R.N.D.

The Institution and Research.—The last issue of the *Journal* of the Institution of Electrical Engineers states that the Council have made application for a grant under the Government scheme for the organisation and development of industrial research. On September 7th Sir John Snell and Dr. S. P. Thompson, F.R.S., on behalf of the Research Committee, had an interview with Sir William McCormick, Chairman of the Research Advisory Council which has been appointed by the Board of Education to deal with this matter. The views of the Research Committee were given at the interview, together with a statement of the researches in hand or decided upon. A letter has since been received from the Research Advisory Council asking the Research Committee to submit schedules of particulars of the above-mentioned researches, with notes of the grants desired for each by the Institution, &c. This information has been furnished.

The Council have approved a report of the Research and Wiring Rules Committees urging the desirability of carrying out an investigation into the mechanical and physical properties of rubber considered as an insulating material, and they have included it in the list of researches for which a grant is being sought from the Research Advisory Council of the Board of Education.

Million-volt Transformer.—A transformer has been constructed for the Panama-Pacific International Exposition at San Francisco to give a million volts at its high-tension terminals. Some particulars of this transformer are given in the "American Electrical Review." It is designed to develop 1,000kw. at 60 cycles per sec. The primary receives its supply at 2,200 volts. A special building, with the appearance of a Zeppelin hangar, has been erected to house it, both ends of the building being open to give clearance to the H.T. wires passing out. There are no nails in the building, which is held together by iron bolts running parallel to the H.T. wires "to avoid the danger of fire from static stress." The transformer is placed in a metal lined cement tank containing 225 barrels of high-grade insulating oil. The secondary winding consists of 190 coils of aluminium strip in series, one end being earthed. The weight of the transformer is about 30,000 lb.

A TUNGSTEN ARC LAMP

AFTER carbon had been regarded for many years as the only material for filaments of incandescent lamps, it was superseded by the metal tungsten, and the efficiency of the lamp was improved three-fold. While it is too soon to prophesy a similar development in arc lamps, yet the first step has been taken, and a lamp has been successfully developed at the Ediswan laboratory at Ponders End in which the source of light is an arc between tungsten electrodes. In spite of the enormous increase in the value of carbons since the outbreak of the war, tungsten is still the more precious material, and it would, of course, be out of the question to burn the metal away in the atmosphere in an open arc. The arc therefore burns in an inert gas, such as nitrogen or argon, and the lamp is contained in a glass bulb of the same shape and size as that of an incandescent lamp.

An ingenious method is employed to strike the arc. To employ in a closed incandescent lamp bulb an ordinary arc lamp series coil and electromagnetic mechanism would be hardly feasible, and it was found that a thermal expansion strip made up of two metals with different coefficients of expansion did not move with sufficient speed to prevent the electrodes sticking together or spluttering. An incandescent filament, especially if, instead of being of pure tungsten, it is composed of that metal in combination with refractory oxides, such as zirconia, yttria, or thoria, has powerful ionising properties, and such a filament is employed to ionise the gas in the gap between the electrodes, so that the arc can strike across.

Fig. 1 shows (diagrammatically) a lamp constructed on this principle. The positive lead is connected to the tungsten electrode E through a steady resistance and a relay, C. Before the lamp is switched on, the secondary contacts of this relay are closed, and a current passes through the ionising filament B B'. This ionises the gas around E, and a small current passes from E to the ioniser and back to the negative pole; this current gradually increases until the cut-out relay is operated, breaking the ioniser circuit, and "striking" the arc. The sequence of operations is not quite complete at this point, as, if the arc remained at the same part of the filament at which

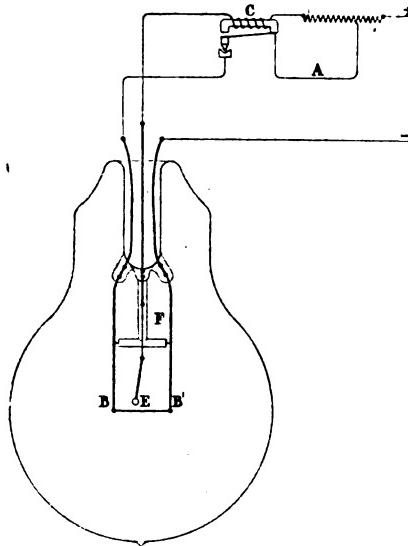

FIG. 1.

the arc was struck, it would soon destroy the ionising properties of the filament. The expansion strip F is therefore retained, and, as it is warmed by the heat rising from the arc, it warps and moves the electrode E to another position on the filament. In this lamp practically the whole of the intense white light emanates from the small globule of tungsten E, about one-tenth of an inch in diameter.

For lamps of larger candle-power, the expansion strip is dispensed with, the filament is placed vertically, and the electrode is in the form of a small plate, the edge of which faces the filament. After the arc strikes, it rises to the upper part of the filament, which is closer to the plate and thickened. In another method there is a fourth lead through the stem of the lamp, holding a smaller electrode fixed between the positive plate

and the filament, and situated at a definite distance from the former. By the operation of change-over switches in the circuit an arc is first struck between the filament as cathode and the small electrode as anode. On this electrode becoming brightly incandescent the change-over switch quickly operates, and brings into the circuit the large plate electrode, at the same time breaking the negative connection to the filament and changing the polarity of the small white-hot electrode. This latter now being negative, an arc is immediately formed between it and the large positive plate. This arrangement enables electrodes of any size to be used, and the filament being out of the circuit is completely protected.

A flat electrode is also employed. To obtain the best results a definite relation of surface to volume must be maintained. This type of lamp is made in sizes of 500 to 1,000 candle-power, the maximum intensity being given in a direction at right angles to the plane of the electrode.

In the same way that a carbon lamp appears yellow in comparison with the ordinary half-watt lamp, so does the latter appear yellow when contrasted with the new incandescent arc. For high candle-power lamps the bulbs are much smaller than for metal-filament lamps of corresponding candle-power, e.g., electrodes to give 500 candle-power can be placed with safety in a bulb 4 in. in diameter.

Curve A (Fig. 2) shows the percentage variation of pressure with current. As will be seen, the curve is similar to that for an ordinary carbon arc, though showing greater stability. The pressure across the arc steadily decreases with an increase of current, and if continued until the sputtering point is reached, the pressure suddenly drops.

A representative efficiency curve is given by B in Fig. 2, which shows the efficiency for the normal working current to

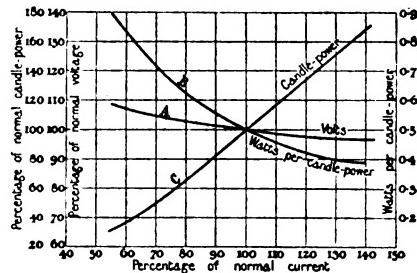

FIG. II.

be about 0.5 watt per International candle-power, or 2 candle-power per watt. The current may be increased until the tungsten reaches the sputtering point, at which the efficiency is about 0.3 watt per candle-power or 3.33 candle-power per watt.

Curve C in Fig. 2 shows the variation of candle-power with current.

Lamps have been made with a life of 500 hours, and it is hoped that further experiment will make it possible to obtain a true half-watt lamp with a life of 800 hours. During life the average decrease in candle-power is about 10 per cent. Some experiments to determine the effect of varying the pressure across the supply mains showed the arc to be very stable. A voltage drop of 20 per cent. in the case of the small lamps, and 25 per cent. in the larger sizes, was necessary before the arc was extinguished.

As compared with the carbon-filament lamp (3.5 watts per candle-power) with an intrinsic brilliancy of about 375 candle-power per sq. in., and metal-filament lamps giving 1,000 candle-power per sq. in., the intrinsic brilliancy of the new lamp at an efficiency of 0.5 watt per candle-power, or 2 candle-power per watt, is approximately 10,000 candle-power per sq. in. The colour of the light can be made to vary from a bright yellow when running at low efficiencies, to a very intense white light when the lamp is run to the sputtering point of the electrodes. The range of intrinsic brilliancy between these limits is approximately 400 to 30,000 candle-power per sq. in.

The above descriptive particulars of the new lamp, which, we understand, may very shortly be placed upon the market, are taken from a very modest Paper by E. A. Gingham and S. R. Mullard, printed in the number of the *Journal of the Institution of Electrical Engineers* just issued.* The Paper also contains some interesting photographs comparing the spectrum of this lamp with those of others. It is evident that the light is almost perfectly white, that it extends further at the

red end of the spectrum than the 1½-watt tungsten lamp, and does not show the same weakness in green rays. It should therefore be excellent for colour-matching. Moreover, it extends far into the ultra-violet, and should be useful for photographic purposes. The main utility for special purposes will be, however, for projection work—both for ordinary lanterns and cinematographs. The makers are also developing an examination lantern for surgical purposes, which should ultimately displace the troublesome Nernst lamp, hitherto the most popular for this, but practically unobtainable since the outbreak of the war. A range of candle-power from 200 to 2,000 is contemplated, so that, as soon as circumstances permit its more complete development, it should have a large applicability for general purposes as well as the special uses mentioned.

CORRESPONDENCE

THE INSTITUTION AND ALIEN ENEMY MEMBERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Many members of the I.E.E. consider that the Council should be approached with a view to removing from the list of membership those individuals who are alien enemies.

My own opinion is that the members of the I.E.E. should prepare their protest outside the Institution, and, if they feel justified, present it to the Council. I should be pleased to hear from any members sharing my views with the object of taking speedy action.

Yours, etc.,
W. ELLERD-STYLES.

Grafton House, Golden Square, W..
Dec. 7th, 1915.

Obituary: Thomas Parker.—By the death of Mr. Thomas Parker at his home at Ironbridge, Shropshire, on Sunday, at the age of 72, another of the founders of the electrical industry in this country has passed away. He was one of the first to show the incandescent lamp here in 1882, and about the same time took up, in conjunction with Elwell, a patent for the manufacture of accumulators. This partnership with Elwell developed into a business for the manufacture of electrical machinery generally, the firm subsequently being changed into the Electric Construction Co. Mr. Parker was responsible for the lay-out of the original works on the present site at Bushbury. He left this concern in 1894, and founded Thos. Parker, Ltd., at Wolverhampton, which achieved a high reputation as manufacturers of electrical machinery. When in turn he retired from this undertaking (now Reed Roturbo, Ltd.), Mr. Parker entered into private consulting work. In addition to his manufacturing interests, Mr. Parker was responsible for many of the original lighting and traction systems in this country. He also sat with Dr. H. F. Parshall as one of the umpires (with the late Hon. Alfred Lyttelton as arbitrator) to determine the system of electric traction to be adopted by the Inner Circle Railway in London. At that time there had been much controversy as to the merits of the 600-volt continuous-current third-rail system, which Dr. Parshall may be said to have represented, and the high-tension overhead three-phase system, then being developed by Messrs. Ganz & Co., of Budapest, the use of which Mr. Parker advocated.

Foreign-owned Companies.—The position of companies in this country owned or mainly owned by enemies has recently been the subject of renewed discussion in various parts of the country, and a question on the matter was put to the Government in the House of Commons on Monday. It was stated in reply, however, that the present position of these companies—namely, that being registered in this country they have all the privileges of English companies, with the proviso that no profits are to be paid over to enemy shareholders during the war—will continue for the present, but that consideration is being given to the question whether any steps shall be taken after the war to prevent the registration of companies the majority of whose shares are under foreign control.

Women Electricians.—At a meeting of the Liverpool branch of the Electrical Contractors' Association last week, a discussion took place as to the steps to be taken to fill the deficiency caused by electrical works being engaged on war work. Eventually the following resolution was passed: "That in the opinion of this meeting of the Liverpool branch of the Electrical Contractors' Association it is advisable in the interests of the country that a certain number of women should be trained in various branches of electrical work to ensure that the country's commercial work shall not suffer through the war, and this shall be strictly without prejudice to the electricians who have enlisted. . . ."

* For convenience of readers who are not members of the Institution, we shall be pleased to send copies of this number of the *Journal* to any address in the United Kingdom or abroad post free at the published price of 3s. 6d. The number also contains the full text of Mr. C. P. Sparks Presidential Address (an abstract of which appeared in ELECTRICAL ENGINEERING of Nov. 25th), an excellent photograph portrait of Mr. Sparks and Mr. B. Welburn's Address on the Production and Properties of Electrolytic Copper (briefly reported in our issue of Nov. 1st). Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203, Temple Chambers, London E.C. and should be accompanied by a remittance.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 2nd, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

21,536/14. **Bells.** J. BEIN. A watertight electric bell in which the magnet coils project through the case; the hammer is wholly outside, and the terminals are inside. (Four figures.)

22,551/14. **Metal Filaments.** E. R. GROTE and W. H. REYNOLDS. A binder for making tungsten filaments by the squirting process, consisting of gelatinous aluminium hydrate in conjunction with a solution of tungstic acid or other tungsten compound.

22,265/14. **Telegraphy.** MUIRHEAD & CO., LTD., and G. O. SQUIER. A submarine cable telegraph system in which messages are transmitted by an unbroken alternating current, the dots, dashes, and spaces being represented by variations in amplitude of each successive half-wave obtained by introducing resistance or impedance into the cable circuit, under control of a perforated strip. (Five figures.)

2,289/15. **Cables.** W. T. HENLEY'S TELEGRAPH WORKS CO., LTD., and H. SAVAGE. A system of clamping cables with smooth rubber sheathing in fittings, glands, &c., depending upon the provision of a collar or protrusion of tough india-rubber securely united to the sheathing. (One figure.)

3,837/15. **Electromagnetic Switches.** IGRANIC ELECTRIC CO., LTD. (*Cutter Hammer Mfg. Co., U.S.A.*). An electromagnetic switch comprising a movable switch element with mechanical means for latching it in a predetermined position, and an electromagnet having an armature moving the switch to this position when attracted, and another armature to trip the latch, so arranged in the magnetic field that, until the switch armature is attracted, the latching armature cannot be acted upon. (Four figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Arc Lamps: GIMINGHAM [Arc-incandescent lamps] 22,437/14.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: SOC. CERAMICA RICHARD-GINORI [Insulators] 24,631/14; SMITH [Cables] 7,675/15.

DYNAMOS, MOTORS, AND TRANSFORMERS: FOSTER & SHARP [Controlling variable-speed dynamos] 1,474/14; B.T.-H. CO. (G.E. CO., U.S.A.) [Induction motors] 3,502/15.

Electrometallurgy and Electrochemistry: JENKINS, PATTINSON, and WELLESLEY [Electrolytic cells] 22,867/14; BUCHER [Electrical production of cyanides] 23,292/14.

Heating and Cooking: BRITISH ELECTRIC HEATER CO. and KRATT [Sterilisers] 22,720/14; GROGAN [Heating elements] 23,676/14.

Switchgear, Fuses, and Fittings: PICKERINGS, LTD., and FOTHERGILL [Controllers] 24,108/14; HOUGH and HARRISON [Fittings] 2,928/15.

Telephony and Telegraphy: RELAY AUTOMATIC TELEPHONE CO. and AITKEN [Automatic and semi-automatic telephone systems] 22,715/14; AUTOMATIC TELEPHONE MFG. CO. (Automatic Electric Co., U.S.A.) [Telephone hand sets] 23,282/14.

Traction: HUGHES and PAYNE [Train stop] 16,558/14; W. R. SYKES INTERLOCKING SIGNAL CO. and SYKES [Train stop] 22,328/14; MIDGLEY and VANDERVELL [Engine-starters] 7,206/15.

Miscellaneous: MAITRE and MARTIN [Contact-breaker] 7,692/14; GALVANOPHOREN-WERKE (*System Vogt*), S. SZUBERT, KOMMANDITGESELLSCHAFT & VEREINIGTE ELEKTRICITÄTSWERKE, GES. [Condensers] 22,931/14; HARLAND & WOLFF, LTD., and BENTLEY [Steering-gear] 569/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Distribution Systems, Cables, Insulators, &c.: SIMONSEN [Insulators] 15,192/15.

Heating: LANDIS & GYR A.G. [Heating device] 15,685/15.

Miscellaneous: LINCOLN [Indicators] 15,128/15.

Opposition to Grant of Patents

Opposition has been entered to a grant on the following application:—

24,293/14. **Engine Starter.** A. H. MIDGLEY and C. A. VANDERVELL. An electric starter for motor-car engines in which the motor pinion is formed on a nut travelling on its shaft, and moves into mesh with the gear ring on the engine by its screw action, springing back automatically when no torque is being transmitted.

Opposition to the following has been withdrawn:—

16,148/13. **Targets.** J. R. QUAIN. Electrically worked self-indicating moving targets.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

25,175/01. **Railway Signalling.** J. B. STRUHLE. A system of automatic signalling employing alternating currents.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: R. K. GRAY [Cable conductors] 17,283/08.

DYNAMOS, MOTORS and TRANSFORMERS: H. A. MAVOR and MAVOR & COULSON [Ventilating ducts for dynamo armatures and transformers, &c.] 18,343/06.

Storage Batteries: H. C. HUBBELL and H. FULLER [Storage battery plates] 17,331/08.

Switchgear, Fuses and Fittings: A. E. G. [Time switches] 18,486/06.

Traction: A. W. GATTIE and A. G. SEAMAN [Electrical clearing house goods distribution system] 17,344/08.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,472.

When replacing an E.H.T. 3-phase switch (which had accidentally been tripped) it was noticed that the reading on the switch ammeter went up to nearly 20 amps., and then gradually died down to almost zero. The current was switched on to two transformers, a 100 and a 50 k.v.a. respectively. What would cause the momentary excessive rise in current? On another occasion, when switching in, there was no rise whatever on the ammeter beyond the transformer current. Is such a rise in any way bad for the transformer from a practical or theoretical point of view?—H. H.

(Replies must be received not later than first post, Thursday, Dec. 16th.)

ANSWERS TO No. 1,470.

We have occasion to make good welded joints in copper wires of all sizes, from the smallest up to $\frac{1}{8}$ in. square. Would a "welding transformer" be suitable for this? If so, what is the

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

arrangement made for adjusting the current to the right value for various sizes of wire?

The first award (10s.) is given to "L. R." for the following reply:—

The method suggested is quite correct for welding joints in copper wires, and is, in fact, largely used. The process commonly goes by the name of the Thomson process, and the apparatus generally used commercially consists essentially of an alternating-current generator, a welding transformer transforming from about 300 volts to 1 volt, the latter being the voltage of the secondary or welding circuit, and electrical regulating apparatus to control the supply of current. The ends of the secondary, which is practically a solid copper block forming a single turn, are provided with suitable clamps directly mounted thereon. These hold the materials to be welded, and pressure devices enable pieces of metal to be forced together by end-pressure, thus making a butt weld when the requisite temperature is reached.

In moderate size machines the operation of welding is performed by hand, that is to say, the smith operating watches the metal, and when he considers the welding temperature is attained, he applies end-pressure by means of a hydraulic jack, switches off the current from the primary, and removes the article from the clamps for swaging.

In the case of smaller materials, such as wires, an automatic welder is usually employed. The Electric Welding Company market an apparatus for this special purpose, operating on the lines described above. The article is held by the clamps on the ends of the secondary, one clamp always being pressed towards the other by means of a spring. When the metal becomes soft enough at the point of contact, this clamp advances, an automatic trigger switch then comes into action, and cuts off the current from the primary directly a good amount of upset has been obtained. Welding in this way is now used to a large extent even for very small copper wires.

A similar machine is made by the British Insulated & Helsby Cables Co., Ltd., for welding copper wires from the smallest size up to the exact dimension stated, namely, $\frac{1}{8}$ ths of an inch. The alternating-current dynamo used with it generates 100 volts. The switches and regulating arrangements in the primary circuit permit complete and delicate control.

Welds made according to this method are certainly good, their strength being greater than hand-made welds. A slight burr is formed, which is not considered objectionable, but it can readily be removed if necessary.

In some cases a resistance formed in a number of sections is used in the primary circuit for regulating, and again in others a reactive coil is employed which has two windings, so that they can be used separately or joined in series or in parallel. In this way a considerable range is secured, and ensures satisfactory welding even for the smallest wires.

The essentials for successful welding in practice are, that the pressure must be comparatively light, that is, only just sufficient to force the burnt metal out of the weld; the metal must be allowed actually to fuse at the joint, and the current should be cut off the moment the wires are squeezed together at the proper welding temperature.

Variation of the cross-section of the wires changes the power required and the time during which the current is applied.

The following gives an approximation of the figures employed in some cases:—

| Square inch section of copper. | Watts in primary. | Seconds. |
|--------------------------------|-------------------|----------|
| 0·125 | 6,000 | 8 |
| 0·25 | 14,000 | 11 |
| 0·375 | 19,000 | 13 |
| 0·5 | 25,000 | 16 |
| 1 | 49,000 | 23 |

No second award is made.

The Students' Section, I.E.E.—The 1915-16 session of the Students' Section of the Institution of Electrical Engineers will be opened to-night (Thursday) by an address by Mr. J. E. Kingsbury (Hon. Treasurer) on "The Institution." The following Papers have been arranged on Wednesday nights as follows: Dec. 15th, A. G. Ramsey, "The Aluminium Electrolytic Arrester, with an Introduction on Electrical Disturbances"; Feb. 2nd, P. R. Coursey, "The Methods employed for the Wireless Communication of Speech"; Feb. 16th, W. J. Jones, "The X-Ray Tube and Modern Practice"; March 1st, discussion on "Suggested Applications of Science to Warfare"; March 15th, E. T. Driver, "Long-distance Transmission Lines"; March 29th, annual general meeting.

DIESEL ENGINE USERS' ASSOCIATION

AT the November meeting of the Diesel Engine Users' Association, held at the Institution of Electrical Engineers, a number of matters were discussed. The Acting Hon. Secretary reported the names of further undertakings and firms who had joined in the movement to endeavour to obtain more favourable terms from the inland revenue authorities in the matter of the allowance off profits for depreciation of Diesel engine plant before assessment for income-tax purposes. In this connection it was pointed out that the present inadequate allowance of only 5 per cent. on the diminishing or written down value of the plant corresponded to an assumed life of 58 years for Diesel engines if the residual value of the plant at the end of the term was taken to be 5 per cent. of the original value. The allowance of 15 per cent. recommended by the Association as fair and reasonable under the circumstances corresponded to an assumed life of 18 years for the plant.

After a short discussion on the serious increase in the price of fuel oil, the discussion on the subject of cracked and seized pistons was resumed by Mr. J. M. Ferguson. He spoke of the practice and experience of Messrs. Willans & Robinson, Ltd., on these points, and laid stress on the great importance of using metal of the special quality necessary for pistons of Diesel engines. The casting should be carried out in the engine-maker's own foundry, under his direct control and supervision.

Mr. P. H. Smith also spoke, and remarked that the fundamental cause of cracks in Diesel engine pistons is a highly heated core trying to expand, but being restricted in so doing by a comparatively cold and very stiff ring of metal surrounding it. This action being progressive, fractures inevitably occurred. It was noticeable, he said, that Diesel engines working continuously day and night gave very little trouble from cracked pistons as compared with other similar engines working more intermittently. Some makers were endeavouring to find a cast-iron for pistons which would not "grow" on repeated heating and cooling. Such an iron is very pure, high in manganese and low in silicon, but, being mainly of Swedish origin, is practically unobtainable at the present time. At the same time, Mr. Smith did not think that the ultimate solution of the trouble of cracked pistons would be found in the adoption of any particular grade of cast iron. After discussing the two general systems of piston construction which have found favour in the case of larger sizes of pistons—namely, pistons with renewable heads and water-cooled pistons—the speaker described a renewable core in the piston head, devised by himself to overcome the trouble of cracking. In the larger sizes of pistons the difficulty is not only to avoid cracking, but seizure, and, said Mr. Smith, all Diesel-engine pistons exceeding 16 ins. diameter should be water-cooled or oil-cooled if the mean effective pressure is as high as 95 to 100 lb. per sq. in. Other speakers took part in the discussion. The next meeting will be held on December 20th.

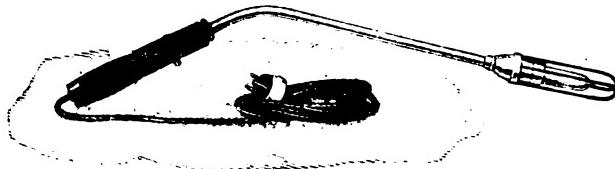

Harmonics in Oscillograms.—A useful contribution to the theory of the operation of the Duddell oscillograph is made by Professor G. W. O. Howe, in a communication published in the I.E.E. Journal. This Paper is the result of an investigation into the accuracy of the amplitude and phase of the ripples in the potential-difference wave of alternators as recorded by the oscillograph. It has been previously shown by the author that the ripples due to the teeth of an alternator should be symmetrical with respect to the fundamental when the machine is on open circuit and there is no dissymmetry in the magnetic field. Many oscillograms, however, showed the ripples to be unsymmetrical, and the question arose as to whether the oscillograph was to blame. Professor Howe shows, by calculation of the magnitude and phase displacement of various harmonics for different degrees of damping, that the change produced mechanically by the oscillograph in the amplitude and phase position is negligible for harmonics of a frequency up to 0·2 of the resonant frequency of the oscillograph, which covers most usual cases in practice.

Shrinking Vectors.—Just as an ordinary alternating current can be represented by a rotating vector of constant length, so a damped oscillation can be represented by a rotating vector of continually diminishing length. A mode of studying damped oscillations by means of "shrinking vectors" is described by Prof. David Robertson in a long communication published in the I.E.E. Journal. The author shows how damped oscillations can be represented by these vectors, and how the equations for such oscillations can be deduced from the vectors almost as easily as those for ordinary alternating currents.

County of London Co.'s War Bulletin.—The second number of the County of London Electric Supply Co.'s War Bulletin gives a list of additional members of the staff who have joined the forces. At the same time we cannot but express regret that the list of those killed in action and wounded increases. The Bulletin is designed to appeal to the staffs, not only of the County of London Electric Supply Co., but its associated companies, the Bournemouth and Poole, the Richmond (Surrey), and the Coatbridge and Airdrie Electric Supply Co. The various letters from the front which are given make most interesting reading.

SIMPLEX SHELL INSPECTION LAMP

THE shell inspection lamp illustrated has been introduced by Simplex Conduits, Ltd. (Garrison Lane, Birmingham). Apart from its robust construction, which makes it particularly suitable for the strenuous usage of munitions factories, it is

provided with an "earth" wire. The lampholder is insulated from the body, and both holder and lamp cap are protected and cannot be touched by the operator as long as the guard is in position. The lamp shown, if used with an "earthing" plug, has the approval of the Home Office.

CATALOGUES, PAMPHLETS, &c., RECEIVED

POPE'S LAMP SHADE.—Pope's Electric Lamp Co., Ltd. (Hythe Road, Willesden, N.W.), is the latest to bring out an advertising lamp shade which will be found useful to those firms wishing to shade their lighting in accordance with the police instructions. A supply of these will be sent to any buyer or seller of electric lamps on application.

STEAM PUMPS.—A pamphlet which will be useful to all users of steam pumps is issued by Willans & Robinson, Ltd. (Rugby), describing Willans-Oddie simplex direct-acting steam pumps. These pumps have the advantageous feature, found in but few other types, that the functions of auxiliary valve, shuttle piston, and main valve are performed by one single piece, and it is claimed that in the Willans-Oddie pump this single combined valve is completely balanced, the unbalanced parts of the valve being exposed to exhaust steam only. A detailed description, with diagrams, of the action of the pump is given, as well as illustrations of pumps for various classes of service, including boiler-feed and hydraulic pumps, air pumps, mine and donkey pumps, forced lubrication pumps, &c., with dimensions, capacities, and code words of standard sizes. A useful section is devoted to notes on the arrangement and fitting up of pumps, setting valve gear, starting up and shutting down, running, replacing of spare parts, of which a list is given, &c. The pamphlet concludes with a table of metric equivalents of the makers' standard pump dimensions.

TENDERS INVITED AND PROSPECTIVE BUSINESS**Generating Stations, Sub-Stations, Mains, &c.**

Aberdeen.—The City Electrical Engineer has presented a report, in which he recommends extensions to the generating plant at an estimated cost of £21,175.

Doncaster.—It is reported that the load on the Balby to Hexthorpe high-tension feeders has reached the limit allowed by the Board of Trade and the question of adding to the capacity is under consideration.

Ilford.—The Electricity Department requires 1,200 yards of conduit. Borough Electrical Engineer. Dec. 15th. (See advertisement on another page.)

London: Islington.—The L.G.B. has approved of the proposal to adapt the present installation at Highgate Hill Infirmary so that current can be taken from the Islington Borough Council as long as the cost does not exceed £500 and is paid for out of revenue.

Marylebone.—The Marylebone Electricity Committee has been considering the steps to be taken so that the Department may be in the financial position to continue the hiring of apparatus to consumers. It is recommended that the Council should advance to the Electricity Committee for twelve months from December 30th the sum of £5,156 for this purpose, interest to be charged at the rate of 5 per cent. per annum, which is now the amount charged by the L.C.C. in respect of municipal loans.

Manchester.—A special report has been prepared dealing with a temporary scheme for increasing the output of electricity pending the completion of the new Barton power station.

Miscellaneous

Australia.—The Deputy Postmaster-General, Melbourne, requires a supply of electrical measuring instruments, telephone parts, and 500 automatic common battery telephones. Further particulars at 72 Victoria Street, S.W. Tenders by Jan. 4th. This information, of course, is only of use to firms who can cable agents.

Brighton.—A supply of electrical fittings for the Guardians. Dec. 14th. Clerk, Princes Street.

Durban.—The Telephone Department of the Corporation requires telephone apparatus and materials and underground telephone cables. Particulars from Messrs. Webster, Steel & Co., 5 East India Avenue, E.C., by whom tenders will be received up to Dec. 31st.

West Ham.—Three months' supply of electrical fittings for the Guardians. Dec. 16th. Clerk, Union Road, Leytonstone, N.E.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £97 10s. to £98 10s. (last week, £98 10s. to £99 10s.).

Agencies.—H.M. Trade Commissioner in Australia reports that a Sydney agent wishes to represent United Kingdom manufacturers of electrical machinery and apparatus, particularly wire-drawn lamps. Further particulars at 73 Basinghall Street, E.C.

APPOINTMENTS AND PERSONAL NOTES

Alderman Duncan Watson has been re-appointed Chairman of the Marylebone Electric Supply Committee.

The Generating Station Engineer at Marylebone, Mr. T. K. Richardson, being absent on sick leave, Mr. Leonard, Chief Station Assistant, has been appointed to carry out the duties with a temporary increase in his salary to £350 per annum.

During the absence of Mr. Harold Gray, the Borough Electrical Engineer, who is serving with the Accrington and Burnley Howitzer Brigade, the Acting Engineer is to be paid an extra remuneration of £100 per annum from the date of Mr. Gray's enlistment.

Mr. M'Kee, Distributing Engineer in the Belfast Electricity Department, has resigned.

A Works Manager is required for a motor and electrical engineering factory in the Midlands. (See advertisement on another page.)

The Royal Holloway College requires a Resident Engineer. (See advertisement on another page.)

A Wireman is required for a large hospital. (See advertisement on another page.)

LOCAL NOTES

Belfast: *The Fire at the Power Station.*—The insurance claim for damages in respect of the recent fire at the electricity works (ELECTRICAL ENGINEERING, Sept. 2nd, p. 368) has been settled for £3,809. In reporting this, the Electricity Committee referred to the dismissal of the Resident Superintendent (Mr. Farrell), who, however, is said to have instituted legal proceedings against the Corporation.

Public Lighting.—In order to relieve the demands upon the electricity undertaking arrangements are being made for a reversion to gas for street lighting. In adopting this step the Electricity Committee remarks that this does not mean that the lamps will be sent to the scrap heap, but that when normal times are restored the City will return to electricity for street lighting.

Restriction of Electric Supply.—Consumers have been asked to reduce, as far as possible, their consumption of electricity between 4 p.m. and 5.30 p.m. At the same time the local electrical contractors have had the position of the Corporation in regard to capital expenditure explained. Owing to the refusal of the L.G.B. to grant loans, as already reported in our columns, the development of the undertaking as far as private consumers are concerned is being more or less held up, a position which, of course, affects the wiring contractors to a considerable extent.

Bristol: *Recruiting Results.*—Out of the total staff of 301 engaged in the Bristol Corporation Electricity Department, of whom 177 are married and 124 single, no less than 194 have volunteered, and 144 have been accepted. There are actually 77 members of the staff serving, the remainder being either in Reserve B under Lord Derby's scheme or in the Naval Reserve. Fifty men have been rejected, 70 are over age, 16 under age, and three are physically unfit. Thus it will be seen that the employees of the Bristol Electricity Department have not failed in their duty to their country.

Burnley: *Electricity Staff Enlistment.*—Out of the 26 employees of the Electricity Department eligible for military service, 25 have attested under Lord Derby's scheme, including the Borough Electrical Engineer, Mr. J. E. Starkie. They will not, of course, be called upon for immediate service.

London: L.C.C.: Tramway Supply.—In March this year the Council approved an estimate of £11,800 for cables in connection with a reserve supply of power for the tramways from an outside source. The contemplated agreement, however, fell through, and at present inquiries are being made with a view to obtaining a supply from elsewhere. Thus this cable is available for some other purpose, and it is proposed that part of it shall be utilised in the Woolwich district, where there is a constantly increasing demand for additional cars.

Marylebone: Enlistment.—The General Manager has been authorised to refuse any further permission for employees of the Department to enlist, on the ground that the staff is now at the very lowest level at which efficient working can be maintained.

Training Faraday House Students.—Arrangements have been made with Faraday House by which a number of fourth-year pupils will go to the electricity works for one year's practical training, the College paying the Council £25 per annum for each pupil.

Emergency Supply.—Consent has been given to arrangements with the Central Electric Supply Co. for taking an emergency supply should this be needed owing to damage to the Council's generating station by enemy aircraft. The connecting link between the Council's system and that of the Central Electric Supply Co. has now been completed and tested. In the event of this service being required by the Council, it would be necessary to pay the Company £12,000 by way of kw. charge. Insurance has been effected against this contingency at exceptionally favourable rates.

Manchester: Tax on Municipal Trading.—The Parliamentary Sub-Committee has had under consideration that portion of the Finance Bill dealing with excess profits duty. A resolution has been adopted to the effect that municipal undertakings should be excluded from the operation of this portion of the Bill, or in the alternative that all municipal undertakings in a town should be consolidated and treated as one, the excess profit duty being charged on the total profits after allowing for losses on any of the undertakings.

Street Lighting.—The responsible authorities have given permission for an increase in the present restricted lighting of the streets. It is the fact that only a short time ago the lighting in Manchester was considerably less than in London, but a certain improvement has been allowed. Now it appears

that still more lighting is to be permitted, at any rate, for at least two hours after sunset.

Nuneaton: *Curtis Geared Turbine.*—About a year ago the B.T.-H. Co. supplied the Corporation with a 750 kw. geared Curtis turbo-generator. This set has operated so satisfactorily that an order has been placed for a duplicate.

Sheffield: *Kelham Island Power Station.*—Steps are to be taken to transfer the Kelham Island power station from the tramways undertaking to the electric supply undertaking. A short time ago it will be remembered that the whole of the supply to the tramways was placed in charge of the electric supply department, Mr. H. E. Yesbury, the Tramways Electrical Engineer, going over to the Electricity Department as Assistant Engineer. Thus the proposed transfer is a purely formal matter.

Arrangements for the Week.—(To-day) Thurs., Dec. 9th. Institution of Electrical Engineers. Students' Section. Victoria Embankment. "The Institution," by J. E. Kingsbury. 7.45 p.m.

Fri., Dec. 10th. Greenock Electrical Society, 19 West Stewart Street. "Electric Tramways," by J. Punch. 7.45 p.m.

Sat., Dec. 11th. Birmingham Electric Club. Swan Hotel, New Street. Annual General Meeting. 7 p.m.

Mon., Dec. 13th. Institution of Electrical Engineers. Western Section. "The Design of High Pressure Distribution Systems," by J. R. Beard. S. Wales Institute of Engineers. Park Place. 5.30 p.m.

Tues., Dec. 14th. Institution of Electrical Engineers. Manchester Section, Engineers' Club. Albert Square. "The Design of High-pressure Distributing Systems," by J. R. Beard. 7.30 p.m.

Institution of Electrical Engineers, Scottish Section. Princes Street Station Hotel, Edinburgh. "Electric Heating: its Present Position and Future Development," by G. Wilkinson. 8 p.m.

Institution of Electrical Engineers, Birmingham Section. The University. "Notes on the Ignition of Explosive Gas Mixtures by Electric Sparks," by J. D. Morgan. 7 p.m.

Institution of Civil Engineers. "James Forrest" lecture. "Electrical Railways," by H. M. Hobart. Mr. J. A. F. Aspinall will read the lecture. 5.30 p.m.

Illuminating Engineering Society at Society of Arts, John Street, Adelphi. Discussion on "Recent Developments in Electric Incandescent Lamps in relation to Illuminating Engineering." 8 p.m.

Association of Supervising Electricians. St. Bride's Institute, Bride Lane, E.C. "Electric Lifts," by H. Marryat. 7.15 p.m.

Wed., Dec. 15th. Institution of Electrical Engineers. Students' Section. Victoria Embankment, E.C. "The Aluminium Electrolytic Arrester, with an introduction on Electrical Disturbances," by A. G. Ramsey. 7.45 p.m.

Thurs., Dec. 16th. Institution of Electrical Engineers. "The Design of High-pressure Distribution Systems," by J. R. Beard. 8 p.m.

Fri., Dec. 17th. Electro-Harmonic Society. Holborn Restaurant. Smoking Concert.

Institution of Mechanical Engineers, at Institution of Civil Engineers. "Engineering Colleges and the War," by Dr. R. Mullineux Walmsley and C. E. Larard. 6 p.m.

Music-hall Electricity.—"Dr." Walford Bodie was the defendant in an action in the Birmingham County Court last week in which a tailor's presser, suing for damages, alleged that he had been injured during a music-hall performance which "Dr." Bodie was carrying out. The plaintiff apparently went on to the stage in reply to an invitation by the defendant, and was asked to hold a handle attached to a battery as part of the "turn." It is alleged, however, that the plaintiff got a very severe shock, and had to go to hospital. As "Dr." Bodie is at present in South Africa, the hearing of the case was fixed for a date in April. We have some recollection that a few years ago this music-hall performer styled himself a hypnotist, mesmerist, bloodless surgeon, and medical electrician, and that in connection with a successful action for the return of £1,000 premium paid by a pupil, some very pointed remarks as to the genuineness of the show were made by Mr. Justice Darling. Some even stronger comments were made subsequently in the Appeal Court.

Tungsten Lamp Selling Prices.—The December issue of *The Electrical Contractor* states that a conference is now going on between the Electrical Contractors' Association and the Tungsten Lamp Association with regard to certain details which are regarded as in need of adjustment in connection with the sale of tungsten lamps.

The Electrical Industry and the Ministry of Munitions.—In the House of Commons on Monday Dr. Addison, speaking on behalf of the Ministry of Munitions, gave a list of business men, scientific experts, and employers of labour who are giving their services gratuitously to the Ministry. These include Sir Alexander Kennedy, Prof. Sir J. J. Thomson, F.R.S., Prof. Bernard Hopkinson, Sir George Marks, M.P., Mr. A. H. Pooley, Dr. S. Z. de Ferranti, Mr. W. H. Maw, Sir Hiram Maxim, Mr. S. S. Moore Ede, Sir Henry Norman, and Mr. A. J. Walter, K.C.

SUMMARY

THE United States Navy has ordered two battleships of the largest and most powerful class, which are to be electrically propelled (p. 498).

WE give an illustrated description of a 750 kw. D.C. geared turbo-generator, the successful trial of which at Nuneaton has resulted in a repeat order being given (p. 499).

RECRUITS are wanted for the Wireless Section (R.E.) and also for the Artists Rifles (O.T.C.) (p. 500).

NOTES on the working of the Liverpool Overhead and Mersey Railways formed the subject of Papers read at the Liverpool Engineering Society (p. 500).

OUR Questions and Answers page this week deals with the choice of a suitable frequency for proposed extensions to an existing mine installation (p. 501).

AMONG the subjects of specifications published at the Patent Office last Thursday were a new "arc incandescent" lamp with tungsten electrodes in an inert gas, condensers, and induction motors (p. 502).

MR. H. F. PARSHALL pays a tribute to the broad-mindedness which always characterised the late Mr. Thomas Parker (p. 502).

A SHORT article describes an interesting office electric-heating installation (p. 503).

THE Aberdeen extension scheme is to be deferred. Extensions are to be carried out at Redditch (£12,542) and Nuneaton (£10,000); mains are required at Burton-on-Trent (£3,500) and Hackney £3,000; and two electrically driven centrifugal pumps at Sydney (p. 503).

IT is stated that the British Carbide Co. is transferring its works from Norway to Manchester.—Whilst the whole of the fitters at the Luton Electricity Works were away attesting, a mechanical stoker broke down and caused an interruption in the supply (p. 504).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDING.

Drills, 6.25 to 7.25; 7.25 to 8.25 p.m.

(To-day) Thurs., Dec. 16th: Sections III. and IV., shooting.

Fri., Dec. 17th: Sections III. and IV., technical. Sections I.

and II., squad. Signalling sections and recruits.

Sat., Dec. 18th: Uniform parade. Time and place to be posted at headquarters.

Sun., Dec. 19th: Trench digging for Sections I. and II.

Mon., Dec. 20th: Sections I. and II., technical. Sections III.

and IV., squad. Signalling section and recruits.

Tues., Dec. 21st: School of Arms with Architects, 6-7 p.m.

Thurs., Dec. 23rd, to Thurs., Dec. 30th, inclusive.—Headquarters closed.

Fri., Dec. 31st.—Social evening, 6.15 to 8.15.

Sat., Jan. 1st: Uniform parade.

Officer of the Week: Monday, December 20th, to Saturday, January 1st, Mr. Corbett.

Platoon on Duty: Monday, December 20th, to Saturday, January 1st. No. 2 Platoon.

Platoon on duty has to provide a picquet for H.Q. of one N.C.O. and three men, and also one N.C.O. for instructing recruits.

Sections for technical parade at Headquarters, London Electrical Engineers, 46 Regency Street, S.W.

Sections for shooting parade at miniature ranges.

Unless otherwise ordered, all parades at Chester House.

The Osram v. Pope Patent Action.—Judgment was given yesterday in the appeal by the Osram-Robertson Lamp Works, Ltd., against the judgment of Mr. Justice Joyce that the metal filament lamp process worked by Pope's Electric Lamp Co., Ltd., does not infringe the Osram lamp patents. Lords Justice Warrington and Bankes held that the appeal must be dismissed with costs. The Master of the Rolls was not present. We will deal more fully with the judgment next week.

(For "Arrangements for the Week" see p. 503.)

SUBSCRIPTION RATES.

The postage on ELECTRICAL ENGINEERING is unaffected by the new postal regulations, and the subscription for the United Kingdom is as hitherto, 6s. 6d. per annum, post free.

REDUCED SUBSCRIPTION RATES FOR COLONIES AND ABROAD.

The subscription in future will be 8s. 8d. per annum, post free, instead of 13s. All subscriptions are payable in advance.

Orders should be addressed to and cheques made payable to—

THE KILOWATT PUBLISHING CO., LTD.,
Temple Chambers, London, E.C.

ELECTRICALLY-PROPELLED BATTLESHIPS To be Used in the U.S. Navy

AN extremely interesting announcement to electrical engineers was made in last Saturday's *Times*, namely, that the two battleships ordered to be built in the U.S. Government yards in accordance with the American programme of 1915 are to be electrically propelled. They will be equipped on the same lines as the *California*, which was laid down on October 14th last, and will be the first vessels in the world of the battleship class in which electric propulsion is employed.

A description of the equipment of the *California*, which is also being built in the U.S. Government yards, was given in a Paper read before the American Society of Naval Architects and Marine Engineers by Mr. W. L. R. Emmett last month, and reported in this country in the *Shipbuilding and Shipping Record* of November 25th. The contract for the electrical-propelling machinery for this battleship, which is of the largest and most powerful class adopted by the U.S. Navy, was awarded to the General Electric Co. Her displacement is 32,000 tons, and her maximum speed is to be about 22 knots, requiring about 37,000 s.h.p. The contract with the General Electric Company covers two turbine-driven generating units, four propelling motors (one for each shaft), switching apparatus, cables, instruments, &c., two turbine-driven exciting units, and a complete equipment of condensing auxiliaries and ventilating blowers, all driven by motors from the exciting units. In fact, it covers practically the entire engine-room equipment except the main condensers.

Each of the auxiliary units is of 800 kw. capacity with a 240-volt D.C. generator geared to a high-speed, non-condensing turbine. These turbines will exhaust into the heaters, into the main turbines, or both. The motors which drive the auxiliaries will be designed for a considerable range of speed variation, so that the auxiliaries will be adaptable to economical conditions at different speeds of the ship.

The award of this contract was the result of a very long "campaign of education," which had been conducted by Mr. Emmett, in which the equipment of the collier *Jupiter* was an incident. The *Jupiter* has now been in commission for two years, and has proved an unqualified success. The steam consumption of the main drive with 190 lb. pressure, dry steam, and 28.5 in. vacuum is 11 lb. per h.p.-hour delivered to the propeller shafts, which is at least 30 per cent. better than is done by reciprocating engines in ships of this class. There is also evidence of further saving in the *Jupiter*, incident to the fact that her large low-speed propellers are turned with a perfectly uniform angular motion and with entire freedom from racing, conditions heretofore unknown with such propellers.

The generators for the *California* are bipolar alternators, and the motors are arranged to be connected either for 24 poles or 36 poles. For economic cruising at 15 knots or less, one generator will be used with motors on 36-pole connection. For higher speeds the 24-pole connection will be used. The ship will be capable of operating at a speed of about 18.5 knots with one generator.

Speed variation with either motor connection will be effected by change of turbine speeds through the agency of variable speed governors designed to hold automatically any desired speed within usual ranges. This arrangement, which is also used in the *Jupiter*, entirely prevents racing, and makes it convenient to hold a fixed speed, irrespective of variations in sea, weather, or steam conditions. It is thought that this feature will be valuable in fleet formations.

The steam consumption guaranteed on the *California* covers the total steam required for the main turbines and engine-room auxiliaries as described above. The conditions are 250 lb. gauge pressure, dry steam, with such vacuum as can be produced under trial conditions. The guaranteed water rates per horse-power delivered to the propeller shafts are as follow:—

| | Lb. |
|-------------------------------|------|
| At 10 knots | 14.6 |
| At 15 knots | 11.4 |
| At 19 knots | 11.1 |
| Maximum speed | 11.9 |

Very heavy penalties are imposed in case these guaranteed consumptions are exceeded in trials, \$25,000 per lb. for the two lower speeds and \$20,000 per lb. for the two upper speeds.

At full speed the *California* propellers will make 175 r.p.m., this being about the lowest speed of propellers which is practicable within the space. The propeller speeds proposed

for the sister ships with Parsons turbine drive is 240 r.p.m., and comparisons by Dyson's method indicate that this speed difference will give the *California* an advantage of about 9 per cent. in propeller efficiency.

The following table gives a comparison of steam consumption per effective horse-power between the *California* as guaranteed, the *Florida* and *Utah* which are driven by Parsons turbines, and the *Delaware*, which is driven by reciprocating engines. These figures are taken from the published records of trials.

POUNDS OF STEAM TO MAIN ENGINES PER HOUR PER EFFECTIVE HORSE-POWER.

| | 12 kts. | 15 kts. | 10 kts. | 21 kts. | Prop. speed. 21 kts. |
|-----------------------|---------|---------|---------|---------|-------------------------|
| <i>Florida</i> ... | 31.8 | — | 24.0 | 23.0 | 328 |
| <i>Utah</i> ... | 28.7 | — | 20.3 | 21.0 | 323 |
| <i>Delaware</i> ... | 22.0 | — | 18.7 | 21.0 | 122 |
| <i>California</i> ... | 17.3 | 15.2 | 15.0 | 16.4 | 175 |

The estimated weight of the propelling machinery without condensing auxiliaries is 530 tons, and that of the turbines originally proposed was 653 tons.

Comparing the arrangement of the machinery of the *California* with the *Utah*, and a geared turbine equipment for a large warship shown in a paper by Sir Charles Parsons read in March of 1913, Mr. Emmett drew attention to the simplicity of piping, steam and vacuum connections with the electric drive as compared with the other methods. The *California* has two turbines, the *Utah* has 10, and the proposed Parsons geared equipment has 32. All of the steam passages between turbines in these arrangements, the author added, involve loss of useful pressure, and many of them involve risk of vacuum loss through air leakage, for it must be remembered that ships are often subject to vibration, and that there may be appreciable relative motion of these different parts through expansion strains or working of the ship, or through their own inertia when the ship is vibrating or labouring in a seaway.

It will be remembered that the collier *Jupiter* was put through a most severe test. She made a cruise from San Francisco to Philadelphia through the Panama Canal, and completed the trip in 23 days. During the war with Spain the *Oregon* made this trip from San Francisco to Philadelphia, via the Straits of Magellan, in 66 days, reaching Cuban waters in time to take part in the battle of Santiago. At the laying of the *California*'s keel Mr. Daniels said that the combination of electric drive and oil fuel would enable this vessel at 10 knots speed to steam for nine days longer than a coal-burning Dreadnought, and during that time she could cruise more than 2,150 miles farther.

NEW PUBLICATIONS

We shall be pleased to post any of the undermentioned works to any address in the United Kingdom, Colonies, or Abroad at the prices given. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

"Test Methods for Steam Power Plants." By E. H. Tenney. 224 pp. 8*1*/₂ in. by 5 in. 85 figures. (London: Constable and Co., Ltd.) 10s. 6d. net; abroad 11s.

"British Standardisation Rules for Electrical Machinery (excluding Motors for Traction Purposes)." Engineering Standards Committee. Report No. 72. 50 pp. 13*1*/₂ by 8 in. (London: Crosby Lockwood and Son.) 10s. 6d. net; abroad 11s.

A Theatre for War Workers.—Quite the latest in the provision of recreation and relaxation for war workers is the modern and most attractive picture and variety theatre which Messrs. Vickers, Ltd., have erected in the neighbourhood of one of their very large works. From the illustrations of the interior which have been sent us, Vickers' employees are distinctly to be envied.

A GEARED D.C. TURBO-GENERATOR

CERTAIN mechanical and electrical difficulties are inseparable from the design of continuous-current machines of any considerable output running at speeds approaching that desirable for an efficient steam turbine, with the consequence that up to the present time D.C. turbo-generators have developed very slowly, and it has in some cases been found worth while to use a combination of a turbo-alternator with

siderably increases the cost and the time required to build a machine.

With recent developments in the science of gear-cutting, however, effective gearing can be produced, to reduce the high turbine speed down to that of a moderate-speed generator, and an efficiency as high as 98 per cent. has been claimed, which reduces the full-load efficiency of 93.5 per

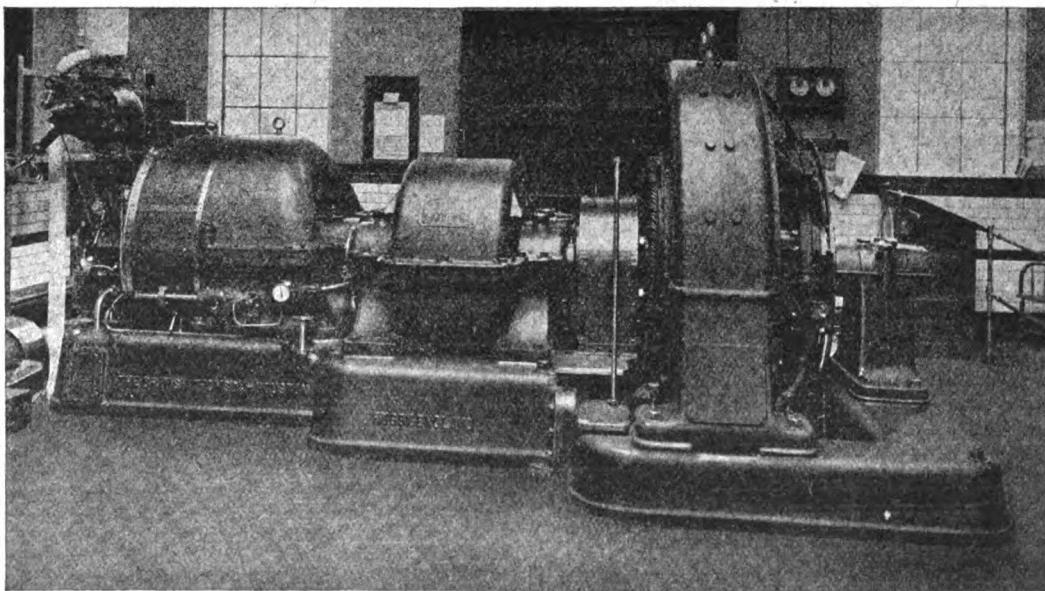

750-KW. B.T.-H. GEARED D.C. TURBINE SET.

a rotary converter, even when nothing but continuous current supply has been required. In fact, the direct-current generator is essentially a moderate-speed machine, and does not lend itself readily to construction for the high speeds of steam turbines. In building continuous-current direct-coupled turbo-generator sets, mechanical difficulties arise in the construction of the commutator, in securing the armature windings, and in arranging that the running speed shall not be near the

critical speed of a moderate-speed machine only down to 91.6 per cent. Even if the efficiency of the gearing is not quite so high as this under normal working conditions, it is obvious that the combined efficiency should be far greater than that of a turbo-alternator combined with a rotary converter.

We mentioned in our last issue (p. 496) the successful trial of a 750 kw. B.T.-H. geared D.C. turbo-generator at Nuneaton, which has resulted in an order for a duplicate set

PHOTOGRAPH OF THE SET AT NUNEATON.

critical speed. Electrical difficulties arise on account of the high reactance volts of the coils undergoing commutation and high volts per commutator segment. To ensure satisfactory operation a field structure with compensating windings is usually employed, and the consequent extra excitation losses, together with the rapid increase of core loss, friction, and windage at high speeds combine to reduce the efficiency considerably, in spite of reduced armature copper and shunt-field losses. The compensated field construction also con-

tinues to give. The practice followed by this Company as regards the dynamo itself may be outlined as follows:—

Thin laminations of special steel are used for armature core and pole-faces, to reduce the core loss, as the frequency of the armature currents before commutation will be 40 to 50 cycles per sec. Armature clamping bolts which pass through the core are insulated to reduce eddy currents. The air gap is made longer than would be the case with a slow-speed machine, so that the distortion of the main flux caused by armature reaction

is reduced. The commutating poles are so designed that over the whole working range, from no load to the guaranteed overload, the commutating flux is practically proportional to the load on the machine. The commutating-pole air-gap is adjusted on test so that the reactance volts of the coils undergoing commutation are exactly neutralised. Diverters across the commutating-pole windings are not used, as, although they form a convenient method of test adjustment, the amount of current diverted is apt to vary on account of changes of resistance due to temperature and variation of the resistance of connections, which, in the case of low-resistance windings, may form an appreciable item. Also, on varying loads, a plain diverter will not take a uniform share of the current, as its inductance is very much less than that of the winding. Inductive diverters are, in the B.T.-H. Company's opinion, difficult to adjust and are not satisfactory. Even when adjusted to operate perfectly up to heavy overloads, commutating machines are always liable to flash over on heavy short-circuits. To minimise the risk of flashing over and to reduce the damage caused by a flash, the clearance between adjacent brush brackets should be kept a maximum, and the space between the commutator and the bearing should be kept free from bus rings or earthed metal parts, as the flash always tends to spread outwards from the machine. Reference to the illustrations will show that the B.T.-H. design of brush gear fulfils these requirements. A substantial brush yoke supported from the magnet frame, brush springs designed to prevent brush chatter, and a carefully balanced armature, eliminate the mechanical causes of unsatisfactory commutation. Graphite brushes reduce the commutator loss to a minimum, and rapidly produce a hard polished skin on the commutator, the wear of which is very slight.

Equaliser rings fixed in an accessible position at the back of the armature prevent unbalanced magnetic pulls and equalise the distribution of the load between the several paths through the armature, which is, of course, parallel wound. The choice of a suitable speed and number of poles limits the volts per bar to a reasonable figure. The armature windings are secured against centrifugal force with an ample factor of safety by means of fibre wedges in the slot portion and steel wire binding bands on the ends.

The set above referred to, which was recently installed by Mr. Cameron Gibson, the Borough Electrical Engineer, in the power station of the Nuneaton Corporation, is an interesting example of a gear-driven set. It consists of a B.T.-H. shunt-wound generator having a normal output of 1,500 amps. at from 470 to 500 volts, driven through double helical gearing by a B.T.-H. Curtis turbine of 750 kw. normal capacity. The set has an overload capacity of 25 per cent. for two hours and 50 per cent. for five minutes. The complete set has been constructed by the B.T.-H. Company, and the turbine is of their standard three-stage design as used for driving alternators, and runs at 3,250 r.p.m., the gearing reducing the speed to 600 r.p.m. for the generator. The turbine drives the pinion shaft through a double claw-coupling, which allows the pinions to take their correct axial position without any end-thrust being transmitted to the turbine shaft. The armature spider is bolted direct to a large-flanged coupling on the slow-speed shaft, the bearings of which consequently carry a portion of the armature weight.

The gears and bearings are completely enclosed, and have a copious supply of oil from the main oil-pressure system of the turbine, which also operates the servo-motor of the well-known B.T.-H. governor gear. A return pipe from the bottom of the gear-case leads the oil back to the main oil tank, whence the oil-pump on the turbine delivers it through an oil-cooler back to the supply pipes.

This set was put on commercial load in January of this year, after exhaustive tests in the shops of the B.T.-H. Co. had proved that guarantees were fully met, and the completely satisfactory manner in which the set has behaved since its installation has given all concerned perfect confidence in the future of this combination, and resulted in the repeat order to which we have already alluded.

RECRUITS FOR R.E. WIRELESS SECTION

THE Wireless Section (R.E.) has vacancies for a number of electricians and instrument repairers with good practical knowledge. The need for this class of man in the wireless units is very great, and at the present time many men with the requisite qualifications, whilst wishing to enlist, may not know in what way to put their knowledge as skilled tradesmen to the best use. Enlistment for this purpose is for the period of the war only, and men would be required to enlist as sappers, but prospects of promotion for satisfactory men are very good.

Applications, stating qualifications, should be sent to the O.C., Wireless Training Centre, Worcester, from whom information regarding terms of service can be obtained.

ELECTRIC TRACTION NOTES

Two interesting Papers have recently been contributed to the Liverpool Engineering Society, entitled, "Notes on the Overhead Railway," by Mr. E. J. Neachell, and "Notes on the Mersey Railway," by Mr. Joshua Shaw. In both Papers the authors confined themselves to giving some particulars of the history of the undertakings and the working conditions and results obtained up to date.

The "Overhead" was the first elevated railway in the world to be operated electrically; its total length is 6½ miles. The permanent way consists of flat-bottomed steel rails on longitudinal sleepers. The life of the rails has been 13 years on the straight and five years on the curves, but it is expected to improve this by using better material. At the power station, which has a total annual output of 4½ million units, direct current is generated at 500 volts. Some notes are given on the automatic system of signalling, on station lighting, on rolling stock, and some interesting traffic details. A curve is also included in the Paper showing the number of passengers carried on the railway from 1893 up to last year, and it is interesting to note from this curve the effect of tramway competition, and of a temporary increase in railway fares.

In the Paper on the Mersey Railway, the notes on the power-station plant are interesting. The original plant, when this old steam railway was "electrified," consisted of three vertical cross-compound engines with generators of 1,200 kw. capacity each, and the normal method of operation was for one of these sets with a storage battery to work the periods of light traffic, and for an additional set to be put on during the peak loads. It was found, however, that the set was running lightly loaded during a great part of the day, and a mixed pressure turbine set of 800 kw. capacity was installed to take the light load. This effected a saving in steam consumption of 26 per cent. The financial results of the electrification appear to have been very satisfactory. A comparison of 1902, the last year of steam working, with 1913, shows a net annual increase of revenue of £37,000, after allowing for the interest on the additional capital, which had to be provided for electrification purposes.

Magnetic Testing.—A very useful historical review of the various methods of testing magnetic materials is given by Messrs. A. Campbell and D. W. Dye, of the National Physical Laboratory, in a Paper communicated to the I.E.E. and published in the *Journal*. This summary of methods used in the past affords to the practical experimenter a variety from which he can choose what is most suitable for his samples and equipment of instruments. The essential feature of the methods given is that the value of H, the magnetising force, is not calculated from the indefinite length of the magnetic circuit and the ampere turns, but is directly measured by the aid of a special form of search coil placed as near as possible to the surface of the iron, through which passes the flux in the air, but not the iron.

Tax on Electricity in Russia.—It is reported that the following taxes on electricity supply in Russia have been proposed: 4 kopecs per kw.-hour for current used for private lighting, theatres, shops, warehouses, &c.; 2 kopecs per kw.-hour for current used for lighting factories, &c.; 1 kopec per kw.-hour for current used for lighting streets and stations on private railways; and ½ kopec per kw.-hour for current used for heating and power. A kopec is about a ¼d.

The Royal Institution.—Among the lecture arrangements after Christmas are a course of six illustrated lectures adapted to a juvenile audience on "Wireless Messages from the Stars," by Prof. H. H. Turner, and three lectures on "The Utilisation of Energy from Coal," by Prof. W. A. Bone. The Friday evening meetings will commence on January 21st, and discourses will be given during the session by, among others, Prof. Silvanus P. Thompson, F.R.S., and Prof. Sir J. J. Thomson, F.R.S.

Artists Rifles O.T.C.—The Officer Commanding the 2nd Battalion of the Artists Rifles (Officers' Training Corps) has decided to form a special company to consist mainly of professional men whose technical experience renders them qualified for appointments as officers to those units or branches of the Army in which knowledge of construction and engineering is especially useful in the conditions obtaining in modern warfare. Applications for nomination to the Corps should be made to the Headquarters, 7 Duke's Road, Euston Road, W.C.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,473.

In a 3-wire A.C. 1-phase network (200 volts across outers) and the neutral not earthed, at normal times the pressure obtained from each of the outers to earth is 100 volts; the neutral, although unearthed, is at earth potential. When one of the outers develops a high resistance earth, the pressure from the unearthed pole to earth becomes 180 volts, from the earthed pole to earth 40 volts, and from the neutral to earth 50 volts. At the same time the normal pressure is obtained across the conductors. Why is this?

"SULPHUR."

(Replies must be received not later than first post,
Thursday, Dec. 23rd.)

ANSWERS TO No. 1,471.

I have about twelve motors, varying in size from 30 to 200 h.p., running on a 25-cycle, 3,000-volt system, all driving haulage gears. I propose to double this number of motors, at least, and to add motors up to about 500 h.p. for driving heavy haulages, air compressors, &c. Would it be efficient and worth the extra capital outlay for more flexible running and standardisation, &c., to change my system, to, say, 40 or 50 frequency? In order to do this I have to add considerably to my power-station units. In this case I should have to scrap the above 25-cycle system or instal some method for running 25-cycle motors from a new system of 40 or 60 cycles, assuming that my existing 25-cycle generators require absolutely renewing. What is the best arrangement for running 25-cycle motors from a 40-cycle system? And what are the principal factors to take into consideration for embarking upon such a scheme?

"REPRESENTATIVE."

The first award (10s.) is given to "W. H." for the following reply:—

The question put forward is one which can only rightly be answered by a consulting engineer after a prolonged investigation of the conditions. For instance, it would be necessary to take into account the capital expenditure required, as this would be a considerable amount; also as to whether the greater adaptability of the 40- or 50-cycle system would justify the greatly increased expenditure.

If it were decided to retain the 25-cycle supply the changes to the plant would only consist of the addition of new motors and corresponding generating plant. The points in favour of this scheme are the low initial cost and simplicity attained by having only one supply system installed.

The point raised by your correspondent regarding flexibility, although applying where high-speed motors are concerned, has little effect in a plant of this description. The reason for this statement is that motors for haulages and compressor drives are almost invariably slow-speed machines, thus having a fairly large number of poles even on 25-cycle circuits. It will be obvious, therefore, that speeds can be selected for the motors to suit most drives.

Again, the initial cost of the 25-cycle motors will be practically the same as that of 50-cycle motors in the case of these slow-speed machines. Also the 3,000-volt, 25-cycle generat-

ing plant would cost very little more than 50-cycle, 3,000-volt generating plant of the same capacity.

Regarding standardisation, I would suggest that no manufacturer in this country stocks motors, or wound portions thereof, suitable for 3,000 volts, 50 cycles, and therefore replacements and repairs would take an equal time for either 25-cycle or 50-cycle. It is assumed that transformers will not be used except possibly for the smallest sizes of motors.

The arguments given will show that for average circumstances it would be advisable to retain the 25-cycle supply system. If, however, special circumstances allow of scrapping the plant, I should strongly advise a 50-cycle system and a complete change over, so as to avoid having a dual supply.

If this is too drastic a procedure, it will be necessary to instal a frequency changer. This would preferably consist of a synchronous 50-cycle motor coupled to a 25-cycle generator. The speed would be approximately 500 r.p.m., thus making 12 poles on the motor and 6 poles on the generator, and at the same time allowing a reasonable speed for an exciter of sufficient capacity for both motor and alternator fields.

If the motor speeds are not very important, an induction motor could be used in place of the synchronous motor, but the supply from the generator would then be about 24½ cycles at full load. The cost of such a set of, say, 500 kw. capacity with switchgear would be in the neighbourhood of £1,800, and the synchronous set would be a little more expensive and slightly less efficient, but would have a better power factor on the motor side.

The second award (5s.) is given to "E. H." for the following reply:—

It is difficult to know why "Representative" wishes to alter the frequency of his system from 25 to 40 or 50. The main drawback of 25 cycles is the flickering of the light given off by arc lamps when working at that frequency. With filament lamps, however, this flickering is almost imperceptible.

In the case in question, it appears that the bulk of the power is absorbed by motors; consequently, it is the effect of frequency upon the working of the motors that demands most attention. Now, the higher the frequency, the greater are the number of poles required to give a certain speed; thus, a 1,450 r.p.m. induction motor must be wound for 4 poles when running off 50 cycles, but 2 poles give the same speed at 25 cycles. But increasing the number of poles on a motor decreases both its power-factor and its overload capacity, other factors being kept constant. Again, the efficiency of a 50-cycle system is, if anything, lower than that operating at 25 cycles, due to the greater iron losses in the machine, and to the slightly larger current required for a given power.

If "Representative" decides to instal 40 or 60-cycle plant, the present alternators might be used as the generators of the synchronous motor-alternator sets for supplying the 25-cycle motors, this being the simplest method of converting the frequency.

The principal factors to be taken into consideration in the above question are:—(1) The relative importance of the arc-lamp lighting and the power load. This is a matter of judgment, and cannot be expressed in £ s. d. (2) The relative costs of the new plant. The cost of replacing the present generators, and of the motor-alternators must be included in the estimate for the higher frequency. (3) The efficiency of the systems, the effect of the power-factor being taken into account.

It appears to the writer that in the case under consideration the best thing is to continue and extend the system with the 25 cycles. There are a number of supply companies working quite satisfactorily at this frequency.

The Commercial Motor Vehicle Parade.—The Tenth Annual Inspection of Commercial Motor Vehicles organised by the Commercial Motor Users' Association, will take place in May, 1916. Entries should be sent to the Secretary, 83 Pall Mall, S.W., not later than January 15th. There will be oral and written examinations for drivers of electric vehicles, and the Electric Vehicle Committee of the I.M.E.A. is presenting a number of prizes.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 9th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

22,437/14. "Arc Incandescent" Lamp. E. A. GIMMINGHAM. A lamp of the same size and shape as an ordinary incandescent lamp, in which an arc is produced between tungsten electrodes in an inert gas. A heater is provided for ionising the gas. One electrode is in parallel with one end of the heater, and the other electrode is formed by the ioniser or by a shield thereon. The current is automatically cut off from the heater a short time after starting. A small quantity of barium chloride is provided in the bulb, which at the working temperature gives off a minute quantity of oxygen for facilitating the initiation of the arc. (Seven figures.)

22,931/14. Condensers. GALVANOPHOREN-WERKE (SYSTEM VOGT), S. SZUBERT, KOMMANDITGESELLSCHAFT & VEREINIGTE ELEKTRICITÄTSWERKE GES. A method of manufacturing air condensers in which the sets of plates are cast under pressure in one piece, together with the intermediate portions for the distance of the plates. (Three figures.)

23,676/14. Heating Elements. F. S. GROGAN. An improved heating element for hot plates, grills, &c., consisting of a grid of resistance coils constructed of flat metal tape coiled into a helix of small diameter, with the convolutions separated from one another, and without further insulation between them or other support. The convolutions near the centre of the frame are further apart than at the edges to equalise the temperature. (Six figures.)

3,502/15. Induction Motors. B.T.-H. Co. (G.E. Co., U.S.A.). Rotor for induction motors in which the conductors, end rings, and spider are formed of a single piece of aluminium cast on to the laminations. (Two figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: OATES [Cable conduits] 2,883/15; UREN and GAMBLE [Conduit joints] 8,458/15.

DYNAMOS, MOTORS, AND TRANSFORMERS: A.E.G. [Cooling of turbo-generators] 22,950/14.

Electrometallurgy and Electrochemistry: BASSANESE [Tilting electric furnace] 1,173/14.

Heating and Cooking: MAJESTIC ELECTRIC DEVELOPMENT CO. [Radiator] 1,740/15; JACKSON ELECTRIC STOVE CO., GRIESBACH, HOLMES, SMITH, and WILLIAMS [Cooking] 9,158/15.

Ignition: STRETT [Sparkling plug taster] 24,589/14; SIMPSON [Contact breakers for magnetos] 5,673/15.

Incandescent Lamps: TERRY [Incandescent lamps] 23,113/14; W. SANDERS & CO. and SANDERS [Incandescent lamps] 1,715/15.

Instruments and Meters: LANDIS AND GYR, S.A. [Prepayment meters] 20,146/14.

Switchgear, Fuses, and Fittings: SIEMENS & HALSKE A.G. [Remote control apparatus] 22,297/15; ELECTRIC & ORDNANCE ACCESSORIES CO. and ETCHELLS [Switches] 23,321/14; B.T.-H. CO. (G.E. CO., U.S.A.) [Switches and circuit-breakers] 2,386/15; GILES [Switches] 5,943/15.

Traction: SAMUEL, SLINGO, GUNTON, and DOUGLAS [Railway system] 10,951/15; SAMUEL, SLINGO, GUNTON, POWELL, and KINGSTON [Railway system] 10,958/15.

Miscellaneous: B.T.-H. CO. and WHEAT [Illumination of surfaces] 23,072/14; B.T.-H. CO. (G.E. CO., U.S.A.) [Vapour electric devices] 23,122/14; H. W. COX & CO. and DONNITHORNE [X-ray apparatus] 23,236/14; R. BOSCH [Regulators] 1,609/15; BOBROFF and UNIVERSAL INDICATOR CO. [Signalling apparatus] 5,629/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

DYNAMOS, &c.: GIRARDEAU [DYNAMOS] 16,107/15.

Telephony: RELAY AUTOMATIC TELEPHONE CO., LTD. [Automatic telephone systems] 12,673/15.

The following are the more important Patents that have become void through non-payment of renewal fees.

Electrochemistry and Electrometallurgy: F. J. CLARKE [Electrolysis] 17,152/05.

Storage Batteries: A. J. BOULT (Allgemeine Akkumulatoren-fabrik) [Battery plates] 17,750/08.

Switchgear, Fuses and Fittings: VERITY'S, LTD., and A. E. GOTTR [Rheostats] 17,146/05; W. A. G. HILL [Shade holders] 17,706/08.

Traction: J. W. MACKENZIE (U.S. Motor Vehicle Co.) [Electric heavy chassis with four wheel drive] 18,975/06.

the same time naturally felt that the established system was the safer one to use.

I should like to say that at all times Mr. Parker looked at the different problems in the broadest possible way, and his whole attitude was characterised by absolute fairness, and was not aggressively partisan, a characteristic that has not been particularly marked in those advocating the high-tension overhead alternating-current traction systems.

My mind turns back on this arbitration with particular pleasure on account of the association with the Hon. Alfred Lyttelton, who, while he viewed the whole problem very largely from a legal point of view, decided broadly, on the basis of the three-phase system being experimental, that the Metropolitan Company had no right to adopt a system which would impose an experiment on the District Railway.

Both of these gentlemen have now passed from us, and although the system of which I was a special advocate for the purposes of the Underground Railway was approved, there remains the pleasantest memory as regards the fairness and the broad-minded way in which the whole of the numerous arguments advanced were dealt with.

I met Mr. Parker a great many years ago at his works at Wolverhampton, and the opinion I then formed of him was always retained, viz., that he was an engineer graced with the most broad and kindly instincts.

Yours truly,

H. F. PARSHALL.

Salisbury House,
London Wall, E.C., Dec. 10th.

AN ATTRACTIVE "WOTAN" SIGN

WE illustrate one of the new "Wotan" showcards which Messrs. Siemens Bros. Dynamo Works, Ltd. (39 Upper Thames Street, E.C.), are now issuing for trade display. This showcard is a collapsible box arrangement having a black

velvet background, against which the cut-out of the "Wotan" lamp is silhouetted. It is of handy size (11 in. by 7½ in.), and is reproduced in effective colours. It can be used for counter, desk, or window display, and will be supplied to customers on receipt of inquiry.

CATALOGUES, PAMPHLETS, &c., RECEIVED

MILITARY TELEPHONES.—A number of patterns of field and rifle-range telephones are included in a well-printed list sent us by James McMillan & Co. (Clun House, Surrey Street, W.C.).

CALENDAR.—An exceptionally well got up and printed almanac for 1916 has been sent us by Messrs. Abdulla & Co., the cigarette specialists, 168 New Bond-street, London, W. It contains reproductions of drawings and paintings by a large number of well-known artists, and three of the pictures were exhibited this year at the Royal Academy; 20,000 copies of this almanac have been given for sale for the benefit of the funds of the British Red Cross Society, and it is hoped that at least £1,000 will be realized.

Arrangements for the Week.—(To-day) Thurs., Dec. 16th. Institution of Electrical Engineers. "The Design of High-pressure Distribution Systems," by J. R. Beard. 8 p.m.

Fri., Dec. 17th. Electro-Harmonic Society. Holborn Restaurant. Smoking Concert.

Institution of Mechanical Engineers, at Institution of Civil Engineers. "Engineering Colleges and the War," by Dr. R. Mullineux Walmsley and C. E. Larard. 6 p.m.

Mon., Dec. 20th. Junior Institution of Engineers, at I.E.E., Victoria Embankment. "Modernisation of Power Plant in Factories," by W. A. Tookey. 7.30 p.m.

German Electrical Standards in Portugal.—H.M. Minister at Lisbon reports, says the *Board of Trade Journal*, that in almost all matters concerning electrical installations, fittings and material in Portugal, and in the rules and instructions governing such installations, the Portuguese Government have adopted the regulations of the "Verband Deutscher Elektrotechniker," and this has had the effect of putting the electrical engineering trade largely in German hands. The stoppage of electrical supplies from Germany, however, since the war commenced, is causing serious difficulties to the electrical trade in Portugal, and as a result of H.M. Minister drawing the attention of the Portuguese Government to the matter, it has been decided to include British standards within the Portuguese law. It is hoped that this concession will facilitate the export of British electrical material to Portugal.

Fire at Ediswan Works, Ponders End.—Owing to the fact that erroneous reports have been circulated that the fire at the Ponders End Works of the Ediswan Co. was very serious, we state the true facts:—On Saturday, the 11th inst., a fire broke out in the joiners' shop, which is an extensive building of two floors, employing nearly ninety hands. Fortunately the fire did not spread, and was confined entirely to that department. The "self-contained" nature of the Ediswan works, however, enabled things to be set going on Monday morning when work was resumed.

INDUSTRIAL ELECTRIC HEATING

THE use of electricity for heating dwellings, shops, show-rooms, &c., has made vast strides forward during the last year or two, and now that the necessity to practise economy in all establishments, including factories, workshops, and offices, is being felt, electricity is taking its proper place as the heating medium. Besides the growing use of electric heating in new factories, workshops, and offices, cases are on record where a change-over has been made, from steam to electric heating, as it has been found to be pleasanter and more hygienic. One of those go-ahead firms which has carefully gone into the question of steam, hot-air, electric and other forms of

"MAGNET" ELECTRIC FIRE INSTALLATION.

heating for offices is Messrs. Edward Cook & Co., Ltd. (East London Soap Works, Bow). This firm thoroughly tested steam heating throughout its new offices, and finally decided to replace it by an electric heating system on the "Magnet" panel type electric fires. Thirty 1·5-kw. and twenty 2-kw. "Magnet" fires have been installed throughout the various offices, telephone operating room, typewriting and post departments, &c. The illustration above shows some of the "Magnet" electric fires in the general office. "Magnet" fires, of course, are made by The General Electric Co., Ltd., at its Birmingham works.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Aberdeen.—The extension scheme estimated to cost £21,000, referred to in our last issue as having been adopted by the Electricity Committee, was discussed at some length at the Council meeting last week. Eventually it was defeated by 17 votes to 14, notwithstanding the statement of the City Electrical Engineer that he could not undertake to maintain the full supply with the present plant. The rejection of the scheme is understood to be for twelve months.

Burton-on-Trent.—Application is to be made for a loan of £3,500 for mains extensions. It is stated that some of the existing mains are already over-loaded, and that the extensions are necessary in order to deal with new consumers waiting to be connected.

London: Hackney.—An estimate of £3,000 has been approved in connection with the linking up with Poplar.

Monaghan (Ireland).—A meeting of the ratepayers is to be called to decide whether permission shall be given to a company to carry out an electric lighting scheme by means of overhead wires. One of the points of controversy appears to be that the new company proposes to buy out the existing gas company.

Nuneaton.—The L.G.B., writing with regard to an application for a loan of £10,000 for extensions to the power-house, states that having given the matter further consideration, no exception is taken to the Council entering into definite contracts for the plant.

Redditch.—A loan of £12,542 is in contemplation in connection with extensions at the power-house.

Miscellaneous

Australia.—The Sydney Corporation requires two electrically-driven centrifugal pumps, each capable of pumping 4,000 gallons per minute, together with the necessary starters, spare

parts, &c. Tenders to the Metropolitan Board of Water Supply, 341 Pitt Street, Sydney, by February 7th.

The above notice is only of use to firms who can cable agents.

Colombia.—In a list of goods in demand at Bogotá, hitherto supplied by German firms, H.M. Minister in that city writes that electric light fittings and shades should be included.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Gillingham.—The Council is to purchase three Edison electric vehicles, at a cost of £8,500. The contractors, Messrs. A. H. Johnson & Co., Ltd., are to be asked to accept six half-yearly payments, plus interest on the unpaid amount at 5 per cent. per annum.

Pembroke (Ireland).—Subject to the L.G.B. sanction, a Diesel engine is to be purchased from Messrs. Sulzer Bros. The Borough Electrical Engineer has intimated that he cannot carry on the work of the Department without a new engine.

Southampton.—The tender of the British Insulated & Helsby Cables, Ltd., for 450 yards of 1-inch high-tension concentric lead-covered paper-insulated cable and 800 yards of 0·25 sq. inch cable, have been accepted at £121 10s. and £90 18s. respectively.

LOCAL NOTES

Glasgow: Cookery Demonstration.—Mr. W. W. Lackie, the Corporation Electrical Engineer and Manager, has sent us a copy of a folder and invitation to Cookery Demonstrations in the Corporation's showrooms. These are being sent out to consumers, and a specimen menu is appended to the invitation.

Hove: Change from 110 to 220 Volts.—The Lighting Committee reports that there are two consumers who refuse to be changed over from 110 to 220 volts. In consequence of the extra expense of supplying these two consumers at the lower voltage, the Board of Trade is to be appealed to in the matter.

Hythe: Cost of Public Lighting.—The cost of public electric lighting under normal lighting conditions is £850 per annum, but an agreement has been come to with the Folkestone Electric Supply Co. for the charge to be reduced to £425 whilst all public lamps are extinguished. In the event of re-lighting being permitted, the charge will be increased *pro rata* according to the number of lamps.

Luton: Failure of Supply.—The failure of the supply of electricity in Luton for a short time on Thursday last week was due to a curious, but nevertheless interesting cause. It appears that at 9 o'clock in the morning the whole of the fitting staff, who are starved men, went to the recruiting office for the purpose of being attested under Lord Derby's scheme. Whilst they were away, one of the mechanical stokers went wrong, and put a boiler out of action. Although there was another boiler practically ready for use, a certain amount of work had to be done upon this, and there was nothing for it but to fetch the men, still unattested, back from the attesting station, with all speed. This was done, and the supply was quickly resumed.

Manchester: A New Power Customer.—During the course of an inspection of the Corporation's power stations last week by the members of the Electricity Committee, it was stated that the British Carbide Co. is transferring its works from Norway to the vicinity of Stuart Street, owing to the advantage of the cheap supply of electric power which is available there.

Newquay: Proposed Increase in Charges.—A short time ago we reported that opposition was being offered to the proposal of the Newquay Electric Supply Co. to increase the maximum charge under its Provisional Order from 6d. to 8d. A local inquiry was held last week on behalf of the Board of Trade, when it was stated that the Company was actually under the impression that 8d. was in the original Order until the agreement with the Council came to be negotiated. At the conclusion of the inquiry the inspector expressed the opinion that the Company had not made out an overwhelming case, but they had made out something of a case for consideration owing to war conditions. Eventually an agreement was

arrived at with the Council for the maximum price to be increased to 7d. until after the expiration of one year after the conclusion of peace.

Peterborough: Coal Prices.—The Town Clerk has been in correspondence with the coal contractors to the Electricity Department as to the amount of the abatement to which the Corporation is entitled under the Coal Supply (Limitation) Act, 1915. Negotiations are still proceeding, and the Acting Borough Electrical Engineer is communicating with other municipal electrical engineers on the point.

Wednesbury: Difficulties of Supply.—The Electricity Department have been experiencing a little difficulty in maintaining full supply to all consumers, but it is anticipated that the delivery of a new rotary converter will remedy matters to a large extent. The new machine was ordered in June last for delivery in October, but, as in many other places, there have been serious delays, for obvious reasons.

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £97 to £98 (last week, £97 10s. to £98 10s.).

Liquidation.—The Renew Electric Lamp Co., Ltd., is to be wound up voluntarily. Mr. J. E. Percival, 6 Old Jewry, E.C., is liquidator, at whose address a meeting of creditors will be held to-morrow (Friday).

New Address.—As will be seen from our advertisement columns, the Electrical Supplies Co., Ltd., has now moved into the Light House, 233 Tottenham Court Road, London, W.C. The telephone numbers are Museum 2516 and 2517, and the telegraphic address Elecsplico, Ox-London.

APPOINTMENTS AND PERSONAL NOTES

We owe Mr. H. E. Yerbury, Deputy General Manager and Engineer to the Sheffield Corporation Electric Supply Department, an apology for a slight inaccuracy on page 496 of our last issue. We referred to him as the "Assistant Engineer," and at the same time a slip in the spelling of his name escaped notice.

The B.E.A.M.A. has made a second donation of £200, making a total of £1,000, to the *Times* Fund for the Sick and Wounded, on behalf of the British Red Cross Society.

Mr. C. E. Garnett, Borough Electrical Engineer, Darwen, has enlisted under the group system.

Mr. C. W. Salt, Borough Electrical Engineer, Torquay, has been granted leave of absence to join the Forces. The Assistant Electrical Engineer will carry out the duties meanwhile. Already 24 members of the Department have joined, and there are only five eligible men left, regarding whom an appeal is to be made on the ground that they are indispensable.

Charge Engineers are wanted for tramway sub-stations. (See an advertisement on another page.)

Lanarkshire Tramways Co. want a Shift Engineer. (See an advertisement on another page.)

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

India Rubber, Gutta Percha & Telegraph Works Co., Ltd.—There was a net profit of £80,404 for the year ending Sept. 30th. The final dividend, making 10 per cent. for the year, is declared on the ordinary shares. The general position of the Company is extremely satisfactory.

British Electric Traction Co.—The capital re-organisation scheme referred to in our columns on several occasions was sanctioned by Mr. Justice Astbury in the Chancery Division last week. There was some opposition by a minority of the Income Certificate holders, who were, however, allowed their costs.

Newcastle-on-Tyne Electric Supply Co.—The interim dividend of 2½ per cent. on the ordinary shares postponed in July, is now to be paid.

SUMMARY

WE give the reasons why the Court of Appeal has upheld the judgment of Mr. Justice Joyce that the process of metal filament lamp manufacture used by Pope's Electric Lamp Co., Ltd., does not infringe the Just & Hanaman patent No. 23,899 of 1904 (p. 506).

IN the course of an interesting discussion at the Illuminating Engineering Society last week the new arc-incandescent lamp which is being developed by the Edison & Swan Co. was exhibited and demonstrated. Mr. F. W. Willcox, of the British Thomson-Houston Co., differed from Professor J. T. Morris as to the advantages of the horizontal spiralled filament lamp unless advantages can be shown in higher efficiency, as in the case of the half-watt lamp (p. 506).

THE electrification has now been completed of a section of the main line of the Pennsylvania Railroad at Philadelphia. The equipment is single phase with repulsion starting series motors (p. 507).

AN interesting and important action is pending in which the question of the validity of contracts for electric power supply entered into before the war is raised. The West Bromwich Corporation has threatened, owing to the extra cost of fuel since the war, to increase by 20 per cent. the charges agreed to with a power consumer in 1912 (p. 507).

AMONG the subjects of specifications published by the Patent Office last Thursday are renewable incandescent lamps, circuit-breakers, H.-T. switches, conduit joints, and self-contained cooking utensils without flexible leads. Applications for suspension of seven enemy patents relating to Thermit rail welding will be heard tomorrow. Patents having reference to magnetic blow-out controllers and varnished fabric insulation of cables expire this week after a full life of fourteen years (p. 508).

OUR Questions and Answers columns this week deal

with the cause of the momentary large rise of current which sometimes happens on switching a transformer into circuit (p. 508).

WE describe new electric heaters, &c., and also half-watt lamp fittings (p. 510).

WE illustrate the first form of the new tungsten arc lamp which is being developed by the Edison & Swan Co., Ltd. This is for projector lanterns (p. 511).

WE describe a rough test of a new dry cell which was practically unaffected by long periods of short-circuit (p. 511).

MAINS and services are required at Marylebone (£3,800), and Kingston-on-Thames (£3,307). A considerable expenditure is in prospect upon electric lighting and tramways in New Zealand (p. 512).

CONSIDERABLE additions are to be made to the electricity charges at Brighton.—Difficulties which are being experienced with coal supply at Manchester were mentioned in the House of Commons last week (p. 512).

THE London Electrical Engineers R.E. (T.F.) is again open for recruiting (p. 512).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDING.

Drills, 6.25 to 7.25; 7.25 to 8.25 p.m.

Thurs., Dec. 23rd, to Thurs., Dec. 30th, inclusive.—Headquarters closed.

Fri., Dec. 31st.—Social evening, 6.15 to 8.15.

Sat., Jan. 1st: Uniform parade.

Officer of the Week: Monday, December 20th, to Saturday, January 1st, Mr. Corbett.

Platoon on Duty: Monday, December 20th, to Saturday, January 1st. No. 2 Platoon.

Power Tariffs in Berlin.—Changes are being made in the conditions and rates for power supply by the Berlin Elektricitäts Werke. The fee formerly payable for connection will not be required, nor the fee for testing the installation before connecting. The most important alteration is a revision of the rates for industrial power supplied from the H.T. mains. In the past the usual contract was made on the basis of a ten years' agreement with a minimum annual consumption of 200,000 units, the charge being based on the consumer's average load factor during the year, expressed as the "Benutzungsdauer" (the equivalent number of hours consumption at maximum demand), obtained by dividing the total consumption in kw. hours by the maximum demand in kw. between 4 p.m. and 7 p.m. in the winter months. This calculation has always been a source of misunderstanding and dispute, and is to be avoided by the adoption of the system now so much favoured in this country and known as the "telephone system." A fixed charge of from 10 to 7 marks per month per kw. of maximum demand plus three pfennigs per unit will be charged (approximately £6 to £4 4s. per kw. per annum of maximum demand plus 0.36d. per unit), the amount of the fixed charge per kw. depending upon the extent of the consumer's demand. The maximum demand will be determined by a maximum-demand meter as before.

THE OSRAM v. POPE PATENT ACTION

Chancery Judgment Confirmed

A S briefly announced on p. 497 of our last issue, the Appeal Court has upheld the judgment of Mr. Justice Joyce in the Chancery Division that the process used in the manufacture of Pope metal filament lamps does not infringe the Osram patents. Mr. Justice Joyce's judgment was given on p. 311 of our issue for July 22nd, and the proceedings in the case were reported in our issues for July 1st, p. 283; July 8th, p. 294; and July 15th, p. 304. The Appeal Court consisted of the Master of the Rolls (Lord Justice Cozens-Hardy) and Lords Justices Warrington and Bankes. When the judgment was given on Wednesday last week, however, the Master of the Rolls was not present, but he intimated, through Lord Justice Bankes, that he concurred in the finding of his colleagues.

The patent which the Osram Lamp Works had alleged was infringed was that of Just & Hanaman, No. 23,899 of 1904, and the material parts for the purpose of the action are as follows:—

For the manufacture of filaments of this kind finely divided tungsten or tungsten compounds such as tungstite, tungstic acid, or tungstic sulphide are mixed with an organic binding medium, such as collodion or a solution of cellulose in chloride of zinc or cupreous ammonia oxide or the like, from which mass filaments are formed in the usual manner, and are then carbonised, in some instances after denitration has previously been effected. The filaments so produced and consisting of tungsten and carbon are then submitted to the following further treatment.

First of all the carbon, which has only served as a binding medium, is removed by subjecting the filaments to the passage of current in an atmosphere of steam and hydrogen, and thus raising it to a high temperature. By this process the carbon is completely oxidised so as to form carbonic oxide and a filament of tungsten is left. These filaments are then rendered uniform in a manner similar to that employed in the treatment of the usual carbon filaments, by submitting them to the action of current in an atmosphere of volatile tungsten compounds in the presence of a large quantity of hydrogen whereby the tungsten deposited equalises the filaments. The filaments which have been rendered uniform in this way are then sealed in glass bulbs in the usual manner, and these latter are exhausted.

Mr. Justice Joyce held that the Pope Co. do not use any of the processes of carbonisation set out in the patent, nor do they use an atmosphere of steam and hydrogen in the sense in which the phrase was used in the specification or was intended by the patentees. Indeed, he did not think the defendants used steam at all in the ordinary sense.

Lord Justice Banks, in his judgment, detailed the steps followed in the Pope Co.'s process as set out during the proceedings before Mr. Justice Joyce, and then pointed out the main points on which the two processes differ. In the first place, he said, the Just-Hanaman process involved the use of a soft material, whereas in the Pope process a hard material was used. In the second place, carbonisation under the patent was done separately and before any attempt was made to decarbonise, whereas in the Pope process carbonisation and practically the whole of the decarbonisation are done at one and the same time in the first furnace or in the vacuum, as the case may be. In the third place, the heat necessary for the decarbonising part of the process as described in the patent was produced by passing an electric current through the filaments, whereas the Pope Co. applied the heat externally. In the fourth place, under the patent the filaments were exposed to a previously prepared atmosphere of steam and hydrogen, which was not the case in the Pope process. In some respects the differences might be differences of degree rather than of kind, but, having considered the question whether the defendants' process as a whole, and having regard particularly to the four points indicated above, was substantially the same as the process set out in the patent, he was of the opinion that it was not. In his view, the differences passed the border line which separates a difference in degree from a difference in kind, and the process as a whole was, in his opinion, substantially different from the one described in the patent. Therefore the appeal failed, and would be dismissed with costs.

Lord Justice Warrington, who concurred, said that the process used by the Pope Co. started from a different standpoint to that of the patent. The several steps in it were different in nature and had different aims and results, and the variations in it, as compared with the patent, were not merely colourable alterations.

At the conclusion of the reading of the judgments Mr. A. J. Walter, K.C., for the Osram Co., said he presumed the Court would not grant a stay.

Lord Justice Bankes: No.

RECENT DEVELOPMENTS IN INCANDESCENT LAMPS

AT the Illuminating Engineers' Society on Tuesday last week a discussion took place upon recent developments in electric incandescent lamps in relation to illuminating engineering. Professor Silvanus P. Thompson, F.R.S., was in the Chair.

Dr. J. T. Morris opened the discussion, and after tracing the history of the electric incandescent lamp from the earliest Swan lamp, dealt at some length with the tendency to adopt horizontal spiral filaments instead of the vertical hair-pin type. One advantage of these, he said, is that the light can be controlled more easily, although his experience had been that the life is something like 20 per cent. shorter. This, however, he did not regard as serious, because the cost of current in a lighting installation was very much larger than the cost of lamps, and even with a life of only 200 or 300 hours the total running cost of an installation might be less than with the older type of filament on account of the greater efficiency of the spiral filament. Professor Morris described the new arc-incandescent lamp which is now being developed by the Ediswan Co.; this was described in our issue of Dec. 9th, and is further illustrated this week. In this connection tests of the relation of candle-power to voltage which Professor Morris has carried out are interesting. Whereas with the carbon filament lamp a 1 per cent. change in voltage usually means a 6 per cent. change in candle-power, with the new arc-incandescent lamp the change of candle-power with 1 per cent. variation in voltage is only $\frac{1}{4}$ per cent. Finally Professor Morris made a suggestion that with these new forms of spiralled filament lamps a polar curve should be given on the wrappings they are sold in, so that the purchaser would have a good idea of what the candle-power was supposed to be in particular directions.

Following Professor Morris's remarks, Mr. S. R. Mullard exhibited and demonstrated the new arc-incandescent lamp of the Edison & Swan Co., and pointed out that they have been made in the laboratories up to 1,200 candle-power, both electrodes being of tungsten.

Mr. F. W. Willcox (British Thomson-Houston Co.) discussed in some detail the change in design and character of fittings necessitated by the introduction of the half-watt lamp in particular, and spiralled filament lamps in general, but did not share Professor Morris's view that this type of filament would necessarily replace the vertical filament. This could only be, he said, if there was greater efficiency, as in the case of the half-watt lamp. Being a much shorter filament, the spiral was bound to be much hotter, and consequently the life shorter.

Several other speakers took part in the discussion, including Mr. W. R. Cooper, who asked for further details of the arc-incandescent lamp; Mr. A. E. Cunningham, of the London & South-Western Railway Co., who raised the question of the necessity for standardising the expression of the candle-power of these new forms of lamps, and also discussed the advantages of under-running half-watt lamps; Mr. E. Stroud, of the Holophane Company, who disagreed with Mr. Willcox that it is necessary to have special reflectors for half-watt and horizontal filament lamps, although he agreed that greater care is necessary in adjusting the position of the lamp in the reflector in order to get the illumination in any desired direction; and Mr. L. Gaster, who urged manufacturers not to push these new forms of lamps until they are absolutely satisfactory from every point of view.

In winding up the discussion, Professor Silvanus Thompson twitted manufacturers in connection with the high prices now charged for incandescent lamps, which, he said, he was quite certain was very much higher than they need be.

The Institution and Enemy Members.—The Journal of the Institution of Electrical Engineers for December 15th states that representations have been made to the Council by certain members to the effect that members of enemy origin and nationality should be excluded from membership. It is pointed out, however, that the Council is legally advised that the only powers of expulsion which the Institution or its Council appears to have are those contained in Article 41 of the Articles of Association. May we remind the Council, however, that there is nothing to prevent, if it is thought advisable, the Articles of Association being revised at a special general meeting of the members? A letter on this subject appeared on p. 492 of our issue for December 9th.

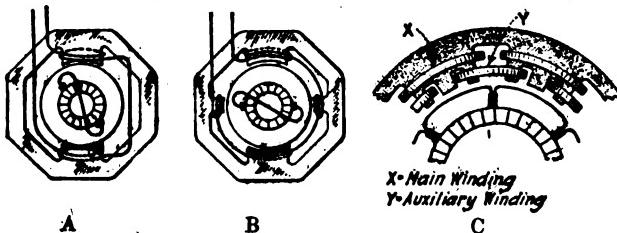

The B.E.A.M.A.—The following firms have recently been elected members of the B.E.A.M.A.: Cole, Marchant & Morley; Hick, Hargreaves & Co.; The Edison & Swan United Electric Light Co.

THE REPULSION-STARTING TRACTION MOTOR

THE adoption of single-phase power supply with repulsion-starting series motors, for the electrification of the suburban line of the Pennsylvania Railroad at Philadelphia, marks a new step in the progress of electric traction. The electrified section of this railway, which is described at length in the *Electric Railway Journal*, is about 20 miles long, and the rolling-stock consists of 93 all-steel cars, all equipped as motor cars.

Each car is provided with two 225-h.p. Westinghouse single-phase, air-blast-cooled motors, mounted on one truck. All the main electrical apparatus is placed at one end of the car, and the brake equipment at the other, giving about 60 per cent. of the total car weight on the driving wheels. The motors are connected in series, and are started and operated up to 15 miles per hour as repulsion motors, with the compensating field, the armature, and the main field in series. With these series connections the armature is short-circuited through resistance. Resistance is also inserted in series with the motors on the first step, and is cut out on the second step. The third step changes the connections to energise the compensating field from one portion of the transformer, and the armature and main field in series, from another portion, thus affording doubly-fed connections. The armature short-circuit is removed when the motors are operating with the double feed. Subsequent steps in the control serve to increase the motor voltages.

Each motor has a continuous rating of 200 h.p. when ventilated with 1,200 cu. ft. of air per minute. The armature is of standard construction; the commutator and the laminations are mounted on the spider, the former being undercut $\frac{1}{16}$ in. The armature is wave-wound and cross-connected, and no resistance leads are used between the windings and the commutator. The field windings consist of two entirely independent sets of coils, one being the main field circuit for producing the effective magnetic field, and the other the auxiliary or compensating winding which balances the arma-

PHILADELPHIA-PAOLI ELECTRIFICATION.—DIAGRAMS ILLUSTRATING REPULSION MOTOR PRINCIPLES.

ture reaction on the field. In addition, the latter has a neutralising effect on the sparking voltage. The field consists of six poles, the coils being of copper bars suitably insulated, connected at the ends by straps.

The use of the repulsion-starting principle is an important feature of the installation. Hitherto it has not been the practice to short-circuit the armature of an A.C. commutator motor, and the adoption of this plan is of more than passing interest.

The invention of the repulsion motor is due to Prof. Elihu Thomson, who more than twenty-five years ago developed the scheme shown diagrammatically at A in the diagram. This represents a two-pole motor having field coils wound on laminated field cores and connected to an A.C. supply line, an armature with brushes and coils connected to the commutator bars as in a D.C. motor, and a connection short-circuiting the brushes. The brushes are shifted from the normal position as shown.

If the brushes were placed under the middle of the field poles, the magnetic field flux would pass transversely through the spaces inclosed by the armature coils, and a current would flow between brushes, because the passage of alternating magnetic flux through a loop of wire sets up current flow in the wire, in accordance with the well-known principle on which a transformer operates. The short-circuiting of the brushes would permit a current that would be limited only by the impedance of the electric circuit. This flow of current in the short-circuited coils would set up torque, because each conductor would be within a magnetic field. No net torque would be produced, however, because the current would flow in the armature conductors in opposite directions on opposite sides of the brushes and the torques produced on the two sides of the armature would balance each other. But if the brushes are shifted as shown in diagram A, the balance is disturbed and net torque is produced, because the torque of

the windings on one side of the brushes overcomes the lesser torque of the windings on the other side.

The principle of the repulsion motor can be explained also by means of the second diagram, shown at B. This motor is equivalent in every way to the preceding. Here the winding is represented as divided into two parts, main and auxiliary coils, one furnishing the field for the production of torque and the other inducing the armature current. It is evident that the compensating winding used in the A.C. series motor, shown crudely in principle in C, could be used as an auxiliary winding, to produce a shifting of the magnetic field equivalent to a shifting of the brushes. A series motor can therefore be readily adopted to repulsion starting.

In the Philadelphia-Paoli motor the original scheme of Professor Thomson is still further modified by the addition of the series connection of armature and field. The armature and field windings are therefore both "conductively" and "inductively" connected. To the extent, however, that current is induced in the short-circuited armature because of the transformer effect of the auxiliary winding it is a repulsion motor. On account of the low resistance of the armature short-circuit the induced current during the starting period has a high value.

VALIDITY OF PRE-WAR POWER CONTRACTS

A N interesting action in regard to power supply contracts is pending between Messrs. Taylor & Farley and the West Bromwich Corporation. The matter was before Mr. Justice Neville in the Chancery Division on Friday, when an injunction was asked for restraining the Corporation from carrying out a threat to restrict or cut off altogether the supply of electricity at present being given. It appears that a contract was entered into on November 13th, 1912, under which the Corporation was to give a supply of electrical energy at 480 volts for five years at an agreed price per unit on the understanding that a minimum of 80,000 units per annum would be taken.

As a result of the increased cost of fuel since the war started the Corporation had already increased the charges to its ordinary power consumers by 20 per cent., and has just increased them by a further 15 per cent. At the time this second increase was made the Corporation informed Messrs. Taylor & Farley that, as they were demanding a far larger quantity of electricity than was anticipated at the time their contract was entered into—the firm is now taking at the rate of 200,000 units per annum—it was proposed to increase the price under the agreement by 20 per cent., and that in the event of the Company not agreeing to this increase the amount of energy supplied would either be reduced or cut off altogether, as might be most convenient to the Corporation. It was subsequently threatened that from December 20th the supply would be cut off between 4 p.m. and 6 p.m. each day.

When the case came before the Court it was claimed on behalf of Messrs. Taylor & Farley that the Corporation is bound by the agreement of 1912, and further that any curtailment of the supply would be a serious matter, having regard to the nature of the work now being carried out by them.

Mr. Justice Neville granted an interim injunction extending over Christmas, until the first Friday of the next sittings, when the matter will again be mentioned.

Northampton Institute.—The annual prize distribution took place on Friday, the conversazione being abandoned this year. Dr. Mullineux Walmsley, the Principal, in his report refers to the reduction in the number of students owing to enlistment—no less than 226 students and 119 members of the Polytechnic, together with 22 members of the staff, having joined the Forces. Of these, 50 have obtained Commissions in one or other of the Services. On the whole, the work of the Institute followed more or less the usual lines, notwithstanding the depletion, the falling off in students being estimated at about 24 per cent. The work of the Polytechnic has continued to receive the cordial support of the trades affected, and for the eleventh year in succession it has been in a position to place, without payment of premiums, the whole of the second and third year engineering students in commercial workshops for the summer. As a matter of fact, this was easier than usual, because by Easter the loss of skilled workers was making itself felt in all engineering trades.

Enemy Patents.—The Board of Trade have made an order permitting persons living and carrying on business in the United Kingdom to pay the fees for obtaining the grant of, or renewal of, "enemy" patents, or for obtaining the registration of designs or trade marks or renewals of same and to pay enemy agents their charges and expenses. Similarly it is permissible to pay on behalf of an "enemy" fees due in converse circumstances.

THE OSRAM v. POPE PATENT ACTION

Chancery Judgment Confirmed

A S briefly announced on p. 497 of our last issue, the Appeal Court has upheld the judgment of Mr. Justice Joyce in the Chancery Division that the process used in the manufacture of Pope metal filament lamps does not infringe the Osram patents. Mr. Justice Joyce's judgment was given on p. 311 of our issue for July 22nd, and the proceedings in the case were reported in our issues for July 1st, p. 283; July 8th, p. 294; and July 15th, p. 304. The Appeal Court consisted of the Master of the Rolls (Lord Justice Cozens-Hardy) and Lords Justices Warrington and Bankes. When the judgment was given on Wednesday last week, however, the Master of the Rolls was not present, but he intimated, through Lord Justice Bankes, that he concurred in the finding of his colleagues.

The patent which the Osram Lamp Works had alleged was infringed was that of Just & Hanaman, No. 23,899 of 1904, and the material parts for the purpose of the action are as follows:—

For the manufacture of filaments of this kind finely divided tungsten or tungsten compounds such as tungstate, tungstic acid, or tungstic sulphide are mixed with an organic binding medium, such as collodion or a solution of cellulose in chloride of zinc or cupreous ammonia oxide or the like, from which mass filaments are formed in the usual manner, and are then carbonised, in some instances after denitration has previously been effected. The filaments so produced and consisting of tungsten and carbon are then submitted to the following further treatment.

First of all the carbon, which has only served as a binding medium, is removed by subjecting the filaments to the passage of current in an atmosphere of steam and hydrogen, and thus raising it to a high temperature. By this process the carbon is completely oxidised so as to form carbonic oxide and a filament of tungsten is left. These filaments are then rendered uniform in a manner similar to that employed in the treatment of the usual carbon filaments, by submitting them to the action of current in an atmosphere of volatile tungsten compounds in the presence of a large quantity of hydrogen whereby the tungsten deposited equalises the filaments. The filaments which have been rendered uniform in this way are then sealed in glass bulbs in the usual manner, and these latter are exhausted.

Mr. Justice Joyce held that the Pope Co. do not use any of the processes of carbonisation set out in the patent, nor do they use an atmosphere of steam and hydrogen in the sense in which the phrase was used in the specification or was intended by the patentees. Indeed, he did not think the defendants used steam at all in the ordinary sense.

Lord Justice Bankes, in his judgment, detailed the steps followed in the Pope Co.'s process as set out during the proceedings before Mr. Justice Joyce, and then pointed out the main points on which the two processes differ. In the first place, he said, the Just-Hanaman process involved the use of a soft material, whereas in the Pope process a hard material was used. In the second place, carbonisation under the patent was done separately and before any attempt was made to decarbonise, whereas in the Pope process carbonisation and practically the whole of the decarbonisation are done at one and the same time in the first furnace or in the vacuum, as the case may be. In the third place, the heat necessary for the decarbonising part of the process as described in the patent was produced by passing an electric current through the filaments, whereas the Pope Co. applied the heat externally. In the fourth place, under the patent the filaments were exposed to a previously prepared atmosphere of steam and hydrogen, which was not the case in the Pope process. In some respects the differences might be differences of degree rather than of kind, but, having considered the question whether the defendants' process as a whole, and having regard particularly to the four points indicated above, was substantially the same as the process set out in the patent, he was of the opinion that it was not. In his view, the differences passed the border line which separates a difference in degree from a difference in kind, and the process as a whole was, in his opinion, substantially different from the one described in the patent. Therefore the appeal failed, and would be dismissed with costs.

Lord Justice Warrington, who concurred, said that the process used by the Pope Co. started from a different standpoint to that of the patent. The several steps in it were different in nature and had different aims and results, and the variations in it, as compared with the patent, were not merely colourable alterations.

At the conclusion of the reading of the judgments Mr. A. J. Walter, K.C., for the Osram Co., said he presumed the Court would not grant a stay.

Lord Justice Bankes: No.

RECENT DEVELOPMENTS IN INCANDESCENT LAMPS

AT the Illuminating Engineers' Society on Tuesday last week a discussion took place upon recent developments in electric incandescent lamps in relation to illuminating engineering. Professor Silvanus P. Thompson, F.R.S., was in the Chair.

Dr. J. T. Morris opened the discussion, and after tracing the history of the electric incandescent lamp from the earliest Swan lamp, dealt at some length with the tendency to adopt horizontal spiral filaments instead of the vertical hair-pin type. One advantage of these, he said, is that the light can be controlled more easily, although his experience had been that the life is something like 20 per cent. shorter. This, however, he did not regard as serious, because the cost of current in a lighting installation was very much larger than the cost of lamps, and even with a life of only 200 or 300 hours the total running cost of an installation might be less than with the older type of filament on account of the greater efficiency of the spiral filament. Professor Morris described the new arc-incandescent lamp which is now being developed by the Ediswan Co.; this was described in our issue of Dec. 9th, and is further illustrated this week. In this connection tests of the relation of candle-power to voltage which Professor Morris has carried out are interesting. Whereas with the carbon filament lamp a 1 per cent. change in voltage usually means a 6 per cent. change in candle-power, with the new arc-incandescent lamp the change of candle-power with 1 per cent. variation in voltage is only $\frac{1}{4}$ per cent. Finally Professor Morris made a suggestion that with these new forms of spiralled filament lamps a polar curve should be given on the wrappings they are sold in, so that the purchaser would have a good idea of what the candle-power was supposed to be in particular directions.

Following Professor Morris's remarks, Mr. S. R. Mullard exhibited and demonstrated the new arc-incandescent lamp of the Edison & Swan Co., and pointed out that they have been made in the laboratories up to 1,200 candle-power, both electrodes being of tungsten.

Mr. F. W. Willcox (British Thomson-Houston Co.) discussed in some detail the change in designs and character of fittings necessitated by the introduction of the half-watt lamp in particular, and spiralled filament lamps in general, but did not share Professor Morris's view that this type of filament would necessarily replace the vertical filament. This could only be, he said, if there was greater efficiency, as in the case of the half-watt lamp. Being a much shorter filament, the spiral was bound to be much hotter, and consequently the life shorter.

Several other speakers took part in the discussion, including Mr. W. R. Cooper, who asked for further details of the arc-incandescent lamp; Mr. A. E. Cunningham, of the London & South Western Railway Co., who raised the question of the necessity for standardising the expression of the candle-power of these new forms of lamps, and also discussed the advantages of under-running half-watt lamps; Mr. E. Stroud, of the Holophane Company, who disagreed with Mr. Willcox that it is necessary to have special reflectors for half-watt, and horizontal filament lamps, although he agreed that greater care is necessary in adjusting the position of the lamp in the reflector in order to get the illumination in any desired direction; and Mr. L. Gaster, who urged manufacturers not to push these new forms of lamps until they are absolutely satisfactory from every point of view.

In winding up the discussion, Professor Silvanus Thompson twitted manufacturers in connection with the high prices now charged for incandescent lamps, which, he said, he was quite certain was very much higher than they need be.

The Institution and Enemy Members.—The *Journal* of the Institution of Electrical Engineers for December 15th states that representations have been made to the Council by certain members to the effect that members of enemy origin and nationality should be excluded from membership. It is pointed out, however, that the Council is legally advised that the only powers of expulsion which the Institution or its Council appears to have are those contained in Article 41 of the Articles of Association. May we remind the Council, however, that there is nothing to prevent, if it is thought advisable, the Articles of Association being revised at a special general meeting of the members? A letter on this subject appeared on p. 492 of our issue for December 9th.

The B.E.A.M.A.—The following firms have recently been elected members of the B.E.A.M.A.: Cole, Marchent & Morley; Hick, Hargreaves & Co.; The Edison & Swan United Electric Light Co.

THE REPULSION-STARTING TRACTION MOTOR

THE adoption of single-phase power supply with repulsion-starting series motors, for the electrification of the suburban line of the Pennsylvania Railroad at Philadelphia, marks a new step in the progress of electric traction. The electrified section of this railway, which is described at length in the *Electric Railway Journal*, is about 20 miles long, and the rolling-stock consists of 93 all-steel cars, all equipped as motor cars.

Each car is provided with two 225-h.p. Westinghouse single-phase, air-blast-cooled motors, mounted on one truck. All the main electrical apparatus is placed at one end of the car, and the brake equipment at the other, giving about 60 per cent. of the total car weight on the driving wheels. The motors are connected in series, and are started and operated up to 15 miles per hour as repulsion motors, with the compensating field, the armature, and the main field in series. With these series connections the armature is short-circuited through resistance. Resistance is also inserted in series with the motors on the first step, and is cut out on the second step. The third step changes the connections to energise the compensating field from one portion of the transformer, and the armature and main field in series, from another portion, thus affording doubly-fed connections. The armature short-circuit is removed when the motors are operating with the double feed. Subsequent steps in the control serve to increase the motor voltages.

Each motor has a continuous rating of 200 h.p. when ventilated with 1,200 cu. ft. of air per minute. The armature is of standard construction; the commutator and the laminations are mounted on the spider, the former being undercut 1/16 in. The armature is wave-wound and cross-connected, and no resistance leads are used between the windings and the commutator. The field windings consist of two entirely independent sets of coils, one being the main field circuit for producing the effective magnetic field, and the other the auxiliary or compensating winding which balances the arma-

the windings on one side of the brushes overcomes the lesser torque of the windings on the other side.

The principle of the repulsion motor can be explained also by means of the second diagram, shown at B. This motor is equivalent in every way to the preceding. Here the winding is represented as divided into two parts, main and auxiliary coils, one furnishing the field for the production of torque and the other inducing the armature current. It is evident that the compensating winding used in the A.C. series motor, shown crudely in principle in C, could be used as an auxiliary winding, to produce a shifting of the magnetic field equivalent to a shifting of the brushes. A series motor can therefore be readily adopted to repulsion starting.

In the Philadelphia-Paoli motor the original scheme of Professor Thomson is still further modified by the addition of the series connection of armature and field. The armature and field windings are therefore both "conductively" and "inductively" connected. To the extent, however, that current is induced in the short-circuited armature because of the transformer effect of the auxiliary winding it is a repulsion motor. On account of the low resistance of the armature short-circuit the induced current during the starting period has a high value.

VALIDITY OF PRE-WAR POWER CONTRACTS

AN interesting action in regard to power supply contracts is pending between Messrs. Taylor & Farley and the West Bromwich Corporation. The matter was before Mr. Justice Neville in the Chancery Division on Friday, when an injunction was asked for restraining the Corporation from carrying out a threat to restrict or cut off altogether the supply of electricity at present being given. It appears that a contract was entered into on November 13th, 1912, under which the Corporation was to give a supply of electrical energy at 460 volts for five years at an agreed price per unit on the understanding that a minimum of 80,000 units per annum would be taken.

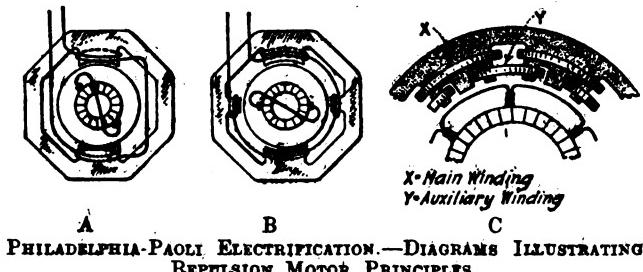

As a result of the increased cost of fuel since the war started the Corporation had already increased the charges to its ordinary power consumers by 20 per cent., and has just increased them by a further 15 per cent. At the time this second increase was made the Corporation informed Messrs. Taylor & Farley that, as they were demanding a far larger quantity of electricity than was anticipated at the time their contract was entered into—the firm is now taking at the rate of 200,000 units per annum—it was proposed to increase the price under the agreement by 20 per cent., and that in the event of the Company not agreeing to this increase the amount of energy supplied would either be reduced or cut off altogether, as might be most convenient to the Corporation. It was subsequently threatened that from December 20th the supply would be cut off between 4 p.m. and 6 p.m. each day.

When the case came before the Court it was claimed on behalf of Messrs. Taylor & Farley that the Corporation is bound by the agreement of 1912, and further that any curtailment of the supply would be a serious matter, having regard to the nature of the work now being carried out by them.

Mr. Justice Neville granted an interim injunction extending over Christmas, until the first Friday of the next sittings, when the matter will again be mentioned.

Northampton Institute.—The annual prize distribution took place on Friday, the conversazione being abandoned this year. Dr. Mullineux Walmsley, the Principal, in his report refers to the reduction in the number of students owing to enlistment—no less than 226 students and 119 members of the Polytechnic, together with 22 members of the staff, having joined the Forces. Of these, 50 have obtained Commissions in one or other of the Services. On the whole, the work of the Institute followed more or less the usual lines, notwithstanding the depletion, the falling off in students being estimated at about 24 per cent. The work of the Polytechnic has continued to receive the cordial support of the trades affected, and for the eleventh year in succession it has been in a position to place, without payment of premiums, the whole of the second and third year engineering students in commercial workshops for the summer. As a matter of fact, this was easier than usual, because by Easter the loss of skilled workers was making itself felt in all engineering trades.

Enemy Patents.—The Board of Trade have made an order permitting persons living and carrying on business in the United Kingdom to pay the fees for obtaining the grant of, or renewal of, "enemy" patents, or for obtaining the registration of designs or trade marks or renewals of same and to pay enemy agents their charges and expenses. Similarly it is permissible to pay on behalf of an "enemy" fees due in converse circumstances.

PHILADELPHIA-PAOLI ELECTRIFICATION.—DIAGRAMS ILLUSTRATING REPULSION MOTOR PRINCIPLES.

ture reaction on the field. In addition, the latter has a neutralising effect on the sparking voltage. The field consists of six poles, the coils being of copper bars suitably insulated, connected at the ends by straps.

The use of the repulsion-starting principle is an important feature of the installation. Hitherto it has not been the practice to short-circuit the armature of an A.C. commutator motor, and the adoption of this plan is of more than passing interest.

The invention of the repulsion motor is due to Prof. Elihu Thomson, who more than twenty-five years ago developed the scheme shown diagrammatically at A in the diagram. This represents a two-pole motor having field coils wound on laminated field cores and connected to an A.C. supply line, an armature with brushes and coils connected to the commutator bars as in a D.C. motor, and a connection short-circuiting the brushes. The brushes are shifted from the normal position as shown.

If the brushes were placed under the middle of the field poles, the magnetic field flux would pass transversely through the spaces inclosed by the armature coils, and a current would flow between brushes, because the passage of alternating magnetic flux through a loop of wire sets up current flow in the wire, in accordance with the well-known principle on which a transformer operates. The short-circuiting of the brushes would permit a current that would be limited only by the impedance of the electric circuit. This flow of current in the short-circuited coils would set up torque, because each conductor would be within a magnetic field. No net torque would be produced, however, because the current would flow in the armature conductors in opposite directions on opposite sides of the brushes and the torques produced on the two sides of the armature would balance each other. But if the brushes are shifted as shown in diagram A, the balance is disturbed and net torque is produced, because the torque of

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 16th, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

23,113/14. **Renewable Lamps.** E. TERRY. Incandescent lamps with the filament supports mounted upon a removable stopper inserted in the neck of the bulb. Provision is made for exhausting through a passage in the neck, and mercury is made use of in keeping the plug airtight. (One figure.)

2,386/15. **Circuit-breakers.** B.T.-H. Co. (*G.E. Co., U.S.A.*) Circuit-breakers with a magnetic blow-out, the field for which is provided by pieces of magnetic material on both the fixed and moving contacts. (Two figures.)

5,943/15. **Switches.** G. GILES. An improved and simplified form of air-break high-pressure switch mounted on a single porcelain insulator, and having one or more auxiliary contacts carrying resistance to diminish the current as the circuit is being broken. (Four figures.)

8,458/15. **Conduit Joints.** F. W. URBN and A. GAMBLE. The sleeves, sockets, fittings, &c., are made with a series of longitudinal slots at the ends, and a sliding collar which can be drawn forward to tighten the slotted ends over the tube. The interior of the sleeve is roughened to tear the enamel off the tube as it is pushed in to ensure electrical continuity. Sharp projections on the clamping ring projecting through the slots may also be provided for the same purpose. (Five figures.)

9,158/15. **Cookers.** THE JACKSON ELECTRIC STOVE CO., LTD., R. C. GRIESBACH, H. H. HOLMES, C. H. SMITH, and F. H. WILLIAMS. Self-contained electric cooking utensils without flexible leads, arranged to plug into a "hob," with the contacts interlocked so that current cannot be switched on till the utensil is in the proper position for cooking, nor the utensil removed till the current is switched off. Further, the circuit can only be opened when the lowest valve of the current provided for by the various degrees of heat is on. (Five figures.)

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

DYNAMOS, MOTORS, AND TRANSFORMERS: DUCKHAM [Oil-cooled transformers] 9,110/15.

Incandescent Lamps: B.T.-H. Co. (*G.E. Co., U.S.A.*) [Exhausting lamps] 1,088/15.

Instruments and Meters: BRITISH WESTINGHOUSE ELECTRIC & MANUFACTURING CO., LTD. [Meters] 5,554/15; FAWSSETT [Temperature compensation of meters] 7,271/15.

Switchgear, Fuses, and Fittings: CURTIS, SHORT, and IGRANIC ELECTRIC CO. [Controllers] 23,171/14; WATSON, WATERS, and CALLENDER'S CABLE & CONSTRUCTION CO. [Protective system] 23,749/14; TORCHIO [Reactance coils] 3,433/15; MCRAE and

RUSSELL [Arc deflector] 8,303/15; SOC. GÉNÉRALE DES CONDENSATEURS ELECTRIQUES [Excess voltage protection] 15,148/15.

Telephony and Telegraphy: SOC. MARIUS LATOUR ET COMPAGNIE [High-frequency transformers for wireless telegraphy and telephony] 4,345/14; IMRAY (*Siemens & Halske A.G.*) [Telephone circuits] 939/15; MARKS (*Delany Foreign Co.*) [Telegraphic apparatus] 2,164/15.

Traction: BALLINGTON & SHAW [Signalling and train-stopping apparatus] 28,641/14; TURNER [Safety device for electric cars] 8,376/15.

Miscellaneous: GROVE [Magnetic compasses] 21,411/14; NEWTON and NEWTON BROTHERS [Magnetic clutches and brakes] 22,893/14; BENDIXEN and MOUNTAIN [Fire alarms] 23,726/14; BURDON (*Siemens-Schuckert Ges.*) [Galvanic batteries] 112/15; GOBY [Spark quencher] 1,612/15; CHARLEBOIS [Electromagnetic and vacuum lifters] 1,684/15; STERN [Signalling] 3,419/15; GUS and BRITISH EVER-READY CO. [Illuminated writing implements] 13,611/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Heating: CLEMENTS [Soldering irons] 16,452/15.

Electrometallurgy: COCHLOVIUS [Electric furnaces] 16,602/15. **Telegraphy:** SIEMENS & HALSKE A.G. [Spark gaps for wireless telegraph oscillatory circuits] 14,696/15.

Miscellaneous: SATINOVER [Electric fly-traps] 16,044/15.

Applications to Suspend or Avoid Enemy Patents

21,750/09, 24,389/10, 19,473/11, 16,165/12, 218/13, 1,179/13, and 25,180/13. **Th. GOLDSCHMIDT. Rail Welding.** Applications by The British Thermit Co., Ltd., relating to these patents, all of which have reference to the Thermit system of welding tramway rails *in situ*, will be heard to-morrow.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

26,340/01. **Controllers.** B.T.-H. Co. (*C. Holz, U.S.A.*). A blow-out arrangement for controllers of the tramway type, in which the field produced by the single blow-out coil embraces the whole range of the contact fingers.

26,344/01. **Cables.** B.T.-H. Co. (*W. Le R. Emmett and W. S. Clark, U.S.A.*). Cables insulated with varnished fabric with the successive layers arranged to break joint, and sealed at the joints by a viscous insulating medium.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps, &c.: A. G. BLOXAM [Arc lamp electrodes] 20,311/09.

DYNAMOS, MOTORS, and TRANSFORMERS: M. WALKER [Split-pole machines] 18,870/02; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Centrifugal clutches for single-phase induction motors] 18,369/08.

Electrochemistry and Electrometallurgy: J. Y. JOHNSON (*Badische Anilin & Soda Fabrik*) [Arc furnaces for treating gases] 20,129/09.

TRACTION: SIEMENS BROTHERS DYNAMO WORKS [Supports for overhead conductors in tunnels] 18,222/08.

return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,474.

Describe in detail the best practical methods used to-day for boosting up the voltage of defective individual cells in a battery. What is the cause of, and remedy for, this defection of single cells?

(Replies must be received not later than first post, Thursday, Dec. 30th.)

ANSWERS TO No. 1,472.

When replacing an E.H.T. 3-phase switch (which had accidentally been tripped) it was noticed that the reading on the switch ammeter went up to nearly 20 amps., and then gradually died down to almost zero. The current was switched on to

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the

two transformers, a 100 and a 50 k.v.a. respectively. What would cause the momentary excessive rise in current? On another occasion, when switching in, there was no rise whatever on the ammeter beyond the transformer current. Is such a rise in any way bad for the transformer from a practical or theoretical point of view?—H. H.

The first award (10s.) is given to "Alpha" for the following reply:—

Under normal conditions the flux in an unloaded transformer supplied with a sine wave of E.M.F. will be represented by a sine wave lagging 90° behind the E.M.F., and the magnetising current by an alternating wave also lagging nearly 90° , and more or less peaked according to the degree of saturation of the transformer iron. If the switch connecting the transformer to the line is closed at the instant of the maximum value of the E.M.F. and there is no residual magnetism in the transformer, the flux and magnetising current both start from zero, as shown in the top left-hand diagram of Fig. 1, and the transformer takes its normal magnetising current at once. If, however, the switch is closed

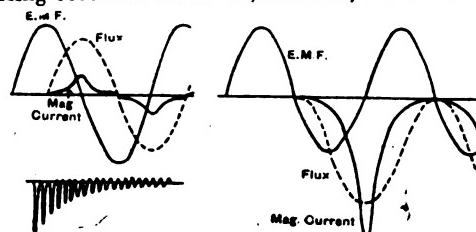

FIG. 1.

when the voltage is zero (see the right-hand diagram), it is evident that the flux wave will still start from zero (assuming no residual magnetism), although at this point of the voltage wave it would normally be at a maximum. Since the total change of flux is the same for a given E.M.F. cycle, the maximum value of the flux will reach double its normal maximum at the end of the first half cycle. This means that the magnetic density in the transformer iron will reach, say, 150 kilolines per sq. inch instead of the normal value of, say, 75 kilolines, i.e., the iron will be highly saturated, and the magnetising current correspondingly great, perhaps 20 times normal current.

At the end of the first cycle the flux and magnetising current will have returned to zero, and the magnetising current will therefore consist of a pulsating, unidirectional wave, rising (due to the high saturation) to a very high value. This may be considered as a transient, pulsating current superimposed on the normal magnetising current, and the effect of the losses in the transformer is to gradually damp out the transient current, so that the magnetising current after a few cycles will have dropped back to its normal condition, as indicated in the smaller diagram on the left, which is drawn to a smaller scale. If there is any residual magnetism in the core at the instant of switching on, the total change of flux must still remain the same, so that the maximum value reached will be either increased or decreased, depending on the direction of the residual. The effect of residual magnetism may therefore be to still further increase the saturation, and hence the magnetising current. From the above it will be evident that the reading given by the ammeter at the instant of switching on will depend on the point of the voltage wave at which the switch makes contact, and also upon the amount and direction of the residual magnetism in the transformer iron.

Since the normal magnetising current of a transformer may be taken as about 5 per cent. of the full load current, a rush of twenty, or even thirty, times this amount will not be sufficient to cause overheating or mechanical damage, and it may therefore be considered harmless to the transformer, although the writer knows of at least one case where the switching of a large transformer on to a comparatively small supply caused sufficient disturbance to trip the generator oil-switch and interrupt the supply.

In addition to the above effect there will be a high frequency current at the moment of switching on, due to the distributed capacity and inductance of the transformer windings. This will, however, be of much too high a frequency to give a reading on an ordinary ammeter, and is quite negligible except on circuits of, say, 50,000 volts and over, where it may cause a breakdown of the transformer insulation. At lower voltages than this the distributed capacity of the windings is practically nil.

The second award (5s.) is given to "S. A. S." for the following reply:—

The explanation of the excessive current rush at the instant

of switching in the three-phase transformers mentioned by "H. H." is as follows:—

The value of the current rush at the moment of switching in is principally determined by the point on the voltage wave at which switching occurs. The flux, being 90° out of phase with regard to the voltage, will attain to its maximum value when the voltage is zero, and vice versa. Now suppose the instant of switching in occurs when the voltage wave is at its zero value, and the flux consequently at its maximum. To produce any half-cycle voltage wave (say, zero to zero) it is necessary that the flux varies from a maximum negative to a maximum positive, thus embracing a total number of lines equal to twice the maximum induction. At the instant previous to switching there was no flux in the transformer circuit. But as soon as contact is made by the switch a flux must be set up which will uphold the voltage generated, and it is obvious that this flux must start from zero, since there is no flux in the transformer cores (assuming no residual magnetism). And that, further, the flux must also reach a value above zero equal to twice the maximum induction. Fig. 2 shows the voltage and flux waves from the instant of

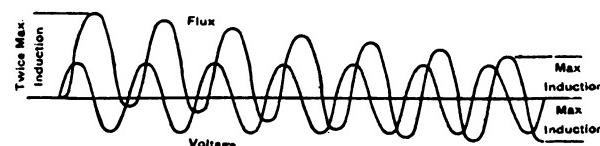

FIG. 2.

switching in till the flux adjusts itself to the normal conditions. It will be seen that the first half-cycle fulfils the above conditions, since the rate of change of flux is unaltered, and therefore the voltage is upheld. Since there is a definite ohmic drop in the circuit, however, the flux will not continue to pulsate equally as in the first half-cycle, but will rapidly adjust itself to the normal positive and negative value, as shown in the succeeding cycles.

Now by referring to Fig. 3, which shows a typical B-H

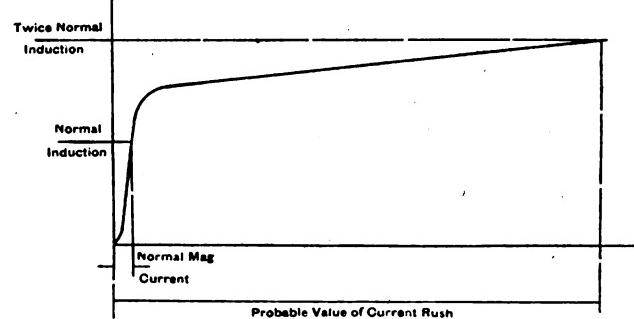

FIG. 3.

curve for commercial transformer iron, it will be seen that with a maximum induction of twice the normal the magnetising current will be increased out of all proportion. The current corresponding to this high induction is the value noted on the switch ammeter, and may reach to many times the normal full-load current. The rush of current will, of course, die down, as noted by "H. H.", due to the rapid adjustment of the flux.

If switching in had occurred when the voltage wave had its maximum value, no rise in current would have been recorded. The flux value corresponding to maximum voltage would be zero, and since there was no flux in the transformer cores there would be no tendency towards instability. The flux attains to its normal positive and negative values, and the current flowing is the normal no-load current.

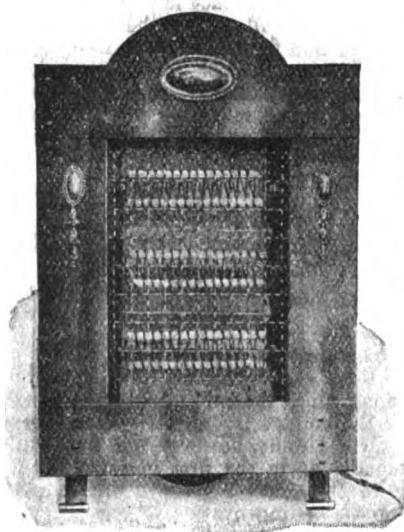

The current rush may attain to a larger value if the transformer cores contain residual magnetism, since the maximum induction will be increased by the number of lines positive remaining in the cores at the moment of breaking the circuit. If the residual magnetism is negative, then conversely the current rush may be smaller.

Trouble may result from severe current rushes, principally due to the heavy mechanical stresses set up between coils, and also to high voltages generated.

Rugby Engineering Society.—It has been decided that no papers or lectures will be given this session, in view of the fact that the time of the officials and members is largely occupied with war work, and that, owing to so many members having joined his Majesty's forces, the effective membership is greatly reduced. As far as possible the officials who were elected for session 1914-15 will continue to serve for the present session. In view of the above, the subscription will be reduced to 2s. 6d. for the present session.

DOWSING HEATING AND COOKING APPARATUS

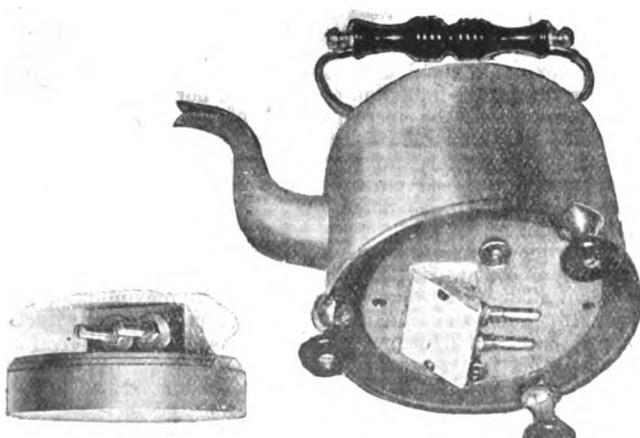

THE Dowsing Radiant Heat Co., Ltd. (39/40 York Place, Baker Street, W.), has issued a new and very complete list of electric radiators and heating apparatus. This firm, which has been making electric radiators for the past 20 years, originated the luminous system of heating, and subsequently non-luminous and bare-wired types of heaters. Special attention may now be called to the various new types of hot-bar radiators, and to a radio-convector pattern of heater. These radiators act in precisely the same manner as hot-water radiators, i.e., the air is warmed by coming into contact with

DOWSING ELECTRIC FIRE.

a heated surface. For this purpose two luminous heat lamps are used with non-luminous heaters. One of our illustrations shows a non-luminous type of heater, the three heating elements of which are each wound to take half a unit per hour, and are guaranteed for one year. Two switches are provided, thus giving three heats.

The firm has also introduced a new rap'd boiling kettle fitted with the Dowsing & Huntley interchangeable heating element. This element, shown in another illustration, is arranged to give a maximum amount of heat in a small area; it has extremely long life, and is quite interchangeable for

INTERCHANGEABLE HEATING ELEMENT.

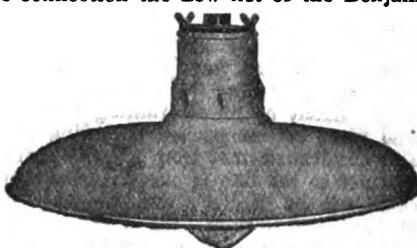

RAPID BOILING KETTLE.

various voltages. It is made under the Eastman & Warne patents, and is capable of being heavily loaded. This heating element is also applied to urns and other electric heaters. The list contains numerous types of heaters of all forms, and a smaller pamphlet deals with electric cookers, irons, grills, &c.

We may take this opportunity of pointing out the fact that, besides taking over Messrs. Eastman & Warne's business last year, the Dowsing Radiant Heat Co. recently purchased the Phoenix Electric Heating Company's business, i.e., good-will and useful stock, and have now also acquired the good-will, patterns, and secret processes for the manufacture of heating elements, drawings, and stock of heating elements of the British Prometheus Co., of Birmingham and London.

HALF-WATT LAMP FITTINGS

AS was pointed out at the last meeting of the Illuminating Engineering Society, reported on another page, the introduction of the half-watt lamp has rendered necessary considerable changes in design of reflectors and lamp fittings, and in this connection the new list of the Benjamin Electric,

DISTRIBUTING FITTING.

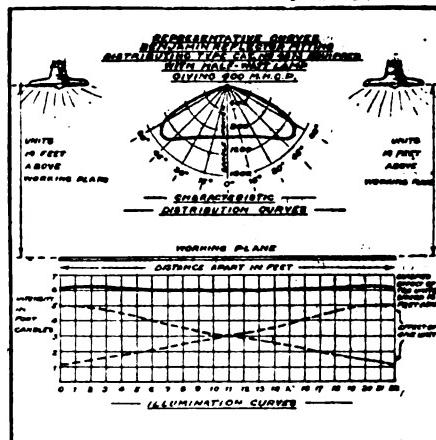

Ltd. (1A Rosebery Avenue, E.C.), is worthy of special notice. Not only is it a trade list giving prices and the usual particulars, but a quantity of valuable illuminating engineering data is given, together with definitions of terms, a method of

CONCENTRATING FITTING.

rapid calculation of illumination, and photometric curves of every type of fitting listed.

It is claimed that the range of fittings covered in the list is the most comprehensive yet produced, whilst the "Addenda" constitutes a remarkably simple form of refer-

PHOTOMETRIC CURVE OF BENJAMIN CONCENTRATING FITTING.

ence regarding the firm's apparatus. Our illustrations of distributing and concentrating types of fittings, together with a characteristic photometric curve, are typical of the large number dealt with in the booklet.

The Proposed State Control of Electricity Supply in Saxony.—According to the *Frankfurter Zeitung* of December 12th, 1915, the proposal of the Government of Saxony to create a State control of electricity supply is favoured by the Conservative party, and is certain to pass the First Chamber, while the attitude of the Second Chamber is uncertain. The scheme, if carried out, will cost the State about 58 million marks (£2,900,000), and comprises the purchase of a number of supply undertakings of various sizes, the erection of two or more large steam power stations, and the construction of an extensive 100,000-volt transmission and distribution system. The first power station will be erected at Regis, near Leipzig, and will cost about £500,000. A second in the neighbourhood of Dresden will cost about £650,000. The 100,000-volt transmission and distribution system is estimated to cost £500,000. Large coalfields near Regis and Dresden respectively have already been acquired by the Government.

THE TUNGSTEN ARC LAMP

THE Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex, and 123-125 Queen Victoria Street, E.C.), are now putting on the market the first form of tungsten arc lamp described in our issue of December 9th. This is intended for projector lanterns, and is illustrated in

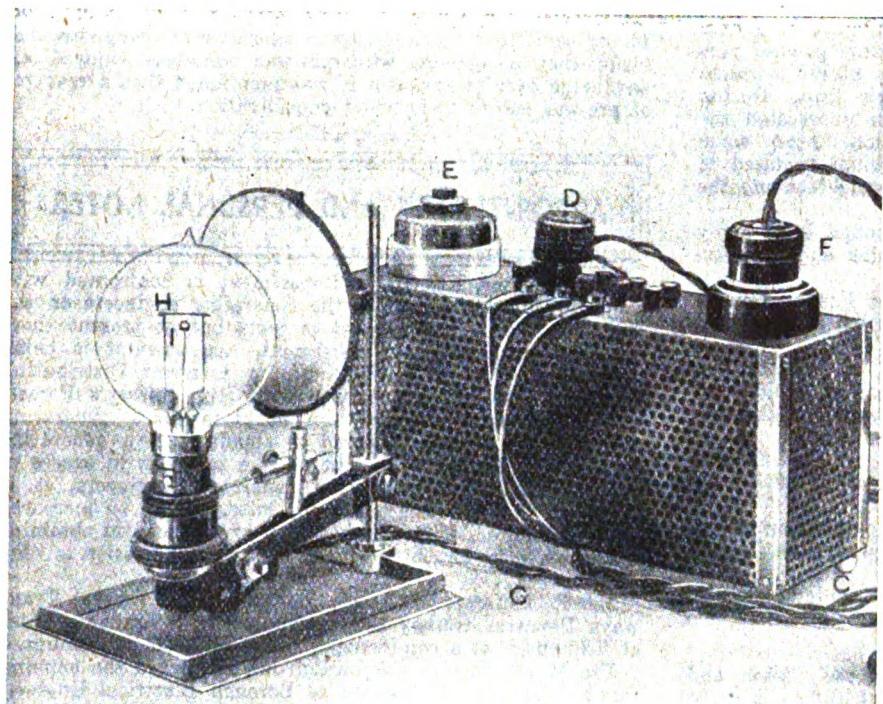

FIG. 1.—LAMP READY TO BE INSERTED IN LANTERN.

Figs. 1 and 2. The plug on the right of the resistance box in Fig. 1 is connected to an ordinary wall socket or pendant lamp through an adaptor. Three wires connect the lamp to the resistance, and when the push on the right-hand side of the resistance box is pressed it causes the ionising filament in the lamp to glow. The arc strikes almost immediately

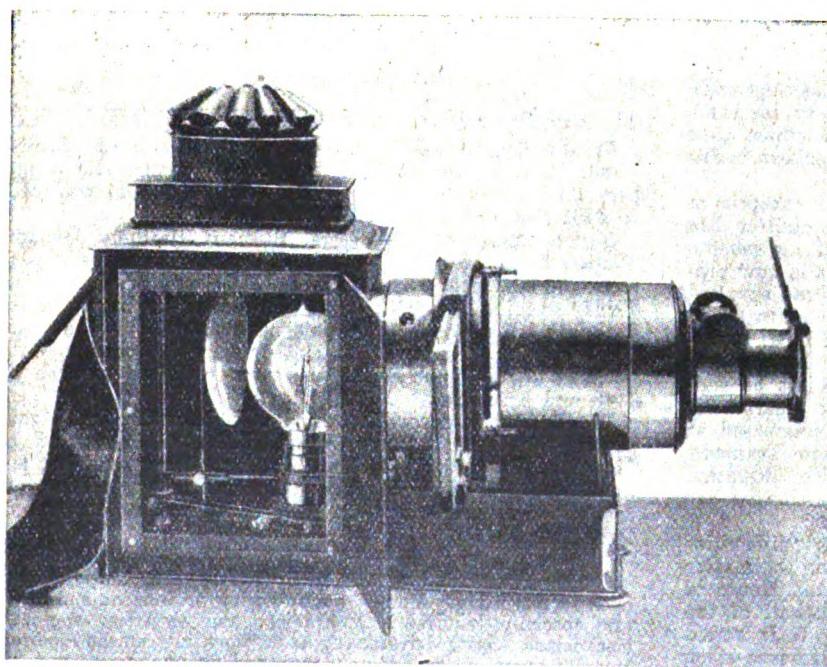

FIG. 2.—LANTERN READY FOR USE.

and the push must then be released. It is necessary to connect the lamp up with the correct polarity. The resistance box is so arranged that by means of the two-prong plug seen in the middle of the box it can be used for any voltage from 100 to 250 D.C. The lamp has been given the name of the "Pointolite" lamp.

THE "O.K." DRY CELL

WE have received from the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex, and 123-125 Queen Victoria Street, E.C.), a sample (taken from stock) of their Ediswan "O.K." dry cell, with the request that we should try it and give our opinion of it. A good dry cell should have two characteristics: It should be capable of supplying moderately large currents for some seconds, or possibly one or two minutes, at a time with only a moderate amount of polarisation and quick recovery; and it should keep in good condition without "drying up" for several months if employed only for intermittent currents of short duration with long periods of rest. As the latter property would obviously require some time to test, we decided to make a rough trial of the former one only, taking the simplest piece of apparatus nearest to hand for the purpose, viz., a small electric torch lamp.

The cell is of the ordinary "No. 2" shape and size, viz., 6 ins. high by $\frac{1}{4}$ ins. diameter, and the lamp used for the rough test, which was rather qualitative than quantitative, was a metal filament miniature lamp with a marked nominal rating of 2.25 volts and 0.17 amp.

On connecting the lamp to the terminals of the cell we obtained a good yellow glow—as is well known, such lamps are very much over-run, and give an extremely blue light at their marked voltage. We left the lamp connected to the cell for 10 minutes, without being able to observe any diminution of the light at all, so that it was apparent that some more drastic treatment was necessary. The following is the course of the "test" which we applied:—

Connected to lamp for 10 minutes.—No diminution of light.

Dead short-circuit for 1 minute.—No diminution of light.

Dead short-circuit for 2 more minutes.—Light very slightly reduced, but colour still yellow; lamp left on for 3 minutes and light improved slightly.

Dead short-circuit for 5 minutes.—Lamp only slightly fainter.

Switched off for 2 minutes, and then switched on. Lamp glowed almost at original brilliancy.

Lamp continued at original brilliancy, and after 2 minutes the cell was again short-circuited, this time for 10 minutes, and was then given 30 seconds' rest. The lamp still glowed with a yellow colour, and after one minute's rest was again short-circuited for 10 minutes. After this the lamp still glowed with a fairly good yellow colour.

Switched off battery for 8 hours' rest, after which the lamp was again switched on for two minutes and continued to glow as brightly as at the very start.

Short-circuited for 5 minutes.—Lamp still glowed, with slightly reduced brilliancy.

Eleven hours' rest.

Lamp switched on again and left on for 4 hours. Light practically as good as at the very first all the time.

Fourteen hours' rest.

Lamp switched on again, and left on for 8 hours. Light still maintained at practically the same brilliancy.

Short-circuited for 30 minutes, after which lamp glowed a dull red only.

Rest for 1 minute. Lamp glowed much brighter.

Rest for 3 more minutes. Lamp glowed at same brilliancy as before last short-circuit.

Rest for $8\frac{1}{2}$ hours.

Lamp reconnected for 30 minutes and glowed all the time at the same brilliancy as at the very start.

After this we thought it unnecessary to continue the trial, being quite satisfied that the cell certainly is "O.K." It undoubtedly complies with the first characteristic set out above, and we may have something to say about its durability later on.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Kingston.—A Local Government Board inquiry was held last week concerning a loan of £16,792 for the general purposes of the electricity undertaking. Of this £5,792 is excess expenditure, leaving £11,000 as actual new loan. During the course of the proceedings the Inspector deprecated the policy of spending money without sanction. After some discussion it was agreed to reduce the amount required to £3,307, this being sufficient to carry on for eighteen months instead of four years.

London.—The Hammersmith Borough Council is to apply for a loan of £3,000 for extensions to mains and services, transformers, &c.

Islington.—The Finance Committee of the London County Council recommend sanction to a loan of £985 for electrical purposes.

St. Pancras.—The Finance Committee of the London County Council recommend sanction to a loan of £15,000 for a new turbo-generator, subject to an acceleration in the rate of repayment of certain outstanding 42 years loans.

Marylebone.—The Finance Committee of the London County Council recommend sanction to a loan of £3,800 for mains and services.

New Zealand.—The Gisborne Council contemplate an expenditure of £10,000 upon electric light and power installations and £90,000 upon tramways.

The installation of a new generating set is contemplated by the Wellington Tramways Department.

Miscellaneous

Spain.—The conversion to electricity of one 25-ton and seven 3-ton steam cranes on the wharves at Bilbao is to be carried out. Full particulars from Juntas de Obras del Puerto, Alameda de Mazarredo 3, Bilbao.

LOCAL NOTES

Birmingham: Boiler Explosion.—The Board of Trade report upon the explosion of a water-tube boiler at Chester Street power house, which took place on August 28th last, shows that the accident was due to one of the tubes opening out through wearing thin. It appears that this tube had become thin in the ordinary course of usage, and it was suggested that a few others might be withdrawn and cut to ascertain their condition. At the same time the report states that care is taken at the power house to work the boilers under favourable conditions.

Brighton: Electricity Charges.—Owing to the exceptional increase in the cost of coal, the Electricity Committee has again been compelled to come to the Council with a scheme to increase the charges for electricity supply. It is now proposed that the flat rate of 4½d. per unit for current supplied to private houses, &c., for lighting should be increased to 5½d. per unit; that the special tariffs for arc lamps, advertising signs, outdoor and basement lighting, hotels, and public-houses be abolished, and that these premises be supplied on the new flat rate. In addition, the charge for current supplied outside the Borough is to be increased to 6½d. per unit, and the present charge to the Tramway Department from 1·35d. to 1·4d. per unit. No alteration is to be made in the maximum-demand system charges nor for street lighting.

Manchester: Coal Supply Difficulties.—The difficulties which the electricity department is encountering in the matter of a regular supply of coal were mentioned in the House of Commons last week, and Mr. Runciman, on behalf of the Board of Trade, promised to make inquiries. It is stated that owing to the necessity for drawing on the reserve stock this latter has now dropped from 21,000 tons at the end of the summer to 11,000 tons.

Walsall: Position of Electricity Undertaking.—In reporting an increased consumption of coal per unit generated, the Electricity Committee point out that this is only what had been expected from the conditions which have arisen since the war. Up to a certain point the increased demands made on the electricity undertaking assisted in increasing the efficiency, but owing to the inability of obtaining new

generating plant—the Minister of Munitions having commandeered a 3,000-kw. turbo-generator on order for the new power-house—old and inefficient machinery had to be brought into use. Hence the increase in the coal bill.

West Bromwich: Increased Charges.—It is interesting to note in connection with the statement on another page of this issue with regard to the proceedings against the Corporation by Messrs. Taylor & Farley, that at the last meeting of the Corporation some objection was taken to the increase of 15 per cent. in charges to power consumers. Complaint was made that consumers with pre-war contracts enjoyed an advantage over others, and it was mentioned that a revision of pre-war contracts is under consideration.

APPOINTMENTS AND PERSONAL NOTES

The Hackney Electricity Department is confronted with some difficulty in regard to the generating engineers on the staff. Ordinarily the number is four, but at present there are only two, owing to enlistment. An attempt is being made to get Mr. A. G. Hilling, the Assistant Distributing Engineer, released from service with His Majesty's Forces, and, if successful, to use him in place of a generating engineer. It is then proposed to appoint a new generating engineer, at £3 per week, but as this salary is in excess of that received by the existing generating engineers, it is suggested that the salaries of the latter should be increased to a like figure. Difficulty has been experienced in obtaining a suitable man for the position, hence the necessity to offer £3 per week.

Mr. E. Lafferty, the Traffic Manager to the Preston Tramways Department, has been appointed to a similar position at Edinburgh at a commencing salary of £300 per annum.

The Middlesbrough Corporation has confirmed the appointment of Mr. R. H. Scotson as Borough Electrical Engineer at a commencing salary of £300 a year.

Mr. E. Lunn has been appointed Station Superintendent in Huddersfield Electricity Department in place of the late Mr. Whitwam.

Foreman wanted for view room of firm of engineers under Government control. (See advertisement on another page.)

Switchboard attendant for provincial municipal supply and tramways undertaking. (See advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £100 to £101 (last week, £97 to £98).

Christmas Holidays.—Messrs. Siemens Brothers Dynamo Works, Ltd., inform us that the Lamp and Supplies Department (38-39 Upper Thames Street, E.C.) will be closed from Friday evening, the 24th inst., till Wednesday morning, the 29th inst. For stocktaking this department will also be closed on December 30th and 31st and January 1st, but in order to meet urgent requirements the counter will be open on the 29th and 30th inst.

The British Thomson-Houston Co., Ltd., notify that Mazda House (77 Upper Thames Street, E.C.) will be closed on Saturday, December 25th, and Monday, December 27th, and for the purpose of stocktaking on December 31st and January 1st. The counter, however, will be open for business on December 31st.

London Electrical Engineers, R.E. (T.F.).—This Corps is again open to recruiting. Men of the following professions and trades are specially required: Mechanical and electrical engineers, electricians, engine drivers, engine erectors, instrument repairers, metal turners, fitters, telephonists and telegraphists, and tinsmiths. There are a limited number of vacancies for carpenters, cabinet makers, pattern makers, draughtsmen, joiners, and wood turners. Forms of particulars can be obtained from the Officer Commanding at 46 Regency Street, Westminster, S.W.

Trade with Russia.—The Sales Managers' Association are making arrangements for sending a Commissioner to Russia in the early spring to make special reports and to put British manufacturers in communication with buyers in Russia. Official support of a valuable character has already been promised.

SUMMARY

At a recent joint meeting of the American Electrochemical and Illuminating Engineering Societies a Paper was read by Mr. W. A. Darrah describing a new form of tungsten arc lamp (p. 514).

THE Engineering Standards Committee has issued a specification for a standard plug and socket for charging electric vehicles (p. 514).

MR. J. R. BEARD has presented a Paper to the Institution of Electrical Engineers describing some most valuable and painstaking investigations into the design of high-pressure distribution systems based on results and observations in actual practice in the Newcastle and North-East Coast district. He included in the Paper a diagram, which we reproduce, showing the enormous extent to which the interconnection and duplication of high-pressure feeders is carried out in the above area (p. 515).

THE "James Forrest" lecture this year, written by Mr. H. M. Hobart, was read at the Institution of Civil Engineers by Mr. J. A. F. Aspinall, owing to the absence of the author in America. It dealt with electric traction on railways, and the conclusions arrived at are that we are on the eve of the extensive employment of electric locomotives on railways; that the direct-current system is the most appropriate; and that direct-current locomotives for use from high-pressure contact conductors are now a thoroughly demonstrated process (p. 516).

AT the last informal dinner of the B.E.A.M.A. the question of utilising the enormously increased capacity of engineering works—brought about by the war to good advantage when the need for munitions has passed was discussed (p. 517).

THE Engineering Standards Committee has issued a specification for 5-ampere wall plugs, making a plug with a 2-in. hand-shield the only standard (p. 517).

The insulation testing of a single-phase 3-wire network by means of a voltmeter is referred to in our Questions and Answers columns (p. 518).

AMONG the subjects of specifications published at the Patent Office last Thursday were production of high-frequency currents, motor control, feeder protection, and incandescent lamps (p. 519).

THE annual report of the Pacific Cable Board relates the story of the attack by the German cruiser *Nürnberg* and the resource shown by the staff in restoring communication after the cable had been cut and the ends dragged far apart (p. 519).

A NEW complete catalogue has been issued by Ferranti, Ltd. (p. 520).

A LOAN of £40,000 is to be taken up at Greenock; a low-tension switchboard is required at Manchester; and electrical plant for the Newton-in-Makerfield Gasworks (p. 522).

AN assisted wiring scheme is under consideration in Melbourne (p. 522).

A COMBINATION of important British electrical firms has been arranged for the purpose of developing the Russian market (p. 522).

ENGINEERING INSTITUTIONS' VOLUNTEER TRAINING CORPS

COMPANY ORDERS BY LIEUT.-COL. C. B. CLAY, V.D., COMMANDING.

Drills, 6.25 to 7.25; 7.25 to 8.25 p.m.

Sat., Jan. 1st: Uniform parade.

Mon., Jan. 3rd: Sections I. and II., technical. Sections III. and IV., squad. Signalling sections and recruits.

Tues., Jan. 4th: School of Arms with Architects Corps, 6 to 7. Thurs., Jan. 6th: Sections I. and II., shooting.

Fri., Jan. 7th: Sections III. and IV., technical. Sections I. and II., squad. Signalling sections and recruits.

Officer of the Week: Mon., Jan. 3rd, to Sat., Jan. 8th, Mr. L. C. Hughes Hallett.

Platoon on Duty: Mon., Jan. 3rd to Sat., Jan. 8th, No. 1 Platoon.

Sections for technical parade at Headquarters, London Electrical Engineers, 46 Regency Street, S.W.

Sections for shooting parade at miniature ranges.

Unless otherwise ordered all parades at Chester House.

Fatal Shocks from a Motor-car.—A most remarkable accident occurred at Eastbourne on Sunday last, as a result of which two men lost their lives. A Rolls-Royce car collided, without apparent cause, with a cast-iron H.T. switch pillar containing three switch fuses on a marble slab. It cut off the pillar flush with the ground, then charged a tree 2 ft. away, and stopped. All the occupants alighted without injury. Passers-by volunteered to push the car back, but in doing so brought the frame, which was insulated on the rubber tyres, in contact with one of the broken H.T. cables. As a result two men who were pushing the car fell forward on to the chassis. Policemen and others who tried in vain to remove them received severe shocks, and it was about fifteen minutes before the power station could be notified, the power cut off, and the men extricated. It was then found that life was extinct. The inquest has been adjourned in order that a representative of the Board of Trade may attend.

ANOTHER TUNGSTEN ARC LAMP

A TUNGSTEN arc lamp, made on slightly different principles to the one described in our issue of December 2nd, was the subject of a Paper presented by Mr. W. A. Darrah at a joint-meeting of the New York Section of the American Electrochemical and Illuminating Engineering Societies on November 11th. The author desired his Paper to be considered only in the light of scientific research, although, it is added by the *Electrical World* of New York, the results are very promising from a practical standpoint. In the report of the Paper published in our contemporary, the precise construction of the lamp is not quite clear in all its details, but a good deal of information is given, and we are glad to be able to re-publish it, together with the diagram below.

A study of the light efficiency of an arc from a chemical standpoint shows that there is a certain rather limited class of substances which when introduced into the arc in small quantities produce a very great increase in luminosity. Thus the addition of small quantities of cerium or calcium compounds to the carbon arc may increase its efficiency over 300 per cent., and the addition of titanium (preferably as an oxide) to the magnetite arc similarly produces an increased luminosity without a corresponding increase in energy consumption. But it is a peculiar coincidence that the addition of cerium or calcium to the magnetite arc, or of titanium to the carbon arc, does not result in approximately the same gain in efficiency. The chemical compound in which the element appears is apparently of little importance.

A study of these facts led to the conception that perhaps an

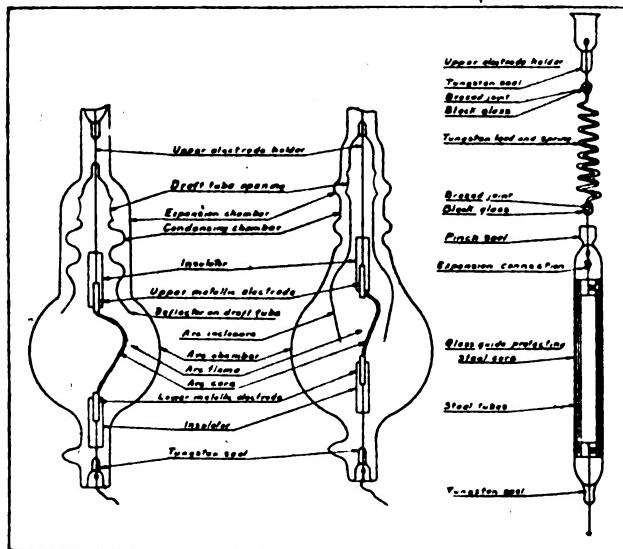

FIG. 1.

arc could be maintained in a closed vessel and supplied with these light-producing elements in the vapour form. The arrangement of the apparatus is shown in Fig. 1, which shows the latest designs. The lamp consists essentially of an arc chamber at the centre of which the arc is drawn between two tungsten electrodes about 3/16 in. in diameter. The electrodes are partly surrounded with a refractory insulator, designed to prevent the arc from moving far from the ends of the electrodes. Tungsten was found to be the most satisfactory electrode material, as it is practically inert, even at a white heat, in the presence of various vapours used.

As all the liquids employed for supplying the active vapour are hygroscopic, and many of them readily decomposed by ordinary moist air, it becomes necessary to exhaust the air from the lamp, heat the lamp and electrodes while at a low pressure in order to remove the air films, and then admit the liquids without opening the lamp chamber of the air. This was accomplished by means of a bottle sealed in the lower extremity of the lamp, and provided with a ground stop-cock connecting it with the lamp. After the proper degree of exhaustion was reached, the desired liquid was carefully poured into the bottles and the stop-cock opened slightly, when atmospheric pressure forced the liquid into the lamp chamber.

The appearance of the arc in this lamp is quite different from other commercial arc lamps. Among the vapours experimented with are antimony tetrachloride, carbon tetrachloride, stannic chloride, titanium tetrachloride, &c. The spectrum of the flame is usually quite different from the arc spectrum, and is characteristic of the elements

involved, while the spectrum of the arc independent of the ends of the electrodes (which, of course, give a hot-body spectrum) is usually a band spectrum, and is practically continuous except for a few absorption lines.

Fig. 2 shows performance curves giving the relation between arc length and voltage, and shows the rate at which additional arc lengths require an increased voltage. The curve is also interesting as indicating that a 4-in. arc at 10 amp. requires no more voltage than a 1-in. arc at 2 amp. In other words, a 10-amp. arc is four times as long; in addition, its intrinsic brilliancy is about five times that of a

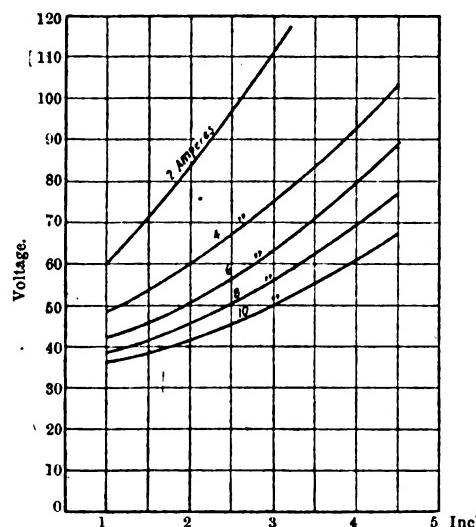

FIG. 2.—RELATION OF ARC LENGTH TO VOLTAGE.

2-amp. arc, and, accordingly, the light emitted by a 10-amp. arc under these conditions is twenty times that of a 2-amp. arc, and since the wattage of a 10-amp. arc is only about five times that of the 2-amp. arc, the efficiency is approximately four times that of the 2-amp. arc. Efficiency curves indicate that 20 amp. is approximately the point of maximum efficiency of this particular antimony pentachloride lamp.

It should be understood, however, that the current of maximum efficiency differs widely with differences in the nature and pressure of the gas as well as the volume and available radiating surface of the lamp, and very efficient titanium bromochloride lamps have been constructed with a maximum efficiency of about 5 amp.

A STANDARD CHARGING PLUG

In conjunction with the Electric Vehicle Committee of the Incorporated Municipal Electrical Association, the Engineering Standards Committee has issued a standard specification for a charging plug and socket for electrically-propelled vehicles. The design adopted is practically that illustrated in *ELECTRICAL ENGINEERING*, Vol. X., September 24th, 1914, p. 516. The object in view has been to standardise the essential details necessary to secure interchangeability between any charging plug and any socket of the design selected by the Electric Vehicle Committee, viz., concentric, leaving to them the issue of a detailed specification for the construction of the exact design of plug which, in their opinion, is best suited to the present needs of the industry. By doing so, it is felt that there will be as little interference as possible with invention and progress.

Wave-shapes of Alternators under Short-circuit.—A useful contribution to the theory of armature reaction is provided by a Paper by A. E. Clayton communicated to the I.E.E. and published in the Journal, on "The wave-shapes obtaining with alternating-current generators working under steady short-circuit conditions." The Paper is divided into four sections dealing with the ideal polyphase machine, three-phase, single-phase, and two-phase machines respectively. In each section salient pole and cylindrical field machines are considered, curves being given of magnetomotive force and flux distribution, e.m.f. in conductors, and the resulting e.m.f. per phase, and armature current. This subject serves as an excellent example of the properties of non-sinusoidal electromotive forces, and the difference in the wave-shapes of e.m.f.'s and the currents produced by them. Perhaps the most outstanding feature is the presence of marked third harmonics in the current wave of single-phase machines having a two-thirds winding.

DESIGN AND HIGH PRESSURE DISTRIBUTION SYSTEMS

AT the Institution of Electrical Engineers on December 6th, a Paper on the above subject was read by Mr. J. R. Beard (a member of the staff of Merz & McLellan). It had previously been read at Manchester, and was read at Cardiff on December 13th.

The Author referred to the growing tendency of splitting up the more extensive and cumbersome L.T. networks into several districts each fed by a separate sub-station, with the resulting increase in the size of high-tension distribution systems. One section of the Paper was devoted to a comparison of overhead and underground mains, and the Author stated that it was found in practice that the number of serious breakdowns of the former was only about double those on the latter; overhead mains are, however, more liable to transitory short-circuits causing temporary automatic disconnection of supply. For lower voltages—say from 3,000 to 6,000 volts—the saving in cost was not very great for small sizes, but for 11,000 and 20,000 volts it was considerable, as the pressure had little influence on the cost of overhead lines. This saving is often increased by saving in length in open country where roads are few. The chief disadvantages of overhead lines cited were the difficulty in obtaining way-leaves, and the results of their greater inductance owing to the conductors being further apart. The increased voltage drop, on this account, in the case of heavy mains, may be sufficient to necessitate increased section of copper or a reduction in the radius of transmission at a given voltage; there is, however, one important exception, viz., D.C. traction systems supplied through rotaries arranged to take a leading current at heavy load. If cable and overhead mains of equal section are converted in parallel, the different inductances causes the current to divide unequally. This not only prevents the two circuits being run at their most economical current density, but also, owing to the resistance losses being dependent on the square of the current, they are greater than if the current were divided equally. Further, owing to the difference in the inductance of the parallel circuits, there is a phase difference between the currents in the two branches. This results in the arithmetical sum of the currents in the branches being greater than the total current, thus causing additional resistance losses and a reduction in the carrying capacity of the circuits. To take a concrete example, assume that 300 amperes at 6,000 volts and 50 cycles is to be transmitted through a 0·15 sq. in. cable and a 0·15 sq. in. overhead line in parallel. The actual current in the cable will be 210 amperes, and in the overhead line 105 amperes, while the resistance losses are increased by 24 per cent. as compared with the losses if both circuits were either cable or overhead line.

Switchgear was next dealt with, and it was pointed out that it must not be proportioned merely in accordance with the capacity of the apparatus which it controls: its primary object is to isolate faulty apparatus and to interrupt or prevent heavy short-circuits. The breaking of a heavy short is similar to the detonation of an explosive, and, if the switch is badly designed, the tank will be blown off and the whole switch wrecked. The cause of this is the rapid generation of gas beneath the surface of the oil, and consequently air cushions and vent-pipes are not always sufficient safeguards, as, owing to the inertia of the oil, a high local pressure is transmitted hydraulically before the oil has an opportunity of moving at its free surface. A switch designed by Messrs. Hunter and Shand to overcome this by accelerating the break (Patent 11,586/1912) is arranged to draw out two arcs electrically in series, but disposed parallel and close to each other, so that a repulsive effect proportional to the square of the current is exerted. The author does not approve of the use of reactance coils except on the generator mains.

Other points in connection with switchgear mentioned in the Paper were the desirability of limiting the number of potential transformers and always connecting them to the bus-bars through an oil-switch; the interlocking of main oil switches and isolating links; and the interlocking of the guarding arrangements or screens with the switchgear mechanism. An arrangement to facilitate the routine earthing of feeders was also suggested. By using permanent earthing switches it is a simple matter to interlock at the earthing end so as to ensure that the earthing switches cannot be closed until the oil-switch is opened, and vice versa.

The author next investigated the problem of the most economical section of mains, and showed that the law that the most economical section is that at which the sum of the annual charges and the value of the energy lost is a minimum, is commercially applicable to cables of high-pressure distribution systems. The annual charges taken for underground and overhead mains at various voltages are shown in Fig. 1. These are based on average commercial prices, allowing interest at the rate of 5 per cent. per annum, and depreciation at 2 per cent. for underground mains, and 3 per cent. for overhead mains, suitable allowance being made for trench work in the former case, and for wayleave charges in the latter. With compound interest at 5 per cent. the rates allowed for depreciation are sufficient to enable the underground mains to be replaced after 22½ years

and the overhead mains after 17½ years, allowing a scrap value of 20 per cent. in each case. In the case of overhead mains only one curve is given, as up to 20,000 volts the only difference is in the insulators, and this is very small. The only losses important enough to be taken into account in this investigation are the resistance losses and their effect on the load factor of the system considered as a whole. It is pointed out that these losses constitute a load which is far from beneficial, as there is no diversity between the curve of losses and the main load curve; in fact, the peaks are accentuated because the resistance losses vary as the square of the load. Assuming a system with a maximum load of 50,000 kw. and an average load factor of

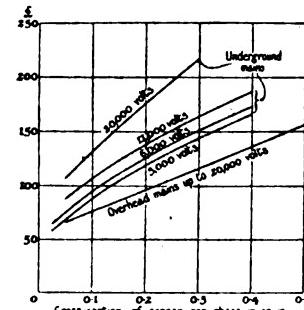

FIG. 1.—ANNUAL COST PER MILE OF INTEREST AND DEPRECIATION FOR VARIOUS TYPES OF 3-PHASE MAINS.

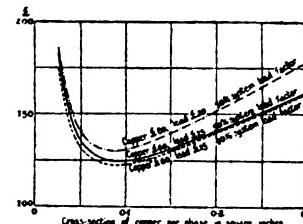

FIG. 2.—COMBINED ANNUAL COST OF INTEREST, DEPRECIATION, AND ENERGY LOSSES PER MILE OF 6,000-VOLT UNDERGROUND MAIN CARRYING A MAXIMUM LOAD OF 100 AMPERES.

50 per cent., and the cost of the distribution system as two-thirds that of the power stations, the value of the resistance losses in the typical system considered is taken at 0·25d. per unit.

By adding the curves of annual charges and value of losses for mains of various sizes for any particular maximum current, a curve is obtained of the type shown in Fig. 2, which refers to a 6,000-volt underground cable required to deal with a maximum current of 100 amperes. The most interesting feature of this curve is that the most economical section is not very definite; it is actually 0·09 sq. in., but for 2½ per cent. increase in the total annual costs the section can be increased 44·5 per cent., or decreased 27·2 per cent., the corresponding figures for 5 per cent. increase in annual costs being 65·5 per cent. and 36·1 per cent. respectively. It follows that it is not sound practice to cut the section of mains too fine, more especially since it is a most expensive matter after a main is once laid to increase its carrying capacity if this should prove too small.

In order to see to what extent the results are dependent on the particular system load factor selected, a corresponding curve has been calculated in exactly the same way but assuming a system load factor of only 40 per cent. This is shown dotted in Fig. 2, and gives a reduction of only 2 per cent. in the most economical section and 2 per cent. in the minimum total annual cost per mile, compared with the original curve. A further curve has been added (chain dotted); this shows that the influence of ordinary variations in metal prices is negligible.

Another series of curves given in the Paper show that up to 11,000 volts in the case of underground mains, and up to 20,000 volts in the case of overhead mains, the voltage makes no difference to the economical cross-section, because, between those limits, the annual charges happen to differ by approximately constant quantities which are independent of the cross-section. Except for 20,000-volt cables, the economical section gives an overload margin of as much as 100 per cent. in nearly all cases, and even for 20,000-volt cables a considerable margin exists.

In discussing the lay-out of the distribution system, the Paper laid stress on the desirability of each sub-station having at least two separate sources of supply, and some form of discriminating protective device isolates a feeder automatically in the event of its breakdown. For this purpose the author advocated unconditionally the balanced-current protective system with pilot wires or the split-conductor protective system. He denied that they really involve extra capital cost, contending that the extra cost per mile was counterbalanced by the saving effected by using an interconnected system. This reduced the number of spare feeders, enabled a number of small feeders to be replaced by a few large ones, reduced the switchgear required, and lastly enabled advantage to be taken of the diversity between the demands of different sub-stations.

The extent to which a system may be safely interconnected by the use of these devices is shown by Fig. 3, which illustrates diagrammatically the high-pressure distribution system on the north-east coast. No less than 350 sub-stations are connected to this system, and it is fed by 15 power stations, many of which utilise waste energy in the form of exhaust steam and coke-oven gas. The older feeders are equipped with balanced-current, and the more recent ones with split-conductor protection. Over a period of time, selected quite at random, faults occurred on 23 feeders equipped with automatic protection, and in 22 cases the faulty feeder was instantaneously isolated without causing

an interruption of supply to a single sub-station except in one instance where a non-duplicate supply was given. In the 23rd case one of the feeder switches failed to open, due to a mechanical fault; this was equivalent to a busbar fault, and brought out the overload gear at two sectioning points, thus limiting the trouble

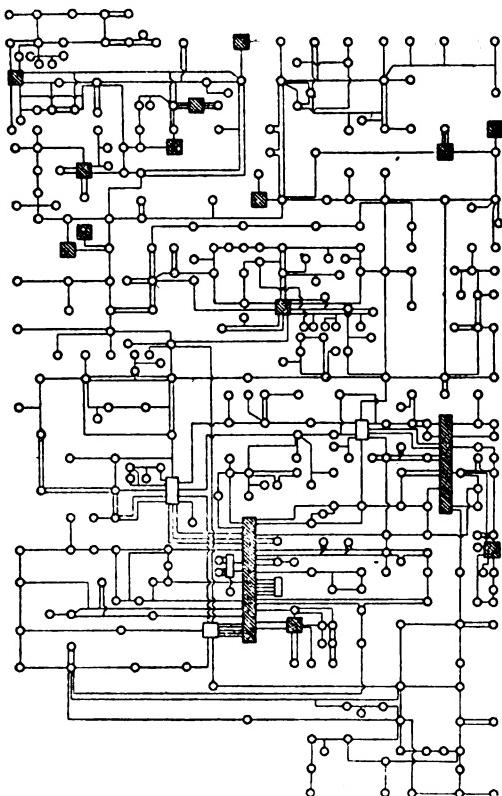

FIG. 3.—NORTH-EAST COAST HIGH-PRESSURE DISTRIBUTION SYSTEM.
(Generating stations shown cross-hatched).

to this section of the system. Actual figures were worked out to prove the author's contention that the saving is not only sufficient to balance the cost of the special protective devices, but that a system so equipped is actually cheaper than systems protected by less efficient methods.

The author concluded his Paper with a discussion of the most suitable distribution voltage.

Mr. P. V. Hunter, who opened the discussion in London, expressed surprise at the low current densities obtained in Fig. 2, which, however, were due to the high load factor taken. Mr. G. W. Partridge was disappointed that pressures above 20,000 v. for underground cables had not been dealt with in the Paper. He was himself considering the use of voltages up to 60,000. He pointed out that lower frequencies than 50 cycles per sec. had advantages. There was less trouble from inductance and capacity, lower iron losses, less danger of surges, and a greater suitability for railway supply. With lower frequencies there would also be a great future for single lead-covered cable. He endorsed the author's remarks as to the necessity for switch-gear being adequate to take the full short-circuit current, and said that he observed neglect of this in the design of almost every station he visited. He was now installing oil switches capable of dealing with 200,000 kw. Oil switches should have as many breaks as possible, and a good head of oil. Referring to the pressure of gas produced in an oil switch, he mentioned one case in which this had been sufficient to blow the switch together again. Bus bars should not merely be supported by porcelain insulators; in the latest switchboard at Deptford he was using single lead-covered cable as 'bus bars.'

Mr. B. Welbourn said that the life of mains had been underestimated by the author; 25 years was now considered a standard for underground cables, and the life of overhead mains was limited by that of the poles; the latter had been put at 35 years by evidence given by the Post Office in the recent telephone arbitration.

Mr. W. B. Woodhouse, Mr. Brazil, and Mr. E. B. Wedmore also spoke, and Mr. Beard replied briefly.

Diesel Engine Users' Association.—At the December meeting of the Diesel Engine Users' Association Mr. G. Porter, Borough Electrical Engineer at Worthing, was elected President. Messrs. C. O. Milton (Maidenhead), C. Gould (Letchworth), and H. Leslie Dixon (Leatherhead) were elected Members of Committee, and Mr. Percy Still (Chelsea) Honorary Secretary. There has been an increase in membership during the year of 19 members, the total now being 48, representing 104 Diesel engines, having a total horse-power of 23,984.

ELECTRIC RAILWAYS

THE "James Forrest" lecture for 1915 before the Institution of Civil Engineers, given on December 14th, was by Mr. H. M. Hobart; it was on "Electrical Railways," and was delivered, in the absence of the author, by Mr. J. A. F. Aspinall. The lecture dealt mainly with the growth of the high-tension direct-current system in America, a system which, as is well known, Mr. Hobart has long championed vigorously against the single-phase system. In some introductory remarks it was pointed out that whereas in 1895 only 8 miles of steam railway (single track) had been electrically equipped, there were now 3,460 miles of converted line running or in process of equipment in the U.S.A. and Canada. Including all kinds of electric railways, the total mileage had increased from 12,100 to 45,000 in the same period. The accelerated growth of the electric railway industry was in no small measure a consequence of, and had also been a contributory cause of, the continual decrease in the cost of electrical energy, and energy was now being supplied to railways on a large scale at prices in the neighbourhood of 0'26d. per kw.-hour. The relative costs of current from steam and water power were considered. The relative advantage depended largely on the load factor. While for very low load factors steam undertakings could supply electricity at the lowest cost, when we came to load factors above 0'2 the hydro-electric undertaking had the advantage, and for unity power factor the hydro-electric undertaking could supply electricity at practically half the price attainable with the steam undertaking. The influence of the variations in the cost of fuel on the total cost was also traced. Roughly, for a 150,000-kw. 11,000-volt steam station an increase in the price of coal from 4s. to 12s. per ton would increase the cost at the generating station from 0'228d. per kw.-hour to 0'302d., to which 0'18d. was to be added for cost of transmission over ten different feeders of an average length of 100 miles, or 0'08d. if all transmitted *en bloc* over one route. These and other figures were only given as broad indications of the order of magnitude involved, and it was remarked generally that higher load factors reduced the investment costs, and consequently also the total cost. The transmission of smaller quantities of electricity is associated with higher costs. Loads with a lagging power factor, unless compensated by loads with a leading power factor, can only be supplied at an increased cost. Every additional transformation of pressure, periodicity, or kind of supply increased the cost. It was an advantage from the load factor point of view and a diversity factor point of view to take power from a system supplying a mixed load rather than for a railway to "manufacture its own electricity."

The first extensive application of electric propulsion to a mountain grade railway system employing a considerable number of freight locomotives was that of the Butte, Anaconda & Pacific Railway, which was described at some length in the lecture, comprising 114 miles of single track formerly worked by steam, and now worked, all but 23 miles, electrically, employing seventeen 72-ton electric and four steam locomotives. The electric locomotives have four 1,200-volt D.C. air-cooled motors of 270 h.p. (continuous rating), connected two in series, capable of delivering 40'5 h.p. per ton of electrical equipment continuously, and developing a 48,000-lb. tractive effort for five minutes. Additional 2-motor tractor trucks can be coupled to them, and the combination can develop a tractive effort of 37,500 lb. continuously at 10'8 m.p.h. The performance of these locomotives was dealt with in the lecture at length, and it appears that whereas when steam locomotives were employed the outlay for fuel and power per loco-mile was 19'9d., the corresponding figure for electric locomotive is now only 7d. The efficiency of the electrical equipments shown by tests is from 83 to 84 per cent., and the "Pantograph-drawbar efficiency" from 77 to 81'5 per cent. The power cost per electric train-mile worked out at 62 per cent. of the outlay for fuel for the corresponding steam train. The improved economy effected by the smaller percentage of time in the repair shops of the electric locomotive and the influence of the reduced number of train crews required are also gone into. The electric locomotives in question required 2'2d. per locomotive-mile for repairs as compared with 6'5d. for the steam locomotives which preceded them.

Some particulars were also given of the Chicago, Milwaukee & St. Paul 3,000-volt lines now being equipped, and special mention was made of the advantages that would be attained by regenerative braking. The fact that ascending or accelerating trains drew their power directly from neighbouring descending or stopping trains was analogous to many additional sub-stations distributed along the route. Reference was also made to the split-phase system with a single-phase

11,000-volt contact line in use on the Norfolk & Western Railway and the locomotives of the New York Central Railway.

Comparing the progress of the single-phase and high-pressure D.C. systems in America, Mr. Hobart pointed out that there were 1,490 miles of the former running against 3,720 of the latter. After going into figures, he argued that we may take the outlay for energy about the same for the two systems, leaving the single-phase system handicapped by the greater inherent cost of single-phase locomotives. If, he continued, up to the locomotive, any material savings could have been demonstrated for the single-phase system, then the correct choice would be influenced by the density of traffic, the greater outlay per single-phase locomotive with a sparse traffic being more than offset by the savings up to the locomotive, while with a dense traffic the greater outlay per single-phase locomotives would more than offset any savings up to the locomotive. Since, however, up to the locomotive, the costs are a stand-off, it would appear that even with a sparse traffic the direct-current system is the most economical, and that the percentage by which it is more economical increases with the percentage which the locomotive investment bears to the total investment.

The conclusions of the Paper were to the effect that: 1st, we are on the eve of the extensive employment of electric locomotives on railroads at present operated with steam locomotives; 2nd, that the direct-current system is the most appropriate; and 3rd, that direct-current locomotives for use from high-pressure contact conductors are now a thoroughly demonstrated success.

COLLECTIVE POWER FOR BRITISH ENGINEERING

THE second of the informal dinners which are being arranged by the British Electrical & Allied Manufacturers' Association in connection with the attack on German trade was held on December 15th. The subject of discussion was a Paper by Mr. T. C. Elder, Hon. Secretary of the British Association of Trade & Technical Journals, who in an address on "Collective Power for British Engineering" discussed the steps which should be taken to deal with the large margin of capacity of machinery in engineering shops due to the war in order that this machinery may not be thrown upon the scrap-heap, but may be utilised to give the electrical engineering trade the right send-off when peace conditions prevail. Mr. Elder, who has almost an undisguised contempt for the Board of Trade as an instrument of commercial advancement, thinks that the first step must be made by manufacturers, and, at any rate, that the organising power must come from them in the initial stages. The necessary first step suggested is for some such Association as the B.E.A.M.A. to endeavour to induce other sectional engineering associations not to amalgamate, but to project a new common organisation for dealing with trade in its broad aspect, leaving individual associations to continue that necessary work in specialising in the affairs of their own particular branch of industry.

In this connection it is not without interest to note that the Institute of Industry is working on somewhat similar lines, but does not appear to be receiving very much encouragement from official quarters. For instance, a scheme for the creation of an industrial bank with a capital of one million pounds—it being stated that the money is available at once—has not been received with much favour by the Treasury, whose suggestion is that it should be put off till after the war. This attitude, of course, completely negatives the whole object of the steps which are being taken in various parts of the country to do something which will place British trade in a better position than hitherto to supply the world's markets, and at the same time defend it against foreign competition of the type to which it has been subjected for many years past. The difficulty at the present moment seems to be that so many people are all working more or less independently of each other with the same object in view, whilst the Board of Trade also is at work on the same lines. The most comprehensive of all these efforts seems to be that of the Manchester Engineers' Club, and whilst everyone knows precisely what is wanted, the difficulty is to evolve some scheme which will avoid overlapping and prevent a needless waste of energy on the part of many people all striving after the same object. To wait until after the war before attempting to frame a policy would be suicidal, and it needs immediate action of the sort advocated by Mr. Elder if the electrical engineering manufacturing trade is to regain rapidly the ground lost through the war.

In the discussion upon Mr. Elder's Paper there was general agreement that the Government, capital, and labour will have to give this matter earnest consideration.

STANDARD WALL PLUGS

THE Engineering Standards Committee have issued a Standard Specification for 5-ampere Wall Plugs and Sockets,* which will cause considerable surprise in many quarters. Not content with giving its *cachet* to the "universal" gauge which is adopted by the majority of consultants and contractors nowadays, they have taken the step of insisting that nothing but the hand-shield plug with wires entering at the side shall in future be standard, and have gone so far as to fix the diameter of the hand-shield at not less than 2 in.

We are strong advocates of the wall-plug with side-entering flex, and the hand-shield type with its handle at the top is certainly as convenient as any for the ordinary front-entry sockets, but we submit that to make this the one and only standard is a grave mistake. There are in use thousands of combined switches and wall-sockets by first-class makers, designed with the sockets at the lower side of the switch base for "universal" gauge plugs, and these will, in many positions, not take the plug with a 2-in. diameter hand-shield. A smaller and far neater plug with side-entering flex, which affords ample protection, is now made by at least one first-class maker; it has pins of "universal" gauge, is in every respect better than the majority of larger and clumsier hand-shield plugs, many of which are of foreign origin, and should certainly not have been left out of consideration as outside the specification.

We have one more criticism to make of the Specification before us. A large number, if not the majority, of the hand-shield plugs on the market rely to some considerable extent on the tight fit of the flex in the hole at the side to prevent the wire from pulling out of the terminals. It is a simple matter to clamp the wire down in the slot at which it enters the plug, but instead of this being definitely specified, a minimum diameter is laid down for the hole or groove, with permission only to use smaller grooves if they are intended to clamp the wire. The Committee have apparently not been aware that many people have rejected hand-shield plugs solely on the ground of the greater risk of the wires pulling out of the terminals than in the ordinary type with top-entering wires.

We would suggest that either the Specification should be withdrawn or that it should be modified at once by deleting the clause calling for a 2-in. hand-shield, and making compulsory, instead of merely permissive, the provision of a device for preventing the wires from drawing out of the terminals if the flexible cord is submitted to a sharp strain.

£350 Damages for Electric Shock.—In the Bow County Court on Wednesday his Honour Judge Smyly, K.C., gave his considered decision in the case of Attwell v. the West Ham Corporation. Attwell was engaged in the electricity department, and his duties consisted of cleaning out transformer chambers. When in one of these at work there was an unexplained explosion, and the man was severely burned, and for some time he suffered from shock. The Corporation denied liability, saying the man was engaged as one who understood electricity, and if he had taken the ordinary precautions nothing would have happened. The case was tried by a jury, who finally gave a verdict for the plaintiff for £350 damages and costs. A new trial was then applied for, on the ground that the verdict was against the weight of evidence, and the legal arguments lasted two days. Judge Smyly, however, said he failed to find any ground for interfering with the verdict of the jury. The jury had had the evidence before them, and, having decided, he could see no reason to upset the verdict. He thereupon ordered the verdict to stand, but granted leave to appeal.

Callender's Staff Service Gazette.—The December issue of the Staff Service Gazette of Callender's Cable and Construction Co., Ltd., needs but a glance for one to realise the extent to which the firm's employees have responded to the call of King and Country. Of the London office staff, 37 have already enlisted and 34 have attested under Lord Derby's scheme, whilst a further 20 offered themselves, but have been rejected. At the Belvedere works 175 have enlisted, and about 400 offered themselves under Lord Derby's scheme, and of the Anchor works staff 64 have already joined the Forces. In addition, 113 of the outside staff have gone, apart from a number who have attested, and the Uxbridge works has also contributed its quota. The Gazette, which consists of some 32 pages, is crammed full of chatty items and extracts from letters.

* For the convenience of our readers we can supply copies of the Specification at the published price of 5s. net, by return of post. Orders, accompanied by a remittance, should be addressed to the Kilowatt Publishing Co., Ltd. Tem Chambers, London, E.C.

QUESTIONS AND ANSWERS BY PRACTICAL MEN

RULES.

QUESTIONS: We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

ANSWERS: A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

QUESTION No. 1,475.

In a small electric bell installation there are pushes in three rooms and a bell with a three-way indicator close to it; the wiring is metallic circuit without common return. It is desired to alter the installation by the addition of two more bells next to the existing one, and the use of a group of three pushes instead of a single push in each room, connected so that a different bell rings for each room, and the number shown on the indicator gives the number of the push used. How can this be done with the minimum alteration in wiring?

(Replies must be received not later than first post, Thursday, Jan. 6th.)

ANSWERS TO No. 1,475.

In a 3-wire A.C. 1-phase network (200 volts across outers) and the neutral not earthed, at normal times the pressure obtained from each of the outers to earth is 100 volts; the neutral, although unearthing, is at earth potential. When one of the outers develops a high resistance earth, the pressure from the unearthing pole to earth becomes 180 volts, from the earthed pole to earth 40 volts, and from the neutral to earth 50 volts. At the same time the normal pressure is obtained across the conductors. Why is this?

The first award (10s.) is given to "M. M." for the following reply:—

The apparently paradoxical condition referred to in the question is due to the fact that inductance and capacity affect the readings and considerably modify the results. With direct current we only have ohmic resistance to consider. In an alternating-current circuit we have inductance and capacity as well as ohmic resistance. It must be remembered that the fault forms a looped circuit. Plotting results as a triangle: Let the base be made to represent the resistance, while the side at right angles to the base represents the difference between the ohmic value of the inductance and the ohmic value of the capacity, it will at once be seen the voltages will, or rather may, sum up to a figure greater than the impressed potential. The explanation is that these voltages are out of phase. Tests on alternating-current systems are not generally reliable as to actual resistances of faults; they are more of a comparative nature. By noting any differences from what may be called the normal readings we can, however, get an indication of faults, although unable to give such faults a definite ohmic value.

The second award (10s.) is given to "F. H." for the following:—

It is difficult to say exactly why "Sulphur" obtains the figures given in the above question, as he does not mention what type of voltmeter he used—whether it was of the electrostatic type or not. Now, an electrostatic voltmeter has an infinite resistance and a negligible capacity, while a voltmeter of the electrodynamic type for measuring up to 200 volts may not have a resistance of more than 3,000 ohms. Further, all the voltages are given in round numbers, so that probably they were not taken with great accuracy. Even at the best, it is difficult to obtain accurate values of such voltages as 40–50 with a 200-volt A.C. instrument.

The line OA in Fig. 1 represents to scale the voltage (100) between one outer and the mid-wire, and OB represents the 200 volts between the outers. If 40 and 180 be respectively the true voltages—measured by an electrostatic voltmeter—between earth and the two outers, they will be represented by the two sides OC and OD of the parallelogram $OCBD$ in Fig. 1. The voltage between the middle wire and earth must consequently be represented by the side OE of the parallelogram $OCAE$. By measurement of OE the voltage is found to be 84, instead of 50 as given in the question; in fact, either the 40 or the 50

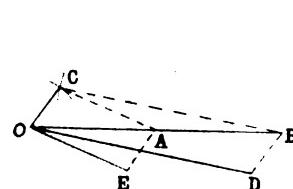

FIG. 1.

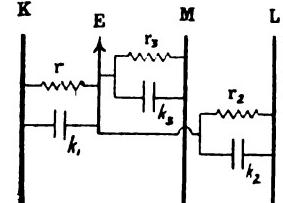

FIG. 2.

volt or both cannot be the true values, since the algebraic sum of two vectors cannot be less than their resultant, which in this case is 100 volts. The employment of another type of voltmeter, however, may be sufficient to partly explain this discrepancy.

In what follows an attempt is made to show how the phase differences indicated in Fig. 1 may be caused by the condenser action of the cables together with a poor insulation resistance between one or more of the conductors and earth. Let K , L , and M in Fig. 2 represent the two outer and the middle conductors respectively. Let r_1 and k_1 be the resistance and the capacity respectively between conductor K and earth; and r_2 , k_2 , r_3 , k_3 be the corresponding values for conductors L and M . Suppose the voltages—measured by an electrostatic voltmeter—between the conductors and earth be e_1 , e_2 , and e_3 respectively. Then, current through $r_1 = \frac{e_1}{r_1}$, and is in phase with the voltage e_1 ; whilst current through $k_1 = 2\pi f k_1 e_1$, and is 90° in front of e_1 . Further, the resultant current flowing between K and earth $= i_1 = \sqrt{\left(\frac{e_1}{r_1}\right)^2 + (2\pi f k_1 e_1)^2}$, and the angle ϕ_1 between e_1 and i_1 is given by $\cos \phi_1 = \frac{r_1}{i_1}$. (For full explanation of these formulæ and vector diagrams see Maycock's "Alternating-Current Work," Chap. II.) Similarly, the earth currents from L and M can be determined. Further, the vectorial sum of the currents at the junction of the three circuits (Fig. 2) must be zero.

To make the above still clearer, let us assume that $e_1 = 40$, $e_2 = 180$, $e_3 = 84$ (Fig. 1). $r_1 = 10,000$, $r_2 = 1,600$, $k_1 = k_2 = 5$ mfd., $k_3 = 4.5$ mfd., and $f = 50$ cycles per second. Then current through $r_1 = 0.384$; current through $k_1 = 0.063$; $i_1 = 0.389$; and $\phi_1 = 95^\circ$. These quantities are represented in Fig. 3, where OF is current through r_1 , and is in phase with the voltage Oe_1 ; OG is current through k_1 , leading 90° in front of Oe_1 ; and OH is the resultant current 95° in front of Oe_1 . Similarly it is found that $i_2 = 0.284$; $\phi_2 = 86.5^\circ$; $i_3 = 0.13$; and $\phi_3 = 66^\circ$.

We can now draw the vector diagram for the currents. Thus, OA in Fig. 4 is the vector of the mains voltage, as in Fig. 1. OP represents i_1 , 95° in advance of OC in Fig. 1; and OQ and

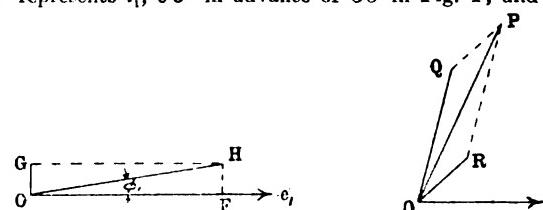

FIG. 3.

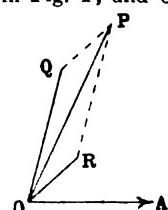

FIG. 4.

OR represent i_2 and i_3 , being respectively 86.5° and 66° in front of OD and OE . The values have been so chosen that $OPQR$ forms a parallelogram; i.e., the resultant of the current flowing between L and M and earth is equal to that flowing between K and earth.

Using a voltmeter of a type other than the electrostatic is equivalent to inserting a high resistance such as r_2 in the circuit, though the insulation resistance of that particular conductor may be perfect. This causes the distribution of the voltages e_1 , e_2 , and e_3 to be upset in different directions when the readings are being taken successively by the same instrument, and may partly explain the discrepancies observed in the figures given in the question.

It may be pointed out that the only effect of an earth on the mid-wire, with perfect insulation on the outers, is to cause the former to be maintained at zero potential, there being neither an alteration in the symmetry of the voltages to earth nor any current flowing through the fault.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 23rd, 1915

A full list of electrical patents published last week appeared in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

4,345/14. High-frequency Currents. Soc. MARIUS LATOUR ET COMPAGNIE. Production of high-frequency currents for wireless telephony and telegraphy by transformation of polyphase currents at n/f cycles into polyphase current at $(n+2)/f$ cycles by a dynamo-electric machine having a polyphase winding on its stator, and a single-phase winding on its rotor, the polyphase winding being fed at n/f cycles. (One figure.)

23,171/14. Motor Control. A. H. CURTIS, W. SHORT, and IRANIC ELECTRIC CO., LTD. A control system for operating two motors at equal speeds wherein the field windings are connected in a common series circuit and in series with a controlling resistance, and the armatures are connected in parallel with a circuit comprising the field windings and any selected part of the series controlling resistance. (Six figures.)

23,749/14. Protective System. J. F. WATSON, E. G. WATERS, and CALLENDER'S CABLE & CONSTRUCTION CO. A protective system for ring mains, &c., having an arrangement of pilot conductors and relays for each section so interlocked that while normally there is no complete circuit either electrical or electro-magnetic through any one of the protective conductors, current derived by one conductor from the system through leakage which virtually establishes the circuit of a companion relay controlling a switch at one place will, through such relay, cause current to be conducted to another relay controlling a switch at a distant point. (Six figures.)

1,088/15. Incandescent Lamps. B.T.-H. CO., LTD. A method of freeing lamp bulbs from occluded gases in which the bulb is made of a material of high melting point and is heated during exhaustion to a temperature slightly below that at which deformation due to softening would occur, and continuing the exhaustion at a considerably higher temperature.

Specifications Published To-Day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 6d. each, including inland postage.

Summaries of some of the more important of these Patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BOWDEN and THOMPSON [Protection of cables] 4,585/15.

Incandescent Lamps: SIEMENS & HALSKE A.G. [Vacuum regulation] 14,918/15.

Instruments and Meters: LANDIS & GYR SOC. ANON. [Prepayment meters] 24,013/14; BLATHY [Brake magnets for meters] 24,543/14; HIKELEY [Integrating wattmeters] 1,483/15.

Telephony and Telegraphy: VREELAND [Production of undamped oscillations] 11,555/15.

TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The annual report of the Pacific Cable Board for the year to March 31, 1915, shows an excess of receipts over expenditure of £78,686, which is greater by £12,035 than the figure in the previous year. Owing to the interruption of the Fanning Island cables, due to a raid by the German cruiser *Nürnberg* in September, revenue to the extent of £50,000 was lost. The amount to be provided by the Imperial and Dominion Parliaments is £7,915. Some interesting details are given in connection with the attack by the German cruiser. It appears that the ship approached the cable station flying the French flag and landed a party, who arrested the superintendent, surrounded the station, and trained a machine gun on the office buildings. Having made prisoners of the staff, the instruments were attacked with axes, the engine-house and lighting plant was wrecked by dynamite, and the cables damaged by dynamite at low-water mark, in addition to being cut at about 600 yards from the shore and dragged out of position. The staff had been able to submit brief intelligence of the occupation to Bamfield and Suva before the enemy entered the instrument-room and cut off communica-

Traction: IRVING [Signalling] 229/15.

Miscellaneous: ALLISON and WALLER [Mine signalling] 23,550/14; CLEUET and BOUVEUIL [Ringing apparatus with polarised electromagnets] 23,563/14; GREENE and BRITISH TABULATING MACHINE CO. [Electrical tabulating machines, &c.] 23,566/14; LABOURNE [Mine signalling] 23,743/14; HISLOP [Contact makers for fire alarms] 3,860/15; Ross [Combined hydraulic and magnetic power apparatus] 8,742/15; HOLLAND and BECKER [Mine signalling] 9,777/15.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

DYNAMOS, &c.: GIRARDEAU [DYNAMOS] 16,928/15.

Instruments, &c.: CUTLER-HAMMER MNF. CO. [Resistance thermometers] 15,124/15.

Switchgear: A. G. BROWN, BOVERI ET CIE [Maximum time limit relays] 14,498/15.

Miscellaneous: DR. ING. SCHNEIDER & CO. ELECTRICITÄTS GES. [Pocket lamps] 15,863/15.

Avoidance or Suspension of Enemy Patents

15,128/11. Electrometallurgy. SIEMENS & HALSKE A.G. An application by the Refractory Zinc Ore Treatment Co. will be heard on Dec. 30th. The patent relates to the construction of anodes for zinc reduction of manganese dioxide with the addition of lead peroxide to improve the conductivity.

Amendment applied for

7,235/11. Electrometallurgy. U. C. TAINTON and J. N. PRING. Leave is sought to omit a claim and make other verbal alterations in this specification which describes a process of electrodeposition of zinc, using an electrolyte containing a large proportion of acid, a small proportion of a celloid or gum, and a zinc salt. The claim in question covers the use of this electrolyte in secondary batteries with zinc electrodes as well as for electrolytic purposes.

Amendment allowed

9,282/15. Dynamos. W. LANGDON-DAVIES and A. SOAMES. Leave has been granted to include the name of the Naamlooze Vermoetschap de Nederlandische Thermo Telefoon Maatschappij as an applicant. The application deals with the driving of dynamos, and is not yet accepted.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:-

361/02. Electric Traction. W. M. BROWN. An improved stud for surface contact tramways.

The following are the more important Patents that have become void through non-payment of renewal fees.

Miscellaneous: G. B. BOWELL [Electric clocks] 20,496/09; W. D. WHYTE [Magnetic compasses] 20,537/09.

tion. Immediately the German cruiser departed, steps were taken to restore temporary communication, and remarkable ingenuity and skill were displayed. An ordinary pickaxe was adapted to the purpose of a grapple, and by this means the heavy shore end was partially raised. One of the operators, Mr. Hugh Grieg, is specially mentioned in this connection. He worked under the sea, and secured the end of the cable, thus enabling it to be raised above the sea-level. The special services rendered by Mr. Grieg and the other members of the staff have been suitably rewarded by the Board. Temporary connection was made between the two ends of the cable by means of ordinary covered wire, the fact that the Germans had towed the two ends widely apart making it impossible to bring them together without more suitable apparatus. The fault was eventually repaired by the cable ship *Kestrel*. The replacement of the apparatus, buildings, and plant involved an expenditure of about £5,000.

In notifying the 7 per cent. preference dividend and an interim dividend of 5 per cent. on the ordinary shares, the directors of the Marconi Wireless Telegraph Co., Ltd., express regret that they have not yet been able to obtain from the Government Departments concerned a basis of settlement in respect either of remuneration or compensation for services rendered, for the use of their stations, since the commencement of the war, nor in respect of other matters in which the Government is indebted to the Company. Without taking these matters into account, however, the directors feel justified in declaring the dividends mentioned above.

CATALOGUES, PAMPHLETS, &c., RECEIVED

EDISWAN LAMPS.—A new list of Royal Ediswan drawn wire filament lamps has come from the Edison & Swan United Electric Light Co., Ltd. (Ponders End, Middlesex). In addition to the ordinary shapes of filaments and bulbs, there are several forms of the "Downlite" reflector lamp with separate reflectors. These reflectors are easily attached and secured by an adjustable sleeve, so that the lamp can be used at any angle as may be required for concentration of light. The polar curve shows that the increased downward candle-power with the use of the opal reflector is approximately 75 per cent.

A COMBINED WATER SOFTENER AND HEATER.—From the Lawrence Patent Water Softener & Sterilising Co., Ltd. (Parliament Mansions, Victoria Street, S.W.), we have received a pamphlet relating to a combined water softener and heater, for which considerable advantages are claimed.

TURBINE-DRIVEN CENTRIFUGAL PUMPS.—The turbine-driven centrifugal pumps manufactured by Messrs. Willans & Robinson (Victoria Works, Rugby) are described in considerable detail in a pamphlet just to hand. Whilst the design of these pumps renders them equally suitable for ship or land purposes, it has been influenced chiefly by the more rigorous requirements of the marine practice.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

METAL FILAMENT LAMPS.—The London & Rugby Engineering Co., Ltd. (36-37 Queen Street, E.C.), have issued a new price list of incandescent lamps, including the "White Star" drawn wire metal filament and the "Rugby" carbon filament lighting and radiator lamps. The metal filament lamps are made from 20 to 30 volts, and 4 candle-power, up to 260 volts, and 170 candle-power for ordinary purposes. They are also made in candle or tubular bulbs and as radiator lamps. There is a similar range in the carbon filament lamps.

FINISHING CUTTER.—With the title of the "Gauge-All," Messrs. Vislok, Ltd. (3 St. Bride's House, Salisbury Square, London, E.C.), has introduced an expandable double-ended finishing cutter for internal work, which should have a wide field of application under present conditions.

EXTENSIBLE LADDERS.—From Messrs. J. Heathman & Co. (Parsons Green, Fulham, S.W.) we have received a list dealing with their numerous types of ladders, &c.

CALENDARS, &c.

Our Editor and Assistant Editor have to thank Messrs. Siemens Bros. & Co., Ltd., and Siemens Bros. Dynamo Works, Ltd., for once more presenting them with copies of the now familiar diary and pocket-book, the 1915 copies of which have done such good service.

The Bastian Electric Heating Syndicate, Ltd. (185 Wardour Street, London, W.), is sending to its friends a neat celluloid pocket rule marked in inches and also in metres. Attached is an adjustable calendar.

The Electric Construction Co., Ltd. (London and Wolverhampton), have sent us a useful pocket diary for 1916 in a roan leather case.

A celluloid calendar for 1916, measuring 4 ins. by 2½ ins., and bearing a metric as well as an inch scale, is being distributed by the Key Engineering Co., Ltd. (4 Queen Victoria Street, London, E.C., and Manchester).

A large wall calendar for 1916, containing one sheet for each month, the figures white on a black ground, has been received from the British Thomson-Houston Co., Ltd. (Rugby). Each page also gives the previous and succeeding monthly calendar, whilst typical pictures of the British Thomson-Houston works adorn each sheet.

British Industries Fair.—The Board of Trade have now completed arrangements for holding a British Industries Fair at the beginning of next year on lines similar to those which characterised the Fair held at the Royal Agricultural Hall, London, in May this year. The 1916 Fair, which will be opened on Monday, Feb. 21st, and remain open until Friday, March 3rd, will be held in the buildings of the Victoria and Albert Museum, South Kensington, London, S.W. Only British manufacturers will be permitted to exhibit, and as the trades decided upon include glassware, no doubt manufacturers of shades, &c., for electric fittings will find it worth while to exhibit.

A NEW FERRANTI CATALOGUE

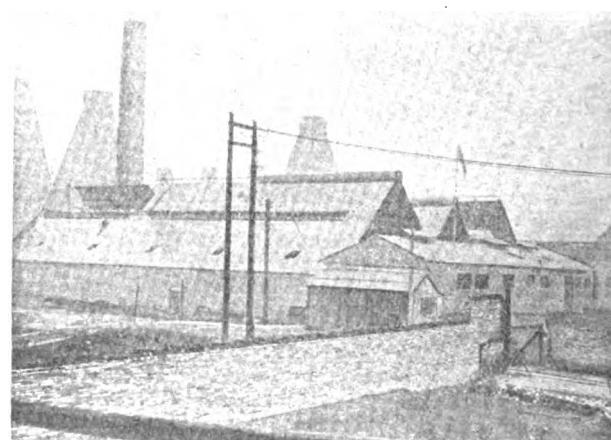

A NEW complete catalogue which has been in preparation for some time past by Messrs. Ferranti, Ltd., Central House, Kingsway, W.C., is now published. It is a comprehensive list divided into eight sections, dealing with house-meters, heating and cooking appliances, transformers, instruments, switchgear, controllers, panels, and sundries. At the beginning of each section is an index and discount sheet giving the dates of issue of the various lists, the discounts, and the advances in price (if any) on previous lists, as well as general conditions of sale. The section on meters includes continuous-current ampere-hour meters for two-wire or three-wire systems and watt-hour meters for two-wire systems, also alternating-current watt-hour meters for various systems of supply. A general description of the meters is given, with diagrams of connections and useful notes on their operation. The list of heating and cooking appliances comprises cone fires, bar fires, cooking discs, boiling plates, grills, ovens, water heaters, and utensils of various kinds, as well as large combined cooking equipments. The heating elements are illustrated and described, and full instructions given for replacing faulty elements or sections of each apparatus. Some useful general notes on the subject of electric heating and cooking are also included.

The section on transformers is mainly descriptive of Ferranti's well-known types. Their standard transformers are all of the core type. Prices can, of course, hardly be given in a list, and these are quoted on application. The next section describes a large selection of instruments, including ammeters and voltmeters of the moving coil, moving iron, and induction types, ampere-hour and watt-hour meters for switchboards, various types of relay, and instrument transformers. The switchgear list is also well illustrated, and describes all the usual varieties, both air and oil switches, as well as fuses of different types. Oil switches of a fairly large size are listed—up to 300 amps. at 6,000 volts, and 100 amps. at 15,000 volts. The controller section is devoted chiefly to starters for continuous-current motors. The division on panels covers starting panels for A.C. motors, and E.H.T. ironclad panels for interlocked, semi-interlocked, and non-interlocked switchgear. Under the heading of sundries are included plugs and sockets for voltmeters and synchroscopes, cable sockets, cable adaptors, equaliser and regulator pillars, and the Ferranti-Field protective gear for three-phase systems with earthed neutral.

The various sections of the catalogue are indexed by projecting tabs, and are neatly bound together in a handsome leatherette binder.

EXTENSIONS TO G.E.C. GLASSWORKS

OUR illustration shows the Lemington Glass Works of the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), where the bulbs for Osram and Robertson lamps are produced. The particular point of interest is that, owing to the con-

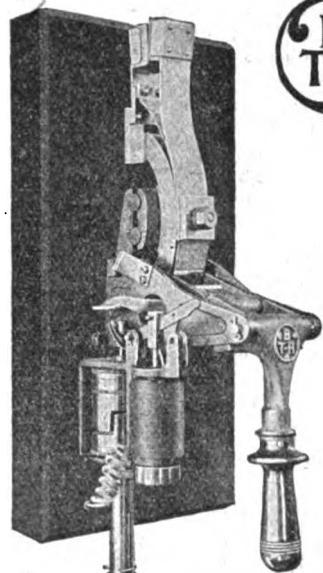

LEMINGTON GLASS WORKS, G.E.C.

tinued increase in the demand for these lamps, considerable extensions have become necessary. As will be seen, these are actively in progress. A full description of the works appeared in ELECTRICAL ENGINEERING, Vol. X., Sept. 10th, 1914, p. 499.

Uniformity of action

is ensured by the gravity controlled tripping device incorporated in

Type V, form A, Circuit Breaker
with low voltage release attachment.

Circuit Breakers

(Type V)

These breakers cover all the requirements for heavy service on power and lighting circuits up to 4,000 amperes continuous rating, and are characterised by robust construction and thorough reliability.

The mechanism is of the free handle type, rendering it impossible for the breaker to be held closed on a fault or opened slowly.

B.T.H. Circuit Breakers (Type V) can be fitted with low voltage, reverse current, and shunt trips, these attachments being so designed that their addition to breakers supplied without such fittings involves no alteration in either the breaker or the attachments.

Write for free illustrated list EE. 3012 on Circuit Breakers.

THE BRITISH-THOMSON HOUSTON CO., Ltd.

Electrical Engineers and Manufacturers,

Head Office and Works :

Rugby, England.

CONDENSERS

FOR ALL PURPOSES.

Condensers for HIGH TENSION and WIRELESS Work.

High Class Condensers for Telegraph & Telephone Lines.

STANDARDS of High Precision.

Sole Makers of A. L. Dearlove's Patent Artificial Line.

CONTRACTORS TO THE ADMIRALTY.

THE TELEGRAPH CONDENSER CO., Ltd.

Vauxhall St., Kennington Oval, London, S.E.

PATENT LOUD SPEAKING TELEPHONES

COMPLETE INSTALLATIONS FOR

WARSHIPS, MERCANTILE VESSELS,
MINES, POWER STATIONS, ETC.

Adopted by the British Admiralty, Foreign Governments,
the Leading Shipping Companies, and as used in many
Electrical Generating Stations.

ALFRED GRAHAM & CO.,
ELECTRICAL ENGINEERS AND CONTRACTORS,
ST. ANDREW'S WORKS, GROFTON PARK, LONDON.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

Greenock.—A loan of £40,000 is to be applied for by the Electricity Department.

Manchester.—The Electricity Committee require a low-tension switchboard for the Stuart Street power-house. Chief Electrical Engineer. January 5th.

Newton-in-Makerfield.—Some electrical plant is required for the Gasworks. Manager. January 3rd.

Wiring

Darlington.—Electric lighting of Chilton Lane Primitive Methodist Church. Particulars from Wm. Blenkin, 29 Albert Street, Windlestone, Ferryhill.

London: Mile End.—Electric lighting of St. Benet's Church.

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

London: St. Pancras.—New hotel at King's Cross.

Miscellaneous

London: Hampstead.—The Council require one or three years' supplies of electrical engineer's stores. Town Clerk. January 6th.

TENDERS RECEIVED AND ACCEPTED AND ORDERS PLACED

Aberdeen.—The tender of Siemens Bros. Dynamo Works, Ltd., has been accepted for the supply of Wotan, Tantalum, and carbon filament lamps to the Aberdeen Steamship Company for the year 1916.

London.—The tender of Siemens Bros. Dynamo Works, Ltd., has been accepted for the supply of Wotan and carbon filament lamps to the Royal Mail Steam Packet Company during twelve months from January 1st, 1916.

APPOINTMENTS AND PERSONAL NOTES

Mr. R. Allan Brown has been appointed Borough Electrical Engineer at Falkirk in succession to Mr. Harold Ranson, who recently resigned to join the Forces.

The War Department, Military Camps, Southern Command, require Shift Engineers, Station Fitters, Wiremen, and Engine-drivers. (See an advertisement on another page.)

The Newcastle-on-Tyne Corporation Tramways want Sub-station Attendants. (See an advertisement on another page.)

NEW COMPANIES

ELECTRODE COMPANY OF SHEFFIELD, River Don Works, Sheffield. Capital £40,000. To manufacture, buy, sell and deal in carbon and other electrodes used in connection with electric furnaces, &c. The first directors are D. Vickers, and W. Clarke (Vickers, Ltd.), H. Peile (Newcastle Alloy Co.), W. H. Ellis (John Brown & Co.), F. C. Fairholme (Thomas Firth & Sons), J. B. Milne (Hadfields, Ltd.), C. W. Kayser (Kayser, Ellison & Co.).

S. G. LEACH & CO., 15-17 Artillery Lane, E.C. Capital, £20,000. Electrical engineers, &c.

TELEPHONE MANUFACTURING CO., Hollingsworth Works, West Dulwich. Capital £25,000.

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £106 to £108 (last week, £100 to £101).

LOCAL NOTES

Bath: Electricity Accounts.—There was a net profit of £11,439 upon the working of the electricity undertaking for last year, and after taking into account the balance in hand and meeting capital charges, as well as writing off £398 to meter suspense account, decreased value of stores, and charging the wages of permanent workmen engaged on capital work, there is a balance to be carried forward of £1,767. The total number of units sold was 2,006,138, the maximum demand being 1,238 kw.

Dover: Loss on Electricity Undertaking.—It is estimated that the loss on the electricity undertaking for the current financial year will be £2,090. The estimate at the beginning of the year showed a loss of £595, but the restricted lighting conditions have increased this deficiency.

Haslingden: Cost of New Services.—The Electricity Committee has decided that during the continuance of the war—the Corporation having exhausted their borrowing powers in respect of services—the cost of all new services must fall on the consumer except in special cases.

Leeds: Half-Year's Accounts.—For the half-year to September 30th the revenue of the electricity undertaking shows an increase of £6,420 compared with the corresponding period of 1914. Against this, however, has to be put an increase of £8,678 for increased working expenses and £6,307 increased capital charges. The actual deficit for the half-year is £15,252 against £11,686, but there is nothing abnormal in this fact, it having been the invariable experience that a deficit has occurred in the summer half of the year.

Loughborough: Half-yearly Accounts.—The half-yearly accounts of the electricity undertaking show a loss of £1,046. It is to be explained, however, that this is not so satisfactory a test of the condition of the undertaking as the annual accounts. There has been a largely increased output for power purposes, which, being sold at a low rate, does not assist the financial position as lighting, which has not expanded in proportion.

Melbourne: Assisted Wiring.—The City Electrical Engineer has been instructed to report upon a scheme for wiring premises on a system by which the cost will be repaid in monthly instalments. The reason for this proposal is that inquiries have shown only 25 per cent. of the buildings in Melbourne are lighted electrically. There are some objections to the scheme, first on the ground that companies who have carried out this form of assisted wiring have almost in all cases been unsuccessful, and secondly, on the ground that it involves competition by the Corporation with wiring contractors.

Weymouth: Electricity Accounts.—The accounts for the year ended March 31st, 1915, show that although there was an increased output of 57,000 units, the loss on the year amounts to £252. This, however, has been met out of the reserve fund. The Electricity Committee report that the prospects of the undertaking until the outbreak of the war were very promising, but that the present conditions give little hope of financial success until the war is over.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Victoria Falls & Power Co.—By declaring a 10 months' dividend at the rate of 6 per cent. per annum, less tax, on the preference shares, the arrears of these dividends have been cleared up to the end of February this year.

Companies struck off the Register.—The following have been struck off the Register of Joint Stock Companies:—Collieries Electric Power Development Syndicate, Hydro-Electric Lift & Crane Co.

Russian Electrical Development.—The Electrical Manufacturers Co. of Great Britain, Ltd., has been formed with a nominal capital of £12,000 in £1 shares to develop electrical enterprises in Russia. This Company is a combination of Messrs. Bruce Peebles & Co., Crompton & Co., Lancashire Dynamo & Motor Co., Allen, West & Co., Brook, Hirst & Co., Eckstein, Heap & Co., and Whipp & Bourne. The first directors are J. H. Bunting, E. H. Reeves, H. C. Siddeley, V. J. Moggridge, J. A. Hirst, A. Eckstein, and S. Whipp. The registered address is 28 Victoria Street, S.W.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of 9d. per line (column width). Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of 1/- for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post. Letters should be addressed to THE KILOWATT PUBLISHING CO., LTD., 208-6, Temple Chambers, London, E.C.

APPOINTMENTS VACANT.**CITY OF BIRMINGHAM.****Electric Supply Department.****APPOINTMENT OF SHIFT ENGINEER.**

APPLICATIONS ARE INVITED for the position of Shift Engineer at the Chester Street Generating Station, Aston Manor.

Applicants must have had a sound mechanical and electrical engineering training, and must have had previous experience of a similar kind in a large electric generating station from which extra-high-tension, three-phase and low-tension direct-current supplies are given.

The commencing salary will be £104 per annum, rising at the discretion of the Committee to a maximum of £200 per annum.

Applications, made on Forms which can be obtained from the SECRETARY of the Electric Supply Department, and accompanied by not more than three Testimonials as to experience, ability and character, must reach the undersigned not later than Monday, January 18th, 1915.

R. A. CHATTOCK,

City Electrical Engineer and Manager.

Electric Supply Offices,
14 Dale End, Birmingham.

PLATINUM, OLD ELECTRIC LAMP TOPS, Scrap Platinum purchased for cash. Best price given.—S. W. FRIM & Co., Platinum Refiners, 13 Great Queen Street, Kingsway, London, W.C.

BINDING "ELECTRICAL ENGINEERING."—Vol. X. of "Electrical Engineering" (Jan.—Dec. 1914) closed with our issue of December 31st. Readers can have their volumes bound by their own bookbinder; or, they may send their numbers to THE KILOWATT PUBLISHING Co., LTD., Temple Chambers, London, E.C., carriage paid (with the reader's name and address), and a remittance of 4s. 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad. Binding Cases (including index, but not including binding) 2s. each, or post free 2s. 4d. (Abroad 2s. 6d.) Index alone, 1d. (Post free 2d.).

TENDERS INVITED.**COUNTY OF LONDON.**

THE LONDON COUNTY COUNCIL invites TENDERS for the provision of two steam TURBO-GENERATORS of 8,000-kw. capacity, with AUTO-TRANSFORMERS, &c., for the GREENWICH GENERATING STATION, in connection with the London County Council tramways.

The specification, bills of quantities, form of tender, &c., may be obtained from the CLERK OF THE COUNCIL, at the County Hall, Spring Gardens, S.W., after payment to the Cashier of the Council of £2. This amount will be returnable only if the tenderer shall have sent in a *bona-fide* tender, and shall not have withdrawn the same. The contract documents may be inspected before the payment of the fee.

The person whose tender is accepted will be bound by the contract to pay wages at rates not less, and to observe hours of labour not greater, than the rates and hours set out in the Council's list. Particulars of the Council's Standing Orders as to its conditions of tender and contract are given in every issue of the *London County Council Gazette*. No tender received after 11 a.m. on Tuesday, 12th January, 1915, will be considered.

The Council does not bind itself to accept any tender.

LAURENCE GOMME,

Clerk of the London County Council.

County Hall, Spring Gardens, S.W.

28th December, 1914.

AGENCIES.

NOTICE.

Notwithstanding our recently-published protests, it has come to our knowledge that statements are still being circulated in the Trade to the effect that our firm is German-controlled, and that it is dependent on the Continent for supplies of finished goods.

Such statements are absolutely false, and are circulated either in ignorance of the facts, or with a view to damaging our reputation as a British firm; and we quote herewith the contents of a circular letter we addressed to the Electrical Press early in August last, shortly after the outbreak of WAR.

To the Editor,
Sir,

We should like an opportunity of correcting erroneous statements which have been made in various quarters to the effect that our stocks are dependent on Continental supplies, and that we act as "distributors" for German manufacturing firms.

The exact opposite is the case, for we have no factoring interests, and are essentially an English manufacturing firm.

Our business as Manufacturers of Electrical Accessories was established in London over thirty-two years ago.

Our senior partner is a naturalized Englishman of Swedish birth, whose home has been in this country for over fifty years.

Our junior partners are both London born, the sympathies of the firm are entirely British, and our capital is all invested in this country.

Trusting that you will afford us this opportunity of removing an erroneous impression, which, unless the facts are stated, will prove detrimental to our interests,

We are, Sir, yours faithfully,
A. P. LUNDBERG & SONS.

WARNING.

If, after this date, such statements be repeated and the names of the originators be brought to our notice, we shall immediately institute proceedings for Libel and Damages.

Any assistance given us by our numerous friends in the Trade towards tracing the originators of such libellous statements will be much appreciated; and will be adequately rewarded if a conviction is secured.

We may mention that we have only one alien employee, he being a Russian Refugee lately in the service of our Belgian Agents.

THE "HATFIELD" PUMP

Merryweathers' Patents.

A Client writes:—"The 'Hatfield' Pumps at this Hotel are particularly successful, especially as regards their silent working. In many hotels one stops at, you can hear the hammer of the pumps vibrating through the whole building, which is very irritating to visitors. Many a comfortable night a man spends in his bed at this Hotel, without being disturbed by 'the thump of the pump.'"

ADMIRABLE SITES FOR WORKS, FACTORIES, &c.

THE GREAT CENTRAL RAILWAY passes from the Metropolis Northwards through the centre of industrial England, throwing out its branches Eastward and Westward to the Coast. Its lines run over the great Coalfield which extends into the counties of Lancashire, Yorkshire, Nottinghamshire, Derbyshire and Lincolnshire, thus affording an easily accessible source of fuel supply. This Coalfield is the largest in the British Isles and was estimated by the Royal Commission of Coal Supplies (1905) to cover not only an area of approximately 4,066 square miles, but also to contain not less than forty-nine thousand million (49,000,000,000) tons of Coal.

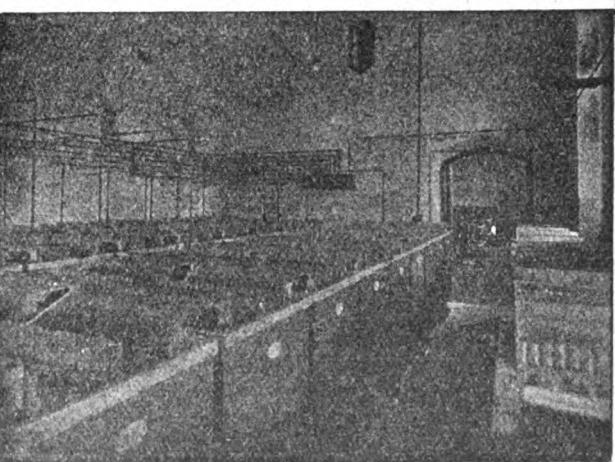

C. THE GREAT CENTRAL SYSTEM is linked up with all the principal centres of industry in the country. The Railway also directly serves the important ports on the East and West Coasts, and the new Eastern port of Immingham should particularly attract traders, as its modern equipment and accessibility at any time of the day or night, irrespective of tides, are important time and labour saving factors.

C. ADJOINING THE GREAT CENTRAL RAILROAD at various parts of the system are situated valuable sites for works, where, by the introduction of siding accommodation, goods can pass right into and directly out of the works, which greatly assists the Manufacturer to attain his desired position in the World's Markets.

C. For information please communicate with the G.C.R. Publicity Office, 216, Marylebone Road, London, N.W.
